DISEASED TEA LEAVES.—KELANI VALLEY, 15th Nov. —I enclose some tea leaves for your inspection. Can you say what is the disease with which they are affected? and also if you can recommend any treatment to prevent further spread of same. [Our usual referee writes:—"I regret I cannot say what the disease is. I do not think it is caused by any leaf-mining insect." We have frequently seen such leaves, but they do not seem to indicate anything serious. —ED.]

COTTON AND TEA PICKERS.—The Charleston (S. C.) *News and Courier* alleges that a practical cotton picker has at last been invented, and stands the test of actual use. This has long been the one great desideratum for the cotton industry, and as the machine in question is claimed to pick cotton in the field for one-seventh the cost of human labor in that direction, the invention is one of great importance. The last crop cost fifty million dollars to pick by hand.—*American Grocer.* [If this is true, a patent tea picker is possible which will, pluck fine.—ED.]

TEA IN NATAL.—*The Field* of October 18th has a contribution from "Mr. Martin Green" on "Tea Culture in Natal" (see p. 471), in which he affords some curious statistics of the crops gathered by Mr. Hulett, M.L.C., who has now 75 acres under cultivation with tea near to Durban. He counts on 800 lb. of tea per acre when 5 years old at a total cost of 6d per lb. for growing and manufacturing, exclusive of interest. A great many other figures are given making out in theory a splendid case; but we should like to have the opinion of an old Natal planting resident on the whole paper:—Mr. Roderick Davidson, for instance, ought to be able to criticize Messrs. Green and Hulett's figures to some purpose, especially in respect of their labour supply.

KADUGANNAWA, 21st Nov.—Black bug will soon, I fear, complete the devastation introduced by "leaf-disease." Both Liberian coffee and Coffea Arabica have suffered much this season from what in olden days in Dimbula was said to be the result of damp and too much rain, but is now supposed to be caused by drought! Estates in their vicinity are looking well. Tea is of course being planted largely, and tea in bearing flushes fairly well. Cacao in sheltered valleys appears to find a congenial home, and very healthy and luxurious the beautiful trees look laden with their richly-colored pods. Cinchona also is coming to the front, and doing well. The proprietor of a small estate down the incline is said to have made a decided hit with cardamoms, and I see occasionally large bundles of roots of this valuable plant being carried down the Pass. I wonder more is not done by the natives of the Four Korales in cultivating this product which pays so well and thrives so gloriously amongst the rich black soil of their rocky gardens.

THE FRUIT-GROWERS OF CALIFORNIA have discovered a new application for the electric light. Many bushels of night-flying insects are killed in their orchards near the cities when the electric light is employed.—*Athenæum.*

CARDAMOM CULTIVATION IN THE COCHIN STATE would seem to be an unprofitable business, if we may judge from the figures given in the latest Administration Report:—*Cardamom Cultivation.*—The total expenditure incurred in this department during the year was R4,612-12-4 against R4,182-2-3 in the previous year. The collections of produce amounted to 1,078 lbs., of an approximate market value of R1,963-11 8, against 1,260 lbs., valued at R2,122 14-3, in the preceding year.

HIGH-GROWN DELICATE FLAVOURED TEAS NOT APPRECIATED IN MINCING LANE?—A tea planter at one of the highest elevations in Ceylon, writes:—"I cannot tell why my tea sometimes fetches the lowest prices in the Tea list, unless it be due to climate; for the brokers' reports pronounce it well made and well flavoured, but wanting in strength. All the tea authorities who have visited me and tasted the tea, pronounce it first-rate—with a most delicate agreeable flavour like the Darjeeling teas and unlike anything else in Ceylon. But I am afraid that to get a price it must be disposed of elsewhere than in Mincing Lane where, apparently, strong, rasping teas to mix with China, sell best."

NEW PRODUCTS: CROTON SEEDS.—This minor new product is beginning to come to the front, for we learn that six barrels of seed sent to London from Wharetenne estate, Haputale, have been described by the brokers as "fine, fresh, of good quality, prices high, supplies scarce, value per cwt. 65s." This will pay rather better we fancy than coffee at the present prices: the shipment was one of 11 cwt; the croton trees in Haputale flourish amazingly and seed freely. Much credit is due to Mr. Holloway of Panwila, who, we believe, is the pioneer of this product, and to Mr. Westland of Golconda who first introduced it into Uva, and who, in the face of some discouragement, has carried on the cultivation until he has been able to make an appreciable shipment of crop.

UNDUE FAVOUR TO COFFEE PLANTERS IN BRAZIL is thus noticed by the *Rio News*:—

Two-thirds of the total revenue of the empire is collected through its custom houses and of this two-thirds, imposts have paid $614,000,000 during ten years, while exports have contributed but $178,000,000. There can be no clearer proof that commerce has been sacrificed in the interest of the planter; burden upon burden has been piled upon commerce and relieved so far as possible from agriculture. In 1882, the famous *addicionaes*, first authorized as a war measure, were increased from 50 per cent to 60 per cent, but at the same time the export duty on coffee was reduced 2 per cent. Merchants and consumers are taxed an additional 10 per cent, while the planter receives 2 per cent, *porque o Brazil é um paiz essencialmente agricola.* It is more than time that commerce should protest against this constant tendency of the legislature to overload it for the benefit of the planter. What would the planter, and especially the coffee planter be without the assistance of the merchant? But, because the *merchant* in Brazil is generally an *estrangeiro*, our conscript fathers think it politic to place on his shoulders every possible burden of taxation, while "long dates and easy amortization" are granted the fortunate planter. It is more than time that *Lavoura* should not precede *Commercio*, and it is our duty, as it is our pleasure, to call the attention of the directors of the Associação Commercial to the position in which the coffee factors are placing them. The Associação Commercial seems nodding, while the Centro da Lavoura e Commercio rules the roast.

Correspondence.

To the Editor of the "Ceylon Observer."

RED SPIDER ON TEA IN SOUTHERN INDIA.

The Neilgherries, 23rd Sept. 1884.

DEAR SIR,—By parcel post I send some samples of diseased tea-leaves, showing what in my humble opinion is either the deposit of the red spider or the green fly. "A Neilgherry Planter," in his *brochure* on tea in Southern India, states that red spider has not shown itself in Southern India. You will notice that the leaves are not all affected in the same manner. Some show clearly the deposit of eggs, whilst others exhibit a sort of film over the leaf which can be easily removed with a penknife. Are they the work of one and the same insect? Only old leaves have been so affected, the young flush being untouched; but the trees show a strong desire to harden their leaves in an abnormal manner so that the old leaves when picked from the bush crackle in the hand like parchment and show a great absence of sap. The weather has on the whole been favourable, but the trees lacked sufficient moisture in June and July.—Yours faithfully, NOVICE.

[We have kept this letter back in hopes that the leaves might come, but they have not done so up to date; so we fear they have miscarried.—ED.]

THE CULTIVATION OF SUGAR IN CEYLON.

Perak, 16th October 1884.

DEAR SIR,—The March and April numbers of the *Tropical Agriculturist* have just been brought to me for perusal, in which I see that the suitability of Ceyon for sugar production is discussed, and my name is mentioned. At page 731-32, you write:—"What the Province Wellesley planters said to Mr. Forbes Laurie is very interesting, but it is a significant fact, that Mr. Wray, author of a standard work on sugar, does not seem to have succeeded practically at Penang. He seems now to be in Government employ in Perak." In making this statement permit me to say that you have been misinformed; inasmuch as I was engaged in tapioca cultivation and *not* sugar cultivation; and moreover I have *never* held any appointment whatsoever, under the Perak Government! I am well aware of your untiring and most valued efforts to uphold and in every way benefit "the planting interest" of Ceylon; and if I can do anything to aid you in that object, I shall be most happy to do so. During my brief visit to your beautiful island in 1879, I was the guest of my most kind and hospitable friend Mr. Forbes Laurie, and was almost wholly in the mountains with him, visiting coffee, cinchona, and cacao estates. Consequently I saw little or nothing of the low-lands In 1847 I was prevented by the sudden leaving of the steamer from accompanying Mr. Black to see his sugar operations near Galle; and in 1879, I regret to say that I omitted to go out and see the sugar estate which I was told, was 10 miles from Galle; hence I have seen no "sugar growing" in Ceylon. I have no doubt however, that sugar cultivation can be most profitably carried on there and that Ceylon will yet *rise higher than it has ever been* by means of *this* great industry, I suppose, I need not say that on a proper selection of lands, and a skilful *laying out* of the estates, success will largely depend? Many, VERY MANY thousands may be lost by want of judgment in these particulars; as well as in the wrong-headed choice of and lavish expenditure on machinery! Those who rush into such matters without sufficient knowledge generally find out their errors when it is too late to remedy them. As the old saying has it, "a thousand and one things have to be thought of" *at the very commencement of the undertaking* to ensure the harmonious and successful working of the whole. If it be thought that my judgment and experience would be useful in this direction I am ready to place my services at the disposal of those who may wish to embark in this important enterprize, simply remarking, that I am thoroughly acquainted with *all* the latest improvements both in cultivation and manufacture.—Yours faithfully, LD. WRAY.

TEA DRIERS AND CRITICISM.

DEAR SIR,—In your valuable number for November an extract from the *Indigo and Tea Planters' Gazette* anent the Messrs. Jackson's tea drier is inserted. Had this article been written in a fair spirit of criticism and less show of advertising business about it, I would not have referred to it. Presumably the drier is equal to or possibly above the average. The majority of planters who like myself wish to procure a really good drier would doubtless prefer plain facts to the use of superlatives and uncalled-for allusions to other makers' manufactures. The machine must stand or fall according to its own merits, and it is for the planter to decide this. A fact is worth more than all the superlative expressions and argument of the childhood's happy day, "It is, because I say it is."—Yours, CATO THE CENSOR.

COFFEE-PLANTING IN NORTH COORG.

High Field, Madenad, North Coorg,
20th Oct. 1884.

DEAR SIR,—We are still having misty weather accompanied with drizzling rain, though I suppose the pucka S. W. monsoon is over. We have registered up to date 160 inches against 181·61 last year, and 274·97 in 1882, so I suppose we may call this a light monsoon. Leaf-disease has been very bad this year, large fields of what was fine old coffee a few months ago being clean wiped out, leaving the trees perfectly leafless. I have only noticed this where the trees were bearing heavily. Of course, this will show up in the outturn, and the result will be, in this district, short crops.

I lately paid a trip to a group of estates on the Perambay Ghaut. The manager (to whose kindness and courtesy I am indebted for a very enjoyable visit), took me around all the estates. I saw no leaf-disease to speak of, and the trees had a fine dark green, healthy appearance, with a very fair crop on them and plenty of wood for next year. One field I particularly noticed looked very promising, which had been manured with a compost of pig, burnt bones, cattle and the sweepings of the town of Verajenderpet. Shade being indispensable, all the bad jāt trees had been ringed or taken out and nothing left but jak, utty and card beven (shingle) trees, the last two especially, as in the monsoon they are leafless, and in the dry weather form a beautiful shade for coffee.

I saw a 50-acre one year old clearing, but though a little wind-ringed (it was being staked) looked very fine, most of the trees being over 3 ft. in height. Those wiseacres who talk about coffee being played out in that district should take a run over and see it. Of course, I don't say that every piece of land is suitable, but if judiciously selected, well-sheltered and good soil with due regard to the economy of the rupee in the working expenses, old King Coffee will pay yet in the forest in spite of low prices. If the celebrated Bambu district of Coorg through the same number of years had had half the bad treatment of the forest, there would have been no estates left by now, and planters must remember, that all the money made in the ghaut and forest went to open the Bambu,

at least the late Mr. Donald Stewart's place. Either the climate of the district is especially adapted for cinchona or that it is a very capricious sort of plant, for I saw a patch of succirubras growing on the top of an exposed ridge on hard gravelly soil equally as well as in a new clearing in a valley, well drained and sheltered.

The cinchonas put out between every second row of coffee were doing very well, and hardly a vacancy to be seen, and the extensive nurseries in preparation for next year's supplies, proved that the proprietors had not at all lost faith in the future of cinchona.—Yours faithfully,

SPENCER MARSLAND.

HELOPELTIS ANTONII AND OTHER BUGS.

Upper Abbotsford 26th Oct. 1884.

DEAR SIR,—I am sorry to say that Dr. Trimen has confirmed our opinion that the colored specimen we examined under the microscope a fortnight ago was a *Helopeltis*. I have an idea that the other green bugs which I sent him are, if not *Helopeltis*, some pest equally destructive; for I found five of them on the affected shoots, and there is some agency at work that can do a good deal of damage in one night, as I have seen to my sorrow the last week. It took me about four hours' personal search to find these five little beasts, so it sounds "sorter ironical" to be told that the only affectual remedy is to catch and kill your enemy. I think I shall indent for a pair of Sam Weller's double-horsepower magnifying glasses. I enclose Dr. Trimen's letter.—Yours faithfully,

A. M. FERGUSON, JR.

(*Dr. Trimen's letter.*)

Peradeniya, 25th October 1884.

Your specimens only arrived this morning. I wish I could say that there was no *Helopeltis* among them. Unfortunately there is one, and one only. This is the larger one on the glass slide, very much injured in the sticking down. This is clearly an immature specimen of *H. Antonii*. The other (green) ones are not that insect, but some other sucking bug which may or may not be injurious.

In the bottle I can find no *Helopeltis*. There were three living insects there. Two were a species of green bugs in different stages of immaturity, the other a black *aphis*. There was also a cast skin of (apparently) the same green bug.

I am very sorry you have had *one Helopeltis* at Abbotsford. Long may he remain a unique specimen! As one swallow does not make a summer, so one *Helopeltis* does not make a tea-blight. But of course you will be on the look-out.

I return the plates from the *Tea Cyclopædia*. The "tea bug" figures are almost terrifying to look at, the animals are so big and so highly coloured! (Very incorrectly also).—Yours very truly,

HENRY TRIMEN.

Helopeltis—*hēlos*—an ornamental nail, pin or stud.

MR. KERR'S HAND ROLLER.

Kinrara Estate, 27th Oct. 1884.

DEAR SIR.—In the report of your correspondent in your paper of 25th instant, on "Tea in Ambagamuwa," I see mention made of an Excelsior roller and a Challenge roller as being at work on Carolina estate, but nothing is said about a roller ordered by that estate from me and sent there a few months ago, and which the V. A. told me, the last time I saw him in Colombo a few weeks ago, was doing its work most satisfactorily. Is there some mistake about this or is at an omission?—Yours faithfully,

H. KERR.

[The list of machinery was supplied by Mr. Meg ginson, but on the way up Mr. Porter spoke favor bly of Mr. Kerr's roller.—ED.]

SUGAR IN CEYLON.

Choisy, Ramboda, 29th Oct.

DEAR SIR,—I should feel extremely obliged if your correspondent "Enquirer," who tells us that Silu Maha Tissa worked a sugar estate near Anuradhapura, would tell me what the Sinhalese word for sugar was in those days, and any other information about the word, such as derivation etc., which may be in his power to afford.—Yours faithfully.

EDMUND WOODHOUSE.

[The passage referred to by "Enquirer" is thus given in Turnour's translation of the Mahāvaṁsa:—"This king sojourned three years near the Sonagiri mountain (in the Ambatthakóla division), working a sugar mill. Obtaining some sugar as the hire of his labour, and taking that sugar, the monarch repaired from thence to the capital, and bestowed it on the priesthood." The Pāli word for sugar is 'guḷa,' a sugar-mill being 'guḷayantaṁ.' The Sinhalese translation of the Mahāvaṁsa renders 'guḷa' by 'uksakuru,' *i.e.*, cane-sugar. The Pāli word 'guḷa' is derived from the Sanskrit 'guḍa,' which means (1) a ball, (2) molasses.—ED.]

CINCHONA AND MARAGOGIPE COFFEE CULTURE IN BRAZIL.

Henaratgoda, 6th November 1884.

DEAR SIRS,—Regarding cinchona and Maragogipe coffee cultivation in Brazil, we beg to annex extract of a letter received by the last mail from our agents there, dated Rio de Janeiro, 23rd September 1884. We think it worth to place before your readers.—Yours obediently, J. P. WILLIAM & BROS.

"Seeds of cinchona have been imported direct from Peru and Chili and distributed by order of the Brazilian Government to our chief planters, who have desired to get them, but seeing that they can make no profit by cultivating this plant, they do care not much about it."

"Maragogipe coffee seeds.—In compliance with your desire and in accordance with your instructions we sent to you 5 cases containing seeds of Maragogipe coffee, no seed of this sort of coffee is to be had, or sold in the market as yet, as the place where the plant grows only occupies an area of 5 to 6 thousand trees, and the seeds are distributed among the chief planters, who are willing to further the cultivation of this bean. Our Mr. ——— has some 200 trees in his estates and the seeds he uses in the reproduction and distributes among his friends."

TEA DRIERS.

Colombo, 6th Nov. 1884.

DEAR SIR.—Comparative statements having been published by Mr. Kindmond and Messrs. Gibbs & Barry as to the capabilities and prices of their respective driers in relation to the "Sirocco," we feel called upon to place Messrs. Davidson & Co.'s new "Sirocco" into direct comparison with these driers for the convenient reference and information of tea planters.

The Kindmond drier works with hot air, and therefore compares with the No. 3 Sirocco.

	Outturn per hour of perfectly dried tea.	Cost f. o. b. England.
Kindmond's No. 1 drier	1 maund	£150
The No. 3 Sirocco	1 maund	£ 90

The Gibbs & Barry drier works with a mixture of air and gases from a coke or charcoal fire, and therefore compares with the No. 4 and 5 siroccos.

	Outturn per hour of perfectly dried tea.	Cost f.o.b. England.
Gibbs & Barry's largest size drier doing about 2½ maunds *three-quarter-dried* leaf per hour, or, as per the tabulated statistics quoted in their pamphlet, for perfectly dried tea, about ...	1½ maund	£275
The No. 4 Sirocco ..	1 „	£ 55
„ 5 Sirocco ...	2 maunds	£ 95

It should also be borne in mind that both the Kindmond and Gibbs & Barry driers require motive power to create and maintain the draft, which in the Sirocco is self-acting.—Yours faithfully,

W. H. DAVIES & Co.

SUGAR IN CEYLON; PORTUGUESE WORDS IN SINHALESE.

Choisy, Rambodda, 6th Nov. 1884.

SIR,—I have to thank you for your answer to my inquiry about the ancient name for sugar. It so happens that an article is already in the press for the *Orient list* having for its subject the Portuguese adaptations by the Sinhalese language; and I was at the moment of your writing tracing out the word in common use for sugar—'sīni.' As it will appear in the second part of the article I will only say here that sīni is the Tamil for China, and 'sīni sarkkarai' has been abbreviated so as to have lost the 'sugar' altogether, for which the 'China' stands substituted.*

Your correspondent, who wants to know where 'rāttala,' a pound-weight, comes from, will find it in Portuguese *arratel*. Any assistance in this connection offered me by *Observer* correspondents will be thankfully accepted.—Yours faithfully,

EDMUND WOODHOUSE.

WHITE-ANTS ATTACKING LIVING TEA BUSHES.

Ratnapura, 7th November 1884.

DEAR SIR,—A short time back a paragraph appeared in the *Observer* doubting the probability of white-ants attacking living tea shrubs. I have seen it (tea) eaten (while green) by white-ants both in Dolosbage and this district, and by this post send a specimen which I pulled up a few days ago, as it may have a conclusive effect. It was full of white-ants at the time. You will notice the stem has been perforated to its extremity, and nearly all the branches the same, yet the plant only betrayed the damage done very slightly: to a casual passer-by little or no difference would have been noticed from the surrounding bushes. Query for savants: why only the low-class hybrids appear to be the ones attacked?—Hoping you enjoyed your holiday, yours very truly, L.

[Our correspondent has not observed, that, apart from its being mentioned long ago in our columns how much trouble Assam planters have with white-ants, there was a paragraph recently describing the serious evil white-ants are proving in a lowcountry district in the Ratnapura direction. We learn, too, that white-ants have been found attacking the living tea as high up as 2,500 feet above sea-level in Ambagamuwa. The strange fact is that young coffee has never been so attacked, and yet tea is supposed to be the hardier plant. There must be something therefore in the tea plant, its wood or pith favourable to the development of the formic acid peculiar to the white-ant. An analytical chemist ought to be able to throw some light on this circumstance. We cannot think that the class of tea, whether China, hybrid or indigenous, makes any difference to the white-ant: it must be chance proximity rather that accounts for particular attacks.—ED.]

*Similar losses are found in English, *e.g.*, *Turkey* (originally Turkey fowl), *damson* (*i.e.* Damascene [plum]), and this very word *China*, originally China-ware.—ED.

EXPERIMENTS IN CACAO AND TEA PLANTING.

Maria, 15th Nov. 1884.

DEAR SIR,—I will have something more to say about cacao, when and how to manure and what manure are most suitable in different soils, &c.

TEA.—I have been quietly experimenting with tea, that is to give body to tea by cultivation, and I find it can be done. In the first place, it will be necessary to distinguish tea bushes from which good strong tea has been manufactured; then take some of the *raw* leaves from these bushes, chew them, do so daily until you can tell by the taste a good leaf at once; note also the colour of the leaves. After you are well acquainted with the taste of the leaves that make good strong tea, *then only* taste other leaves and you will know by the different taste which is deficient, and so can nourish the tea bushes with such manures or other treatment as you may find necessary.

(1) It is well-known where shoots grow *too rapid* the leaves will not make a *strong* tea; in rich soil and a wet climate, bushes should be allowed to grow as high and spread as much as possible; even some of the roots may be required to be cut off, or bleeding of stems may be necessary.

(2) In rich soil and fair climate, tea will want but little help.

(3) Where soil is poor in a wet climate you would have to add manure—quantity and quality must be found out by the tasting of the leaves. Bushes must be kept lower and drain close; in a dry district, make trenches, cheaper and better than terracing.—Yours truly, J. HOLLOWAY.

"THE PARADISE FOR LEAF"; LEAVES STRIKING IN THE FIELD.

Galleheria, Madulkele, 15th Nov. 1884.

DEAR SIR,—The enclosed was found growing in a tea-field here pruned about two months since. Is it possible that the *leaf* has struck? It looks very like it. I can see no trace of there having been a *stem* above the leaf. Knowing the interest you take in our new product, I thought you might like to see it.—Yours faithfully, M. H. THOMAS.

[Mr. Thomas encloses a single tea-leaf with a good long root; but a "struck" leaf is no uncommon sight in Ceylon, and, when cinchonas were very precious at the time of the rush into planting, several planters began beds for striking from leaves as well as cuttings.—ED.]

CACAO PODS FROM THE PERADENIYA GARDENS: CONTRADICTION OF THE STATEMENT THAT UNRIPE PODS ARE SOLD.

Royal Botanic Gardens, Peradeniya 19th Nov. 1884.

SIR,—Under the heading of "Advice to Young Cacao Growers" (page 478), a correspondent goes out of his way to record that he "had no difficulty in at once pronouncing" some pods of cacao sold from the Gardens to a native gentleman to be "not ripe enough for planting." The writer of this piece of impertinence (I use the word in its proper grammatical sense) describes himself as "a practical man,"* and it may be supposed gives the story as a sample of his acuteness in his business.

Now, I should not of course take notice of this method of advertisement, but for this: it is important that the efforts being made by Government to extend the cultivation of new varieties of cacao from the Gardens should not be interfered with by the circulation in the public press of false statements. It is this consideration alone that leads me to think it desirable to put on record positively that the cacao seed in question was quite ripe enough for planting, the best proof of which is that the purchaser reports that they have grown into fine young seedlings, which shows among other things, that, however "practical" a man may be, he is prone to make serious mistakes if he be in too great a hurry to rush into unnecessary criticism.—I am, sir, your obedient servant, HENRY TRIMEN, *Director, R.B.G.*

EARLY MANUFACTURE OF SUGAR IN CEYLON.

SIR,—I daresay many of the readers of the popular *T. A.* are not aware that sugar was cultivated in Ceylon at a very early period. Silu Maha Tissa, the Mahachula-mahatisso of Turnour, having, it seems, learnt that what he earned by his own labour would be a more meritorious offering than any other he could present, worked in disguise as a cooly at a sugar estate near Sva nagari, not far from Anuradhapura, for the space of three years that he might gain a high reward from offering the produce of his labour to the priests.

The article of sugar is frequently introduced by the native writers, but, as may be supposed, it was not made for exportation at this early period, and the cultivation and manufacture of the article was not therefore widely and generally known.—Yours truly,

ENQUIRER.

THE LARGE ACREAGE YIELD OF TEA IN CEYLON.

Colombo, 22nd Nov. 1884.

DEAR SIR,—From what appears in the Indian and English newspapers, the possibility of Ceylon tea estates yielding annually from 400 to 1,000 lb. of made tea per acre is generally disbelieved by those interested in Indian tea estates, because such yields cannot be obtained from the richest Indian soils, and it is broadly asserted that it is impossible for Ceylon soils to give for any length of time the large yields which are being constantly reported in the Ceylon newspapers.

Those who are of this opinion ignore altogether the vast difference between the situation and climate of Ceylon and India, China, and Japan.

Planters in Ceylon know perfectly well, that the large yields obtained by them are not owing to the richness of the soil of their estates, but to the extraordinary suitableness of the Ceylon climate for tea growing.

In India, China, and Japan, tea plucking is confined to about four months in each year, the yield of tea per acre is, therefore, regulated more or less by the state of the weather during the plucking season. In Ceylon, tea planters except during the time of pruning are able to pluck all the year round; they have therefore ten to twelve months to harvest their produce, instead of the four of northern climates.

As a rule, our rainfall is so well distributed, that the yield of one month (when in full bearing) may be taken as a guide to the yield of the succeeding months. Planters are thus able to estimate their acreage yield, with considerable nicety, as it is found, that, if, from occasional periods of dry weather, the yield of one or two months falls short of the average, the recuperative effect of following showers, is so great as to make up for temporary shortfalls. Now, in Northern India, if the weather is unfavorable during any of the four cropping months, deficiencies of yield cannot be made up during the remaining eight months as in Ceylon.

I say, then, that Ceylon tea planters, in their extremely favorable climate, enjoy an advantage over all other countries, but those similarly situated, which more than compensates for supposed inferiority of soil.

It is a moot question, however, whether the Ceylon soils under the influence of a moist and forcing climate is not sufficiently good for a large acreage production of tea; if they are not, the poverty can be economically counteracted without the danger of the disappointing results, which have too frequently attended the high cultivation of coffee. We all know how often the effects of manuring the latter have been entirely destroyed by a couple of days' bad weather during the blossoming time; in the case of tea, such a disappointment would be impossible.

One of the drawbacks to tea-planting in Ceylon is the excessive and constant supervision required. Plucking, manufacturing, packing and dispatching goes on without interval all the year round. The cost of superintendence must be an increasing item as estates come into bearing! And, at the rate tea planting is going on in the island, a very large number of assistant superintendents will be required—one superintendent will be unable to supervise all the work on a large tea estate, and the days of coffee estate pluralities are over.

Considering that tea-making in Ceylon is in its babyhood, the high place which Ceylon teas have taken in the London market illustrates, in a remarkable way, the intelligence and ability of the Ceylon planters to adapt themselves to the altering agricultural circumstances of the colony, and to show how the experience gained during half-a-century in the management of Tamil coolies enables them to carry on cultivation as cheaply as in countries where the cost of labor and food is much less. I think, in a very few years hence, there will be comparatively few complaints of inferiority of qualities from the same district and elevation.

There is no doubt, when skill in manufacture is equalized over the various districts, distinctive qualities arising from difference of elevation will be readily distinguishable. At present what is produced at little over sea-level sells as well as that grown at six thousand feet: the strength of the low country product appears to compensate for the flavor of that of the higher districts, but the time will come when afternoon connoisseurs will be able to appreciate the difference between tea lantana, tea nillu and tea rhododendron. Without having to pay for broken pekoes. Each district will in time have its distinctive characteristics of strength and flavor.—Yours truly, C. S.

DRYING CACAO (COCOA) IN THE SUN: PRACTICAL SUGGESTIONS.

SIR,—I venture to trouble you with a few lines on the principles of cocoa drying by the sun and by heated air. I am given to understand that cocoa dried by the sun fetches 8s or 10s a cwt., more than air dried. It is worth while therefore to endeavour to assimilate air-drying to sun-drying as far as possible.

There is a difference of principle or process in the two methods. The one is expelling vapour by *heat*, the other is drawing off vapour by *dryness* of air. Of course, there is to some extent a combination in both, but in sun-drying, heat is the chief factor. In air-drying, dryness of air is the chief. To indicate clearly the two processes, suppose a cloth dipped in hot water and then exposed to the air, vapour will come from the cloth in a visible form, *i.e.*, vapour will pass

into the air above its point of saturation. Or if the wet cloth were put on a heated stove or held before a fire, all the moisture in the cloth would be dispelled from it in visible vapour, the air around it is filled with vapour beyond saturation. Suppose again we have very dry air, *i.e.*, air very far below saturation. This may be the case either by heating the air or by taking out of it its moisture by some chemical means. In either case, if a wet substance, such as a sponge, were put into this dry air; the moisture in the sponge would pass rapidly and imperceptibly into the air, till it was at or near saturation. In the process of changing into vapour the moisture would take heat from the sponge and leave it cold. So is it with a porous goglet of water when exposed to the action of dry air. The water oozing through the goglet evaporates *imperceptibly* and so cools the goglet and the water in it. The wet bulb thermometer is another example of the same thing. The drier the air the more rapid the drying or evaporation of the moisture on the bulb and the cooler it becomes. Now drying cocoa in the sun is an instance of the former mode, and drying it in dry air an instance of the latter. Let us suppose the average temperature of the air in the two cases is 70° and the wet bulb 5° lower. The cocoa exposed to the sun receives this direct radiated heat and is warmed up to a temperature of 120°. This temperature prevailing in the interior of the "nib" as well as on the surface. This heat, like the case of the wet cloth, sends off vapour into the air even beyond the point of saturation so as, it may be, to be visible. And the vaporizing will take place in the centre of the nib, as well as on the surface. Consequently the nib will be dried pretty equally all through.

By the heated air process, the air is warmed up to 120° suppose. This makes the air *dry*. If we suppose 65° to be still the point of saturation, then the air at 120° will have 55° of dryness. The result is, that the moisture on the surface of the nib passes rapidly into the dry air, while the interior of the nib has to part with its heat in the process, and gets cooled down towards 65°. That it will not reach 65° is probable. Perhaps "W. F. L." or some of the Dumbara savants might favour us with the result of a test of the two by gathering a quarter bushel of nibs from the barbacue, and another from the clerihew and after a few minutes to allow the centres and surfaces of the nibs to arrive at a uniform temperature, insert the thermometer into each heap. If I am correct, I would expect that, supposing the heat of the sun on the barbacue and that of the air in the Clerihew were the same, 120°, the heat of the sun-dried nibs would be higher than that of the air-dried. It would be interesting and perhaps instructive also to have the difference at the beginning, middle and end of each of these two processes.

If I am right about the difference of temperature, it becomes a question how far these two different temperatures *affect the fermentation* of the cocoa. Also if the air dries the outer surface quicker than the interior of the nibs, the outside would be dry while the interior was damp and as the outer surface got dry, the moisture would pass slowly from the interior, and if the cocoa were removed from the Clerihew in this stage, the interior moisture would be apt to spread itself through the whole, making it all to some extent damp and this also might possibly *affect the fermentation.*

If such is found to be the case, the heated air process might be amended by having the cocoa contiguous to a heated surface, which radiates heat into it, as the sun does and so the process of drying by heat might go on simultaneously with the dry air process. Let us hear what the savants of Dumbara and Matale have to say in the matter.—Yours, J. B.

63

CACAO PODS FROM THE PERADENIYA GARDENS.

SIR,—Dr. Trimen may be perfectly correct in saying that the cacao seed in question "was quite ripe enough for planting," but it does not follow that the purchaser of said seed having fine young seedlings, is proof of its having been ripe seed—we all know to our cost that seedlings don't mean plants, and plants don't mean trees. I quite agree with Mr. Holloway that great care is necessary in picking ripe pods for seed, or even for curing and export. A London broker can tell at once whether the pods have been picked unripe or otherwise. So can some of our Colombo storekeepers, who, I dare say, have never picked or cured a bean of cacao in their lives. Dr. Trimen, I dare say, can teach us a good deal, but when it comes to a simple question of a ripe cacao pod, coffee berry or cardamom capsule, I fancy we have little to learn from him.—Yours faithfully, ANDREW POLSON.

NO. II.

Maria, 22nd Nov. 1884.

DEAR SIR,—With reference to Dr. Trimen's letter of 19th inst. in the *Observer* of 20th inst., and his uncalled-for remarks, I have to ask Dr. Trimen the following questions:—(1) Did he (Dr. Trimen) see the pods referred to? (2) How does he know a ripe cacao pod? (3) Is it, or is it not, the fact that when you shake the pod you will hear the seed shake inside of the pod? When you scrape away the light surface-skin of the pod, if ripe, you will find it yellow (not green) underneath—this at least was the test I was told to use by the late Dr. Thwaites when I bought pods from the Gardens and have used ever since when I gather pods for sale or curing and such I do know is the test by all cacao planters. Now in the case referred to by me, I took the four pods; tested and examined them one by one; found on removing surface-skin that it was still green underneath, and, on shaking the pod, the seed did not rattle. I pronounced them not ripe enough to plant, and passed them on to several gentlemen and natives present for examining, so there was no mistake.

I am much surprized that Dr. Trimen should bring forward as proof that the pods were ripe, because the owner reports that the seed has grown into fine young seedlings. There are many planters in Ceylon who can tell Dr. Trimen of the waste of money and time lost by them by having purchased unripe cinchona, tea, cardamom and other seed; the seed did grow into nice seedlings, but how soon did they die afterwards or remain seedy plants and had to be pulled out. By Dr. Trimen's letter, he was aware of these four pods, of new variety of cacao pods, being sold to one man (a rich native); will he now say why European planters who have applied for pods of the new varieties have been told—so I am informed on good authority—they could have plants at twenty-five cents each, but no pods were sold, yet this man got four pods at twenty-five cents each? Great care should be taken at the Gardens to do justice to all orders—ripe seed, healthy plants and distribution of new products. If the test described by me is the correct one, my statement was not false, neither impertinent, but Dr. Trimen's letter was out of place and his remarks uncalled-for.—Yours faithfully, J. HOLLOWAY.

Royal Botanic Gardens, 26th Nov. 1884.

SIR,—Your correspondent Mr. Holloway thinks fit to persist in his erroneous statement, after my deliberate contradiction of it, and attempts to support it by a fallacy. The tests he employed are of course well-known to indicate ripeness in the case of the ordinary cultivated "Ceylon" cacao, but they are inapplicable to the varieties to which the pods

in question belonged. Ir perfectly ripe fruits of the "Cundeamar" cacao, the flesh of the rind remains quite green.

Mr. Holloway may not have been aware of this; if so, the fact should have led him to be more careful in his criticisms. A botanist is little likely to under-estimate the importance of ripe seed. It would however require a good deal more evidence than we possess at present to prove that it is their origin from immature seed that is the cause of the death of *healthy* young plants. Indeed my experience in Ceylon has shown me that many failures are set down to "unripe seed" which are clearly due to quite different causes.

One thing more. In his evident desire to find *something* to say against the Administration of the Government Gardens, Mr. Holloway repeats some story he has heard, apparently with the object of founding on it a charge that natives are favoured in this matter of cacao-pods at the expense of European planters Nothing can be further from the truth. So far as the small stock of pods at my disposal allows me to do so (a first crop on some 30 trees only now ripening), I endeavour to satisfy all applications and to act impartially in the distribution. Very nearly all the planters who have applied have now been supplied with a small number each. It cannot be necessary for me to justify my action in also disposing of some to native cultivators, and I shall certainly not do so at the request of so prejudiced and inaccurate a critic as Mr. Holloway has shown himself to be. So far as I am concerned, this controversy is now closed.*—I am, sir, your obedient servant, HENRY TRIMEN, Director R. B. G.

CEYLON FIBRES.

Kadianlena Estate, Kotmale, 26th Nov. 1884.

DEAR SIR,—I send you a small quantity of fibre (*Hibiscus sena Rosa*) and would be much obliged if you could let me know its approximate value if properly cured. There was no care taken in curing this: the branches were merely pitched into the water and kept there till the fibre came away freely; then washed and dried.—Yours faithfully, JAMES GRAY.

[The sample is a good one though roughly prepared, and is worth probably £20 to £25 per ton; what is the plant—not the shoeflower, "Hibiscus Rosa sinensis"?—ED.]

COST OF TIMBER AT THE STRAITS.—On all sides I hear complaints of the high prices of planks, &c., at the Johore Steam Saw Mills. They say the Company send over their *best* planks to their depôt in Singapore, where they dispose of them at *cheaper* rates. It is evident that these complaints are not altogether groundless; for out of every hundred ordinary half-inch boards for which $6 is charged here and only $5 in Singapore—at the most only 60 or 70 pieces are good for anything. Purchasers are not allowed to select their planks here, but have that privilege at the above-named depôt, or, which amounts to the same thing, the materials in the latter place are already selected for them. This appears anomalous, and Johore customers should have some explanation from the manager to silence their complaints. Good wood is certainly more difficult to obtain now than in former days, but this is no reason for the high prices charged; for the system of advancing money to wood-cutters remain the same, and I am told the Company do not pay much more for timber now than the Mills did in the old days of Tanjong Putri, and the little they lose under this head is commensurably made up for by a more careful method of selecting their timber and a judicious bargaining over rejected portions of "rafta." I notice a gentleman here, who is about to build a house, has been forced by *high prices and low quality* to get his planks, &c., from Singapore brought over in tongkangs. This should not be so.—*Singapore Free Press.*

* And we think further discussion on the subject can serve no good purpose.—ED.

CINCHONA CULTIVATION:

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE THIRD QUARTER 1884.

(Translated for the "Ceylon Observer.")

The past quarter was on the whole very dry. At the end of August several refreshing showers fell, while in the latter half of September also some rainy days were recorded. At the end of July and the beginning of September night frosts were experienced, which did pretty considerable damage to the open nurseries at Tjibeureum and to the plants at Rivenggoenoeng and Kuwah Tjinvidei. On the last-mentioned estate a considerable extent of four-year old succirubras was entirely destroyed. On July 19th the smaller half of the outturn of the harvest of 1883 was sold by public auction at Amsterdam. The prices paid were on the whole very satisfactory, though less than those of the previous year. Slivers of original Ledgerianas realized as much as *f*3·92 per half kilogram, but dust of hybrids—descendants of Ledgerianas—also brought from *f*1 to *f*1·65 per half kilo. The prices paid for pharmaceutical barks packed in boxes deserve remark. Whilst quills 0·5 meter in length, packed in jute bales, could get a maximum of only *f*1·91, for quills of the same length packed in boxes as much as *f*3·02 per half kilo was paid. The total return was *f*201,977·115 gross, or *f*1·045 per half kilo. The harvest of this year amounted to about 250,000 Amst. lb. Of this 204,369 lb were last September sent to Batavia, whilst 2,263 lb were reserved for the military medical service of the island. The harvest for the last few months consisted for the most part of slivers of Ledgeriana descendants, whilst from among the old Calisaya and Josephina gardens only sickly and stunted trees were cropped. It was at first the intention, to dig up on a large scale in the course of this year plantations of inferior varieties and utilize them for the growth of Ledgeriana and succirubra, but the demand for pharmaceutical barks of handsome appearance shown by several sales, has proved the value of these Calisaya and Josephiana plantations, and the uprooting of these gardens will therefore be delayed as long as possible. The outturn of 1884 does not promise to be so large as that of 1883, but it may be expected that the return from the product gathered and yet to be gathered will, by the large quantities of Ledgeriana slivers and the considerable amount of pharmaceutical barks packed in boxes, in spite of a possible large fall in cinchona prices, yield a profit at least equal to that from the outturn of 1883. The supply of labor was scarce only at the beginning of the past quarter. Good use was made of the available forces, so far as funds permitted, for deep working of the soil, the results of which were so plainly manifested shortly after the setting in of the dry season, but especially after some slight showers of rain in the latter half of September. By the continual hunting of the *Helopeltis Antonii* the ravages caused by this insect were reduced to a minimum, and the damages resulting therefrom is consequently of little moment. On July 4th and September 4th sales of cinchona seed were held. The first sale brought *f*3,010, the latter *f*1,542. In July Hr. A. A. Maas Geesteranus was honorably relieved from further acting in the office of Assistant Director of the Government Cinchona Enterprize, and the 2nd class Military Apothecary P. Van Leersum was definitely appointed to the office.

VAN ROMONDE,
Director, Government Cinchona Enterprize.

Bandoeng, 17th Oct. 1884.

CEYLON UPCOUNTRY PLANTING REPORT.

CEYLON TEA PRICES—SALES OF ESTATES—PRIVATE AND CROWN LANDS—ESTIMATES OF TEA HOUSE AND MACHINERY—TEA ESTIMATES.

22nd November, 1884.

The prices which our teas are realizing in the London market are so very encouraging that it is hardly to be wondered at that we hear little else than tea talked. Everybody is becoming an authority more or less and tea tasters are as common as house flies. Just offer a cup of tea to a visitor, and he is caught at once. If he be not critical he is nothing, and, if

you can't get a report in this way gratis, it must be because the visitor has not brains enough to supply it even for a fee. The wisdom that sits enthroned on the faces of some fellows under the influence of an afternoon brew, is almost enough to knock you down with astonishment, when you know the extent of their experience.

I hear that a sale of an estate near Peradeniya has been effected at over R100 an acre. Rumour says that it has been bought by a company of Australian capitalists, for the cultivation and manufacture of tea, under the advice of a well-known colonist who is looking out for investments for this Company. It is said to be a good sale for both buyers and sellers: a fine lay of land, part of it in tea, and several bungalows, and other buildings on the estate.

Land in private hands is so much more easily got, as compared with buying from Government, that intending purchasers prefer as a rule to deal with the former. The worry and time lost in finding suitable Crown land, and then the delays in having the block surveyed and put up for sale are so proverbial, that it is hardly to be wondered at, that applicants are so few, and are often wearied out, and off, ere the cumbrous wheels of Government have done the work that is required of them. If you ask the reasons of what seems such an unnecessary waste of time, you are replied to by a shrug. Certain forms, they insist, have to be gone through: the Survey Department is short-handed—a chronic state it seems—and, if the official you are interviewing be facetious, he smiles at your impatience and mentions years as the average length of time it takes from the date the application is sent in until the block be brought to the hammer. If, in spite of all this, you put a further query, and meekly enquire if there be no way to hurry the matter, you get as an answer: "Possibly, but it is not known in this office." I am convinced, that, if there were fewer delays, there would be more applications for land, and the Government would gain in every way.

I heard an estimate given the other day, for the buildings and machinery for a tea estate of 100 acres, and was somewhat staggering. The sum was R10,000. I have not experience enough to know how near the mark this may be, but am satisfied that many will have to get on with a good deal less, and perhaps all the better.

The example of the big factory at Carolina is going to be followed at Mariawatte, and it is said that the estimate for the new store, with machinery complete, is R35,000. If this be so, it shows what a confidence the owners of that wonderful property have in tea, and what grand profits are made from it.

One seldom hears anything of cinchona now a-days, except that there are enormous stocks of it in Colombo as well as at home. What a fraud it has been; but, then, what enterprize or class of men are not at present suffering all over the world? Things I suppose will right themselves by and by, but we have been long waiting for that revival of trade which was to give all our products a start, and there is not much sign of its coming. It is a comfort that our latest and most promising product holds its position as it does, and long may it continue to do so. The fear is however sometimes expressed that ere very long we will be up to the home demand, and a fall in value be the result. This is possible, but still, when the Ceylon teas get better known, the consumers should multiply: at any rate, if it be true, which I am told it is, that some of the lots of teas which were reported by your London Correspondents the mail before last, netted R1 a pound all round, there is room for a considerable fall, and handsome profits besides.

Touching the value of tea estates in full bearing, I fancy that valuers are but feeling their way yet; still I may mention that one who has been early in the field, and who knows as much about tea as any in Ceylon, says that R1,000 an acre would not be too much to pay for a really good one. Times are "booming" clearly, and the advice of the knowing ones is to "hitch on."—PEPPER CORN.

PLANTING IN JAVA.

The *Java Bode* of the 22nd October, thus depicts the state of the sugar growing interest at Batavia:—Plantation enterprize here, particularly sugar cultivation, is in great peril. It is impossible to describe how unsatisfactory was the state of things, how depressed was the prevalent feeling, and how discouraging was the outlook here during the last few weeks. People who have resided here half a century almost, and are greatly experienced in business matters, do not remember ever having witnessed *such* times. This year will have a black mark set against it in the history of plantation enterprize in Java. Though a few days ago the tidings went round here that the price of sugar in Europe had risen 3 shillings per picul, being thus a ray of light in the darkness, such an improvement in value will be of little avail. The cancelling of consignment contracts by the banks in tens or twenties at a time is the order of the day. Rumours of approaching catastrophes among the planting and mercantile community fill the air. In business matters the silence of the grave prevails. We fervently hope that the Government will be liberal and wise enough to aid sugar growing, now almost at the last gasp by relieving it of taxation and other measures. Every sugar estate which falls betokens a corresponding falling off in prosperity among the people generally. A large portion of the productive wealth of Java and a considerable branch of revenue depend upon sugar cultivation there, and will decline with it.

The *Java Bode's* correspondent, writing from Surabaya under date 11th October, states that owing to falling prices, nine guilders per picul being the rate ruling for sugar classed under No. 14, cane planting has been relinquished on three estates in East Java. On the other hand, he reports that cinchona planters there are realizing satisfactory prices for their produce, and that tobacco cultivators are doing well with every prospect of profitable business in the end unless competition proves too keen. The coffee crops bear a thriving appearance and growers are hopeful from the ruling prices of that article leaving them a slight margin of profit, especially should quotations improve in Europe, of which there is every sign they will do shortly.

ON FARMS AND FARMING.*

PRACTICAL INFORMATION.

"The land be werry honest," as an old labourer said to us one day; "whatever you do put into it, you shall have back again." It was just then coming forcibly home to the poor fellow that all investments had not that merit, for the collapse of the benefit club to which he belonged had deprived him of the savings of years at the very time when he was beginning to need them, and was too old to get admitted into another club—a hard, but by no means exceptional case amongst men of his class, we regret to say. The better you do by the land, the better it will do by you, is repeated perpetually, and the would-be farmer is encouraged to think that he will be quite sure to have back with interest whatever capital in the shape of labour, manure, and seed he may invest in his fields. Nevertheless, in this, as in other investments, there is need of understanding; and if he goes to work ignorantly, he will be apt to make costly mistakes, however zealous and industrious he may be. Perhaps he will rush to the conclusion that as plants do well with a small quantity of potash, therefore they will do better

* *On Farms and Farming.* By George Nevile. Longmans & Co.

with an increased dose of it; or think that clay-land can be dealt with and worked regardless of weather; or put his seed into unsuitable soil; or sow too much seed to the acre; or be guilty of some other blunder which results in the waste of labour, time, and money, notwithstanding the best intentions possible. A farmer is often induced, or rather compelled, by circumstances to deviate in practice from what he knows theoretically would be best to be done if there were no difficulty in the way of doing it. For instance, in manuring, there is not only the chemical effect on the soil and crops to be considered, but also such matters as these:—

"1. The practicability of carrying out the application of the manure. 2. The convenience of applying it at one time more than another, or to one crop more than another. 3. The relative expense of the cost of the manure, and the return it is likely to make. 4. The time which is likely to elapse before the return made by the application of the manure assumes a money value."

For what is the use of putting farmyard manure upon strong clay when the weather is such that the passage of heavily-laden carts would do more harm than their contents would do good? Or how can a man be expected to apply manure at the exact time which is, chemically speaking, the best, if he just then requires all his men and horses for some still more important operation, such as hay or corn harvest? Or is it not likely that some artificial manure, which is generally recommended as profitable, would prove the reverse, supposing the fertiliser happened to rise in price whilst the crop to which it was especially adapted became cheaper? And how far a thing pays is the criterion by which the author believes all farming concerns should be judged:—

"Spending money on a farm is not necessarily a test of good farming, as it may be spent ignorantly and wastefully. Growing large crops could only be considered as a test of good farming, if growing large crops *at any cost* were the object desired. I take it that the test of good farming, like everything else, lies in the amount to which success attends the object to be gained; and as the object of people who have to make their living by agriculture is to make as large a profit *for themselves* as they can, I think the true test of *good* farming as distinguished from *bad* farming is the relative amount of profit for the farmer which is to be derived from it; that is, that any kind of farming which leaves a profit is better than any kind of farming which leaves no profit; or good farming is farming which pays, and bad farming is farming which does not pay. Judged in this manner, it will be seen that high farming may be either good or bad farming, and that low farming may be either good or bad farming."

Mr. Nevile has a good deal to say on the interesting subject of what food it is that various plants require, and in what way and what quantity it should be supplied to them. The three indispensable substances are nitrogen, phosphorus, and potash, which are all found in the earth or air, and to which the plants help themselves by means of their leaves and roots; hence it follows that large-level plants (like turnips) depend much more upon the air for nourishment than small-leaved ones, whilst those with active and wide-spreading roots (like wheat) feed more from the soil than those whose roots are feeble. When it is desirable to increase artificially the naturally-existing supply of either or all of the three necessary articles of food, he says that the rule to be observed is "that there is no special food required by one plant more than another, but that we ought to apply that substance in excess which forms the root in the case of those plants which we grow for their roots; we should apply that substance in excess which forms the *seed* when we want to *obtain* seed; and that where we wish to develop the whole plant, stalk, leaf, flower, and root, as in the case of the clovers, we should apply proportionate quantities of all three, and increase the quantities of all three, *pari passu*—that is, in an equal ratio or degree." Only, in applying this rule, it is important to notice that the experiments hitherto published seem to point to one marked distinction between the aforesaid substances, which is "that although potash is necessary to the development of the plant, and although plants will not grow in soils destitute altogether of potash, even though there may be an abundant supply of other materials, there is still this difference between them, that whereas in the case of the first two, nitrogen and phosphorus, the more you put on, the larger crop you get, this does not seem to be the case with potash, inasmuch as a small quantity seems to have the same effect as a larger quantity. And in cases where the soil contains potash, as in clay, the application of purchased potash does not seem to produce any beneficial result."

We will conclude with a specimen of practical good-sense as evinced in the advice which the author gives respecting the introduction of new implements and machinery, and with which we cordially agree:—

"As there are always plenty of experimental farmers who farm chiefly for amusement and occupation, ready and willing to give anything new a fair trial, I should recommend anyone who was farming for an income to let this class of experiments alone. There is one great objection to employing any new implement when first introduced, and that is that they have rarely arrived at the highest perfection they are capable of; and although they may be a decided success, still, if anyone invested their capital in them, they would probably find that before long a still better one had been introduced, and that they were in the unpleasant position of either having to go on using an inferior machine, or else buy a second, in which case all the money laid out in the first would be wasted. I need not say that this objection does not apply to hiring, but only to buying new implements."—The *Spectator*.

APPARATUS FOR TESTING SEEDS.

It is sometimes desirable to test the quality of seeds by ascertaining what proportion of a given number will germinate; and M. Keffel, a French horticulturist, has contrived a useful "germinator" for this purpose.

A cylindrical vase, contains a layer of water several inches deep. Over this is a curved disk containing a hundred small holes, in which are placed the grains to be tested, the sprouting ends pointing downwards to the liquid. Sand is then placed over the seeds, and the germinator taken to a place free from draughts, where the temperature is kept at 18° C. (equal to about 60° F.), or thereabout; and in twenty-four hours the seeds will be found to germinate. The warmth and moisture are essential to the result. A thermometer rises from the cover to tell the degree of warmth the seeds experience. By counting the number that do or do not germinate, the percentage of good seed in the sample may be at once determined.—A person with moderate ingenuity could easily make the apparatus for himself. For the curved disk he might use a piece of tin punched with holes, after the manner of a common strainer; and the other parts might easily be extemporized from materials to be found in any household.—*Popular Science News*

ONE of the best means of protecting cucumber, melon, and squash vines from the striped bug is by dusting them freely and frequently with fine dry slaked lime.—*Indian Agriculturist*

GINGER IN JAMAICA.—It is stated in authoritative quarters that the cultivation of ginger in Jamaica is diminishing very notably. An official report says that the decrease during the past five years has averaged about one-third of the former crop. The cause is said to be the constant planting on the same soil year after year.—*Monthly Prices Current.*

BRITISH NORTH BORNEO.—During the last month (August) a party of Chinese Gambier Planters' representatives arrived from Singapore and inspected several portions of land near Sandakan Bay, with a view to open up the country for Gambier cultivation. They stated, however, that, without more inducement, they could not take up land. Their view was that the Government should advance money, and grant leases on very easy terms. They considered that Borneo was at such a distance from a port where they could sell the gambier to advantage, that the attraction in the good soil was not so great as to induce them to enter upon making plantations. It seems a pretty general opinion that, unless the country is cultivated by Chinese, nothing will come of agriculture, as the success of tobacco and some other products is still an open question from a practical point of view.—An unfortunate affair

AGRICULTURAL ITEMS.

Above all things avoid foul seed.

Gas lime should not be used fresh.

Roll the ground before and not after seeding.

Good seed and good soil are a good beginning.

Turkeys suffer much from hot weather. Let them have plenty of water.

Oil the inside of horse collars after thoroughly washing them with carbolic soap, which both cleanses and disinfects.

The farmer who has first-class farm implements is justified in disliking to lend them. They are never so good after they have been borrowed.—*Sydney Mail.*

OIL OF SUN-FLOWER.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—In your issue of the 22nd instant, your correspondent "A Scientific Traveller" has rightly informed you that I purpose making experiments with the sunflower plant (*Helianthus annus*) on a large scale, on the Vaheedpoor farm. I shall be highly obliged if you or any of your readers (especially Europeans) will be good enough to reply to the following queries:—

For what purposes is the oil of sunflower used in the British Isles and on the Continent of Europe?

Does the oil find a ready market? If so, what is its market value?

Could the oil be used for culinary purposes without any injury to health?

S. COOMARASAWMY MOODELLIAR,
Superintendent of Vaheedpoor Farm.

SIR,—In reply to the inquiry of the Superintendent of the Vaheedpoor Farm, regarding the oil of the sun-flower plant, I have the pleasure to intimate that the seed is valuable in feeding sheep, pigs, poultry and other animals; it produces a striking effection poultry, by occasioning them to lay more eggs, and it yields a large quantity of excellent oil by pressure. The leaves furnish fodder for cattle, and the dry stalks burn well, the ashes affording a considerable quantity of alkali. When oil is extracted from the seed, the oil case makes excellent food for live stock and poultry. The oil is sweet, of an agreeble taste, and nearly inodorous. It may be substituted for olive oil, and can be introduced for culinary consumption, lamps, and manufactures. When the seed is not well husked, the husks absorb the oil. The seeds should be exposed to the sun, thoroughly husked, and subjected to the mills; each flower should produce one pound of seed, and an acre one thousand pounds of seed, or two hundred and fifty pounds of oil. The seeds may be sown in a nursery, and transplanted when four or five inches high, in rows, or at once sown in rows, and watered every other day for four or five days, the time it takes the seed to germinate. The flowers must be collected just as they begin to fade, and the seeds should be well dried. A French bean may be set at the foot of each plant.—A.

SIR.—In reply to the enquiries of the Superintendent of the Vaheedpoor Farm, your correspondent "A" writes that each flower should produce one pound of seed, and an acre one thousand pounds or 250 pounds of oil. I think it is impossible to obtain one pound of seed from one flower. Rather the correspondent must have meant "one flower" instead of one plant; one plant gives several flowers. I once planted this plant, which produced about one hundred flowers, and the yield there from was about two pounds for each plant. If we take the yield of one pound to be for one plant, one acre must contain only one thousand plants, according to the calculation of "A," or one plant to each 43½ square feet, or 6½ feet apart. This distance is used for large plants, such as casuarina, &c., but is too much for a sun-flower plant. I remember seeing in the *Indian Agriculturist* that an acre of sun-flower plants contains about 10,000 plants and yields half a pound per plant or 5,445 pounds of seed per acre. I think this calculation is also excessive. I think one plant to each 9 square feet, or 4,840 plants to an acre, and the yield 4,840 pounds, at one pound from each plant, seems to be a fair calculation.

THE POSITION OF GUM KAURI.

Although the market for this important varnish gum has undergone no change for some time, the position of the article has latterly been growing stronger and the prospects now point to an early advance. The stock of kauri on hand in London on the first of July was only 784 tons against 1,719 tons at the same time in 1883, showing a decrease of nearly 1,000 tons. As London supplies all Europe with this gum it is plain that London will have to draw largely upon the Auckland market, and an advance in the latter market may be looked for, the dealers there knowing the statistical position in London, and are already holding out for better offers. This will naturally cause an advance in London, which will be followed by higher prices here. At the prices now quoted in this market importers cannot sell to arrive at a profit, and with an increased cost at Auckland an advance must follow. The position, therefore, is much stronger than for some time, and with only moderate stocks in the United States, and these almost exclusively in first hands, consumers would do well to take advantage of present opportunities to purchase at current prices.

The statistics of the London market, aside from the stock, are interesting, as showing the tendency to higher values. There was imported into London during the first six months of the present year 1,240 tons against 1,403 tons during the first six months of 1883, and this, with an increased consumption, would in itself tend to strengthen the position, even though a considerable surplus had been available. We find that the deliveries during the first half of the present year were 1,339 tons, while during the first six months of 1883 they were only 1,091 tons, an increase of 248 tons, and this is believed to represent the increase in consumption. Ordinarily the London dealers carry a six months' supply, while from the figures representing the consumption for the past six months it will be seen that they have only a three months' supply. Here the position is very similar, the supply being estimated as about sufficient to meet four months' requirements, although some dealers claim it is smaller, and that should a considerable increase in demand be developed during the next two months we should be compelled to draw on the London market for supplies. At the last auction sale in London 1,780 cases were offered and 1,243 cases were disposed of at prices fully up to the highest realized at the previous sale, while the bidding was spirited, indicating that the bidders were in actual need of supplies and that they had confidence in the article. Selected scraped realized £10 5s. per cwt., while common grades were sold at an advance over previous prices.—*Independent Journal.*

SETTLING ACCOUNTS WITH THE GARDEN VERMIN.

Now it is no part of our commission to scold people. Our duty and our pleasure is, and will be, to help them. Therefore, in this time of roses and green fly, we will compress into a few words the sum of our experience in a run of nearly forty years of experimental gardening. It is this:—If all that is needful to ensure healthy and vigorous growth is provided for plants (of whatever kind), they will pretty well take care of themselves as regards the vermin. It will be found that the sickly plants are first attacked, and the poor leangrowing things seem always to invite the vermin. But this is not to be understood as a general indictment implying that wherever the vermin are seen the general cultivation is faulty. By no means is such a positive conclusion to be deduced from negative evidence. As accidents will happen in the best regulated families, so vermin will appear in the best kept gardens and on the most vigorous and healthy plants. But when all reservations and exceptions have been taken into account, the golden rule remains, and should be ever kept in mind, that the vigorous and healthy growth of plants is the surest protection against the insects that assail them. When you plant, therefore, have the ground well made up for the purpose, and when you give water, imitate the sound logician and go to the root of the matter. You will hear of insecticides innumerable. But amongst them all tobacco is the leading nostrum, and tobacco and sulphur are often combined. But there is at every amateur's command a very

cheap and effectual insecticide in the shape of water, and a nice shower from the engine or syringe, combined with occasional watering at the roots, will do wonders for roses, for insects, generally speaking, hate water; it is deadly to them. But there is a matter of special interest and importance in connection with the use of water. It is that *hot* water is more deadly to insects than cold water, and all kinds of plants may be sprinkled or dipped in hot water without injury, provided only it is not too hot. You may, by using a trusty thermometer, make a safe rule, and use the water at from 120 deg. to 140 deg. of Fahrenheit, and with this simple agent you may deal out death to the vermin and life to the plants—a very curious example of killing two birds with one stone. In practising this plan, a few careful trials should be made. Trust not your hand to know how hot the water is, for you may make a mistake and hold us responsible for the consequences. Provide a bucket of hot water and stir it well about, and by adding hot or cold bring it to 120 deg. Then take a few pot plants, such as fairy roses, primulas, &c., and dip them head downwards, so as to wash the leaves, and move them up and down a few times, and then set them aside, to drain. They will be none the worse for it, and the green fly will be completely washed from them.—*Amateur Gardening.*

THE RAVAGES OF GRUB.

From the Right Hon. the EARL OF DERBY to His Excellency the Hon. A. H. GORDON, G.C.M.G.
Ceylon.

No. 297. Downing Street, 6th Oct, 1884.

SIR,—With reference to my despatch No. 223 of the 15th of July, I have the honour to transmit to you a copy of a further letter from Mr. Thiselton Dyer, enclosing a copy of a report made to the Government of Bengal on the insect, the ravages of which have been mischievous in the coffee plantations of Ceylon. I am, &c,

DERBY.

Enclosure.

KEW GARDENS TO COLONIAL OFFICE.

Royal Gardens, Kew, 23rd Sept. 1884.

SIR,—Referring to my letter of July 1st last, transmitting to you a report by R. McLachlan, Esq., F.R.S., on the ravages of "grub" in the coffee plantations in Ceylon, and calling attention to a similar visitation which had completely devastated the public garden at Darjeeling, I am now desired by Sir Joseph Hooker to transmit to you, for the further information of the Ceylon Government, the accompanying copy of a report to the Government of Bengal on the insect which appears to have done the mischief in India.

For a copy of this valuable document Sir Joseph Hooker is indebted to Dr. King, the Superintendent of the Calcutta Botanic Garden, who is now in this country. It has been drawn up by Dr. Anderson, F.R.S., the well-known Indian Zoologist, and Sir Joseph Hooker believes that, taken in conjunction with Mr. McLachlan's report already in your hands, it practically exhausts the information attainable on insect ravages of this type.

I am, &c.,
W. T. THISELTON DYER.

Sub-Enclosure.

From the HONORARY SECRETARY, Zoological Gardens, to C. W. BOLTON, Esq., C.S., Under-Secretary to the Government of Bengal.

No. 398. Zoological Gardens, Alipore, 28th Oct., 1883.

SIR,—I have the honour to inform you that on the receipt of your No. $\frac{1}{3}\frac{3}{5}\frac{5}{5}$ F., dated the 9th May last, I forwarded specimens of the cockchafer in question in all its stages to the British Museum for identification, as stated in paragraph 6 of Dr. King's letter dated the 28th May, 1883.

Since then I have been anxiously waiting for the information for which I asked, but I regret to say that I have received no reply as yet. I have, however, sent Dr. Gunther a reminder on the subject.

With regard to the information called for in your letter under reply, I would first point out that all my knowledge regarding the history of this pest at Darjeeling is derived from the reports forwarded to Government by Mr. A. T Jaffrey and by Dr. King, and I have no personal acquaintance with the ravages committed by the cockchafer.

First, as to the probability of any danger to the plants resulting from these grubs. Dr. King's experience recorded in his letter is an illustration of the danger that may arise from sending out plants from the soil of a locality, such as the Public Garden at Darjeeling, impregnated with eggs and larvæ of this beetle. Tea plants, as is well-known, have no immunity from the attacks of vegetarian beetles in their two stages of larvæ and imago, so that were this cockchafer accidentally introduced into a tea garden, it would in all likelihood attack the tea bushes in the same way as it does shrubs and vegetables of the most diverse characters and properties. In Europe, allied cockchafers also seem to know no limit to the variety of their diet. Whenever these insects occur indigenously, there is always the danger of cycles of increase occurring among them, during which they occasionally destroy nearly the entire vegetable life of a district. These cycles are again followed by periods in which the numbers become immensely reduced, and the pests practically disappear. This has been the experience in Europe and America. These periods of increase are brought about by certain conditions favouring the deposit and rapid hatching of the eggs and the vitality of the newly escaped larvæ. One of the conditions which has been ascertained to conduce to the spread of the species of the group of *Melolonthidæ*, of which the cockchafer is a member, is the presence of manure or decaying animal refuse, and I have therefore very little doubt Mr. Jaffrey and Dr. King have rightly explained the cause of the sudden appearance of the beetle in such vast numbers at Darjeeling. As to whether there is any reason to apprehend danger to the tea plants in Sikkim from this pest, I can only say that if the centre of infection is not efficiently removed, danger must be apprehended; as the species if allowed to go on increasing in numbers, even for a limited period, must of necessity extend its range. Every means therefore should be taken to free the soil in the Public Garden from the larvæ, and measures should be taken to destroy the insect. In Europe the following methods are pursued for this purpose:—1. Collecting the beetles. This may be done by picking them from the low bushes and by shaking them from the trees in the plantation on to sheets spread underneath as practised in the forests of Germany and France. Smaller trees are shaken by the hand, whilst the beetles may be precipitated from the larger trees by a smart blow with a heavy hammer against the trunk. Trees which stand singly or at the edge of a plantation, and the leaves of which are eaten by the beetles, shelter generally the largest number. The early morning is the best time for collecting the European species as they are then most torpid. In the evening and during the night they are in full activity. 2. Collecting the larvæ. Care should be taken to destroy all grubs found in manure heaps and in manure when it is spread out over gardens. 3. The soil also should be frequently ploughed or dug up, and the larvæ should be sought for and destroyed. In nurseries and in vegetable gardens, when the plants are in rows, the grubs generally follow the rows, making their progress by the dead plants above ground, and in such cases the grubs will generally be found near the plants that last died. 4. All birds feeding on the perfect insect, such as crows, jays, magpies, &c., should be strictly preserved; likewise shrews and moles, which feed on the larvæ, and also such carnivorous ground beetles as the *Carabidæ*.

I may add that the beetle which has done so much damage in the Public Gardens, Darjeeling, has been determined here as *Lachnosterna servata*, but this indentification requires to be verified. Little or nothing is known of its life history which will probably be found in its broad outlines to correspond to that of its European and American allies, *Melolontha vulgaris* and *Phyllophaga fusca*.

The former *M. vulgaris* requires three or four years for its complete development from the egg to the death of the perfect insect but Mr. Jaffrey seems to think that the life of the Darjeeling species is limited to a much shorter period. This aspect of the history of this pest requires careful observation. M. Reiset in his investigations on the ravages of *M. vulgaris*, presented to the Académie des Sciences in 1868, found that in France the larvæ of that species takes two years to complete its growth to the pupa stage, fourteen months of which are spent in active feeding and ten months in dormant hibernation. The duration of the pupa stage he found to be eight months, and that the adult cockchafer lived for three years and a-half.

Observations in Germany would seem to prove that the life history of some species may be extended from three to four years. The females deposit their eggs in the soil, burrowing into it for about 8 inches, and laying about 40 eggs. She prefers a soil which has been loosened by cultivation to a hard soil covered with vegetation. Manure heaps are a favourable place for depositing the eggs, and the pests in Europe are often spread over a district by using a manure intected with the eggs, or with the young larvæ.

The larvæ, which remain small during the first year of their lives, begin to do serious damage in the second year by eating the roots of all sorts of plants and grass, cereals as well as shrubs, and young forest trees. In the winter of the second to the fourth year (according to the climate) they are transformed into nymphs, and the beetles make their escape in the following May.

The winged insect is also most destructive to vegetation during its brief lifetime, stripping the trees of their entire foliage. In 1866 the damage done in the Department of Seine Inférieure by the larvæ and perfect insects of the *M. vulgaris* was valued at one million sterling.—I have, &c., JOHN ANDERSON, *Honorary Secretary.*

IF cut-worms infest the garden, lay pieces of board about. The worm will take refuge under the boards in the heat of the day, and may then be killed.—*Indian Agriculturist.*

AMONG recent patents is a substitute for caoutchouc, by John J. Hang, of St. Petersburg, Russia. It is prepared by boiling skins and glycerine under pressure, and mixing glycerine and chromate or bichromate of potash with the mass. Ground cork, ox gall, and color may be added.—*Independent Journal.*

MANGROVE BARK.—The bark of the mangrove tree *(Rhizophora mangle)* is coming forward as an agent in tanning. It is crushed, and if necessary soaked in cold water to remove the salt (the trees grow on the tropical coasts), then boiled with water, put under pressure, and the extract evaporated to the consistency of treacle.—*Monthly Prices Current.*

WEEDS.—It is better to prevent weeds by such frequent stirring of the soil as will prevent their development than to let them get established, and then attempt the labor of killing them. This frequent stirring of the soil serves a double purpose. It not only prevents the weeds, but supplies to the crop just the conditions needed to stimulate it to the best development. The surface soil cannot be stirred too often, pro viding it is not stirred so deeply as to interfere with or injure the roots of the growing plant. Frequent shallow stirring is the secret of good crops in the corn field or garden.—*Indian Agriculturist.*

RAINFALL AND WATER CONSERVATION IN AUSTRALIA.—The late disastrous droughts in the central districts of Australia direct our attention to the questions of rainfall and conservation of water. If we gather together the statistics of rainfall for Australia for all the years in which records have been made, and plot them graphically, as I have done in the rainfall maps for the last two years, a very prominent fact appears, namely, it is only a fringe around the great continent—deep in some places, narrow in others, and much serrated in portions—that is blessed with sufficient rainfall to render successful agriculture possible, while over a vast central area the average is so small as to make it a matter of surprise that in such an arid region can be maintained vast flocks of sheep, which return in favourable seasons enormous wealth in the shape of wool. Now, over the regions I am speaking of, the average fall is from 10 in. to 5 in. per annum. This seems to be the maximum that can be expected in the most favourable years, and it is now well-known that favourable years are the fewest. It appears inevitable, therefore, that to avoid disaster and loss flockowners should not be tempted by a year or two, when the rainfall has not only been near the maximum, but also well timed, to increase their flocks beyond their power of maintenance in the drier years which are always found to follow. If we examine the rainfall map we find that between these comparatively arid central regions and the coastal fringe of bountiful rainfall lies an area, in some measure parallel to the coast line, but whose inland margin is very irregular (owing to the physical features of the country), which is shaded to represent an annual fall of from 15in. to 20in. This margin may be assumed to be the limit of our wheat-growing areas.—*Mr. Ellery's Address to the Royal Society of Victoria.*

MR. WOOD-MASON has just sent me his paper (writes Dr. Trimen): there are three very fine plates illustrating the Tea Mite, but no figures of the Tea Bug are given.*

CACAO GROWING IN OLD PADDY LAND.—A planter writes:—"By parcel post I am sending a cacao pod from a tree 2½ years old planted in old paddy land. There are some 40 more on the tree which is of the light red Forestero variety. What think you of it?"—[One of the finest we have ever seen: it measures 10 inches in length, 12½ inches in circumference, and weighs 30 ounces.—ED.]

FERNS.—In some of the streams in the interior of Queensland, among the tropical luxuriance of vegetation, there grows a curious and, when closely examined, very beautiful water fern; it grows so densely that the surface of the water is covered with it, excepting only where the lily spreads its leaves. In colour the fern is, when massed together, a dark crimson, and the contrast between it and the bright green vegetation on the margin of the creek is exceedingly picturesque.—*Australasian.*

OSTRICH FARMING in South Africa has advanced with such strides that the number of tame birds there is estimated to have increased from 80 in 1865 to at least 70,000 in 1884, producing feathers for export of the value of about £600,000. The business is, to all appearance, practically without limits, as the demand for the feathers seems to be an ever increasing one; and the profits, although fluctuating, are usually so large that it would appear to be just the kind of industry to tempt those with sufficient capital whose lot is cast in a country with a semi-tropical climate, and where land is cheap.—*Australasian.*

THE IMMENSE DEPOSITS OF SALTPETRE in Bolivia are well-known both in commercial and agricultural circles. How came they there, and what is their origin? These questions have both been answered by Mr. Sacc, who, in a paper read before the Paris Academy of Sciences, gave a full account of the deposits and their vast extent. He says they will supply the whole of the world with nitrate of potash. They contain over 60 per cent of that salt, associated with more than 30 per cent of borate of soda, better known, perhaps, as borax. Mr. Sacc believes that the saltpetre is nothing more nor less than the result of the decomposition of an enormous deposit of fossil animal remains. Every year is demonstrating how much the present inhabitants of the earth's surface are inhabited to those which preceeded them in one or another of the various geological periods.—*Australasian.*

NORTH BORNEO.—Over two hundred thousand tobacco plants have been put out on the Suan Lamba Estate, and planting is going on as quickly as possible. The Manager expresses his satisfaction with the experiment so far. His Excellency the Governer, accompanied by the Acting Resident, visited the Chinese Hakka settlement at Kudat on August 9th. The gardens were looking exceedingly well, and it was evident that the men never were so happy and prosperous and there was no sickness. It is satisfactory to find that the settlers are planting produce for the China market, instead of growing vegetables only, as at present there is very little sale for the latter, owing to the Chinese who are planting near the settlement growing more than enough for local consumption. Some young Liberian coffee plants were looking very healthy. If these Hakkas will grow ground nuts and other valuable products for export in fair quantity there is no reason why they should not get on well, and form the nucleus of a large agricultural settlement.—*Straits Times.*

---

* At which we also felt disappointed. Mr. Peal's paper and plates are referred to.—ED.

MARKET RATES FOR OLD AND NEW PRODUCTS.

TEA CULTIVATION IN CEYLON.

"THE GOOD TIME COMING"; A WORD OF WARNING.

For many weeks back we have been intending to sound a further note of warning in reference to the reports of tea-planting which reach us from nearly every coffee district in the country. The gradual change which we have watched with pleasure during the past few years has, this season, developed into an activity which in some respects may be termed at once abnormal and unhealthy. We are threatened with a transformation scene in which an expanse of coffee covering hundreds of square miles of country is to be suddenly exhibited to the admiring gaze of all and sundry, uniformly covered with tea. The serrated bright green leaves are to take the place of the dark-green laurel-like vegetation, and proprietors who have been despairing over coffee plantations hopelessly smitten with the dire fungus are, in the shortest possible interval, to be enabled to rejoice in an equal expanse of the future king of Ceylon staples, tea. Considering the local scarcity of capital, it is astonishing to watch the large areas which are being planted over with this new product, and the only parallel we can find to the urgent way in which the work of planting is being carried on in some districts, is in the great rush of 1870-6 into the Dimbula and Maskeliya districts when men used to boast of planting their 500, 700 and even 1,000 acres with coffee in one season. Not once or twice, but very often in the *Observer* of that day did we state openly that such men in place of boasting, ought to be ashamed of themselves; for that it was utterly impossible that any individual planter could do justice even as supervisor or visitor to the planting of so large an area. Far preferable was the system in the old Kandy districts when if an estate manager planted 50 or at most 100 acres in a single season, roading and draining his clearing and doing his task well, he was considered to have got through a heavy bit of work. We need scarcely say that no small proportion of the poor results given by coffee in the high districts—making all allowance for leaf disease—may be traced to hasty work, the use of poor plants which were transferred from nursery to field anyhow and finally to the neglect ensuing on a mad speculative spirit which left purchasers burdened with debt out of all proportion to the crops *in esse* or *in posse*. That we are not exaggerating is proved by the fact that there are individual estates in the young districts, some of them in the poorest corners which, notwithstanding all the experience of disease and short crops of the past seven years, have through strict economy and avoidance of debt, paid their way and left margins to the proprietors which have enabled cinchona and finally tea to be judiciously planted in supercession of portions of the coffee.

Now-a-days the emulation which ten years ago gave no rest to the land until every strip of forest in so many upland districts was cleared away and replaced by the coffee shrub, is prompting a similar widespread supercession of the old staple by the one product, tea. It is in deprecation of any such sweeping process of supercession that we would now offer words of warning to proprietors. The other day we heard of a gentleman in one old district who was the possessor of 800 acres of tea and we could not help remarking that probably in the long-run life would be as well off with half that area, carefully selected and as carefully planted. We went of course a good deal on the fact that acre for acre, tea entails a good deal more responsibility than coffee, and that both in respect of cost of cultivation, expense of preparation, labour supply and supervision, the proprietor of 800 acres of tea must be considered to be as heavily weighted as probably the owner of a coffee plantation with from 1,200 to 1,400 acres in cultivation. Of course when all the conditions referred to have been provided for and when the proprietor is clear that his coffee land is never to do him any good, we have nothing more to say about its supercession save that the motto should be *Festina lente*. We have a strong leaning to the policy attributed to one member of the Stalkart family—long and honorably connected with the Indian tea enterprise—namely the limiting each of his gardens to from 50 to 100 acres and when a manager asked leave to trench on reserves and add to the importance of his charge the answer would be: 'No; cultivate what you have and raise the yield from 6 to 8 maunds and your average price per lb. by 2d, and your salary will then be increased just as much as if you had 150 to 300 acres in your charge in place of 100.' We commend this policy to the serious attention of proprietors in Ceylon. Not once or twice in the past history of planting have we seen the proprietor of a most remunerative hundred acres of coffee, ruined by the hasty and unwise enlargement of his estate—cutting down every stick of reserve irrespective of shelter, lay of land and quality of soil—to an area of two hundred acres. Let the tea-garden proprietor with a moderate amount of capital beware. Far better make full experiment with 50 or at most 100 acres than rush in, because everyone else is doing so, for 200 or 300 acres under tea.

There must on every average estate be patches, if not fields of coffee in better heart than the rest, and these ought to be worth the experiment of being surrounded by tea, protected possibly hereafter from the *hemileia* spores which have in the past spread unchecked over the uninterrupted expanses of coffee. If, as is expected, a steady turn upwards for coffee prices and the crisis in Brazil are drawing near, we may yet see not a few Ceylon proprietors regretting their too hasty supercession of fairly decent coffee by tea.

But there is another and more serious element of risk attending the present "rush" into tea. We refer to the quality of the seed used and on this point we draw attention to two letters in our Correspondence column today. One of these deals with the character of seed locally gathered from young immature trees in some cases, and very properly refers to the lesson learnt from coffee-planting ten years ago, as well as to that from the subsequent rush into cinchona planting. The other writer—a Ceylon planter on a visit to Assam—declares that tea-seed is now being sent to Ceylon from Assam which no Indian planter would look at;—that while Assam planters pay R150 a maund for the privilege of picking the fully ripe seed of the jât they approve, Ceylon importers will pay no more than from R30 to R50 per maund. Such seed is, of course, meant to sell, not to produce good healthy plants; and it is even whispered that seed (absolute trash) has been imported here at a good deal less than thirty rupees per maund. Such importers ought to be shown up; but planters have themselves to blame, for they can well judge from the price that the article sold to them cannot be relied on, and far better to buy fewer maunds of really good seed and be content with a small acreage of reliable tea than to scatter weak plants, the product of poor seed, over a large area. Of course, there will be proprietors now as in 1876 whose chief object in planting will be not to grow heavy crops, and so

secure remunerative returns on capital invested for a series of years, but who plant on the chance of a "boom in tea" in order to sell at the earliest possible date. We have no doubt the day is approaching when there will be a brisk enquiry for tea property in Ceylon. We need only refer to the several intimations in our London Letter today in support of thisview ; but we trust that when the good time does come that capital will be freely available for the purchase of Ceylon tea estates, intending purchasers may be on their guard, to examine and enquire most scrupulously into the history of the tea seed and the plants on the plantations offered to them. Proprietors who heedless of the quality of the seed, or the vigour of the plants they use, are "planting to sell" may however, inflict a very serious injury on their brother planters and on the colony at large. "S." makes rather sweeping inferences from his observation of the coffee leaf disease ; but he is certainly right that coffee trees grown from immature seed fell easy victims and in turn became prolific nurseries of the leaf disease. No readier means of developing serious enemies to the tea-plant can be devised than by covering large areas with weak plants grown from poor tea seed. From this point of view too we do not at all regard with satisfaction the prospect of old coffee districts being transformed into uniform expanses of tea, even if the seed and plants used should be all that could be desired. It was in the diversity of products which was henceforward to rule in our planting districts that one great safeguard against the appearance of another serious plague or epidemic was found. Let all decent fields of coffee be maintained ; let cardamoms or other minor products be tried ; and let everything be done to encourage the planting of estate and road boundaries as well as isolated patches with cinchona, so that we may never again see unbroken expanses covered with one and only one product for many square miles in the hill-country of Ceylon.

We have no fear that our remarks will cast any shadow over really sound and judicious enterprize in the extension of tea cultivation in Ceylon. The experimental stage may be said to be already past. Capital is becomingly increasingly available not only from London, but from Glasgow and Melbourne for needful investment in tea gardens or in the formation of tea properties in Ceylon. Practical planters from India have already proclaimed our tea industry as established generally on a sound basis and visitors of experience "in tea" from "the city" portion of the metropolis express themselves delighted with our prospects. We have just had the report of Mr. Curtis of Darjeeling who after a round of some of our tea districts, leaves tonight by the S. S. "Nepaul." Mr. Curtis travelled up by Hewahatte and Maturatta to Nuwara Eliya, thence down through Lindula to Pundhuloya, back to Dimbula and Dikoya and down through Ambagamuwa and Dolosbaga. The finest teas he saw were made on Loolconduia and Galboda, and he was much pleased with the soil on the latter property as well as on Mariawatte. But he maintains that labour in Darjeeling is far cheaper (at from 2 to 5 annas per day for men of the independent hill tribes, strong hardy Ghoorkas, &c.) than cooly labour in Ceylon and that the returns in crop from choice estates in India have not yet been beaten. The age of gardens in India is counted from the sowing of the seed, and not as in Ceylon from the planting out, making nearly a year's difference. In Darjeeling, tea has given at three years from seed being sown (within two years of planting) 560 lb. per acre over 150 acres. So much for comparison ; but quality even more than yield will have to be studied by the planter who would make tea pay in Ceylon, and it may be a question whether a plantation like Loolcondura averaging four to six maunds per acre per annum, may not in the long run prove the most profitable on account of the uniformly high reputation and splendid prices realized for its teas.

CEYLON UPCOUNTRY PLANTING REPORT.

TEA PLANTS AND INSECTS—TEA CLEARING ALL BEFORE IT—COFFEE AND BLACK BUG—WESTLAND'S SIEVE PLATE—THE RISE IN COFFEE AND ITS VICISSITUDES—PLANTING LITERATURE.

2nd December 1884.

There is something very pathetic in the way planters examine their young tea plants and report at once the presence of any new insect, malformation, or indeed anything out of the common. The fell enemy which ruined the coffee enterprize and brought about so much loss and disappointment was so trifling, so despised at first, and yet in the end so all-powerful for evil, that the attitude of the planter towards anything on tea is natural enough. It is earnestly to be hoped now we have got, after much hunting about, something really suited for Ceylon, and which is likely to do much towards pulling the place round, that this promising product may long be preserved from enemies of any kind, and go on flushing with renewed vigour from day to day.

Everything is going down before tea: coffee, good, bad and indifferent, is mercilessly taken by the head and pulled out; even cardamoms, of which so very much has been said and which have really done wonders in favourable positions, have in some cases been ousted for the new favourite. This last seems passing strange, for when cardamoms pay, they pay well, and, as long as the soil is suitable, and they are healthy—well, of course every man judges for himself.

That coffee should go is no wonder, for I hear more and more deplorable accounts of the ravages of black bug. Its presence on an estate in that intense form, "which blackens every spot," means really sudden death. Leaf-disease which is still with us is a mere flea-bite, as compared to the remorseless gangs of black bug. The former did leave some room for repentance, and gave a chance to cover the ground with something else ere the coffee was altogether worthless, but black bug which has attacked what leaf-disease has spared leaves its victim sucked out and dry—a hideous and depressing sight.

We used to say, that, if leaf-disease would but finish the coffee at once, planters would have the worst, and know what to do. Well this is just what black bug has done. Acres of coffee which at the beginning of this year looked good enough to be able to fight their way until re-inforced by better prices are now only fit to be abandoned or turned out to make room for something else. I make bold to say, that, unless this pest be checked by climatic or other causes, it will altogether put out the old dethroned king and cause his name to be forgotten in the country where he has reigned so long. I am sorry I know of no cure for this enemy. Formerly it would appear in a damp corner or quiet spot, and, if left alone, would go away of its own accord, leaving more or less of its evil effects behind ; but in these days it spreads over acres, climbs any shade trees and blackens the ground all about and refuses to be doctored. Lime, ashes mana grass, &c., have been tried and failed. Probably there may be a cure, although I do not know it. North and immediately to the south of Kandy, the black bug and fungus have done their very worst, and it is to be hoped that it won't travel up to Dimbula and Dikoya or into the Uva district ; for, if so, they have a rough time before them, and can hardly be expected to fare better than the sufferers of today.

Westland's sieve plate is, I hear, doing great things, almost entirely abolishing tails. Except that it lets a good many skins through, it would be perfect; but thin skins can easily be floated off during washing. Had this sieve plate been in the field ten years ago, it would have proved a small fortune to the inventor. As it is, let us hope his ingenuity will not pass unrewarded.

Money is coming to the island for investment in tea. A Glasgow Company is said to have placed at the command of one of our local firms the sum of £50,000 for the furtherance of the tea industry.—PEPPER CORN.

JAVA PLANTING NEWS:

COFFEE LEAF DISEASE ATTRBUTED TO "ERYTHRINA" TREES.

A reporter on plantations in the eastern part of Java mentions that, after all, planters need not be so generally discouraged. As for the tobacco planters, their crops look well, and they have every chance of doing a good business. Regarding coffee-planting, a great deal more is talked about the leaf disease, than is sanctioned by facts; the truth is that the disease was known long ago, for so far back as 1840, I was told that it was nothing new, and that it was caused by planting *dadap* trees between the coffee plants for shade, and my experience since has convinced me that this is the case, for wherever coffee is planted in forest land, or where no *dadap* trees are used for shade, there is no sign of leaf disease. Even the *kina* planters do not seem to be faring badly. In short, planters in general smile and look happy, excepting the poor sugar-lords, who in former times held their heads up proudly; but now they seem much crest-fallen, without any hope of help from the Government.

People say that prices are sure to rise again, but only those who work upon their own capital will be able to stand these bad times. Many a poor sugar planter, who has to pay 9 per cent yearly upon a capital of a couple of hundred thousand guilders, will have to shut up before that time; and Java will lose a great part of its riches.—*Singapore Free Press.* [After all we have heard of the merits of the *erythrina* plants as shade yielders, it is curious to have leaf disease (known so long ago as 1840!) attributed to them. *Kina* is, of course, cinchona.—ED.]

GORE'S TEA SIFTER AND SEPARATOR.

There was a very successful trial of this machine at the godowns of Messrs. Maitland & Co. the other day, quite a number of gentlemen interested in our new staple being present. Fifty pounds of tea were in a period of ten minutes sifted and separated into seven sorts, the speciality being the two separators which eliminated the *flat* broken tea, small and large. The broken pekoe and pekoe were, of course, much improved in appearance by the absence from them of the flat pieces and the dust. Altogether the impression of beholders was in favour of the simplicity of design and easy working of the machine, the cost of which is moderate. As our readers are aware, the separators can be used for hand work in stores where the complete machine may not be in use, and to the value of those separators, Mr. Armstrong has borne strong testimony.

Mr. Gore has written to us as follows:—

"After weighing up the teas sifted today, I have the pleasure to inform you that the approximate percentages are as follows:—Dust, 4 per cent; Souchong, 25 per cent; Pekoe Souchong, 34 per cent; Pekoe, 15 per cent; Broken Pekoe, 17 per cent; Broken Tea, 5 per cent. It must be borne in mind that the sample of Bulk Tea which I had sent from the estate was very inferior, having much coarse leaf in it."

AN ODD USE FOR RUBBER.—A proposal was made in one of the journals half-a-century ago, when the Indiarubber industry was still in its infancy, "to coat the bodies of the dead with Indiarubber, which being quite impervious to damp and air must preserve the body as if preserved in cloths after the manner of the Egyptians." This was recommended in order "to obviate the enormous expense to which individuals are frequently put in the interment of their deceased friends, and will preserve the body as effectually as if laid in a leathern coffin." How this is to be effected is thus described:—"The body, being laid out, is to be brushed over with a solution of Indiarubber five or six times, until it is of a sufficient thickness; this done, nothing else remains but putting it in a light wooden coffin and interring it."—*Indiarubber and Gutta-percha Journal.*

AN INDIAN TEA PLANTER of experience, Mr. Curtis of Darjeeling, now on a visit to Ceylon, we learn is delighted with what he has seen of tea in the Central Province. The flush on the trees at a high elevation greatly pleased him and also the size of bushes which he said beat in some cases anything he has ever seen in India. The quality of the teas has also highly delighted Mr. Curtis.

TEA PROPERTIES.—The enquiry after old estates and land available for tea-planting has become so brisk, that one gentleman, whose advertisement appears elsewhere, is anxious to meet the views of his constituents both in the island and at home by making up a list of all the properties that are for sale. "It really seems" says a correspondent, "as if Ceylon were entering upon an era of *real* prosperity, and I am sure we all hope it may be so."

TEA IN THE KANDY DISTRICT.—What do you think of the enclosed tea leaf for Kandy side growth? It has been hinted that we are a little dry for tea, but if we can grow 9¾ inch leaves to start with, what will we not do afterwards.—*Cor.* [The specimen is a splendid one, and, if it be a type of what can be grown, all we can say is that our correspondent may go ahead and prosper. Our correspondent adds:—"As the Kandy side of the country is spoken of by some as rather dry for tea, I think it is well proprietors should know what *is growing.*"—ED.]

TEAS AT THE HEALTH EXHIBITION.—On the descriptions and qualities of the tea and coffee exhibited, a somewhat lengthy paper might be written. The specimens of coffee and tea shown are very numerous, but, unfortunately, there are very few specimens of China tea included in them, by far the greater part being India and Ceylon teas. The large increase in the importation of India and Ceylon teas, and the falling off in China teas, point to the fact that the colonial teas are fast rising in public favour, and this appreciation of their good qualities is deserved on account of their strength and flavour, and their use in the blending of teas for home consumption. Some of them, such as the Darjiling, can be used alone; but they generally pass into consumption as blended tea. In the Chinese court only two specimens of tea are exhibited, but they are not for competition. They are sun dried, and contain flowers of the tea plant. The flavour of the tea in liquor is exquisite, but its character, appearance, and price preclude it from being a commercial tea, although it is greatly appreciated in China, and considered of the highest quality.—"*Report on Beverages*" *at the Health Exhibition by Mr. R. Banister, F.L.C., F.C.S.*

HARD TIMES.—A Demerara contemporary says:—"Wherever we turn about in the colony the cry proceeds from each and all—"The hard times." This is no imaginary evil, for it affects the rich and poor alike, the capitalist and the labourer, the adventurer and the son of the soil, and it is high time that the question should be approached so that something might be done to stay the tide of poverty and want which is overrunning the colony. We have depended entirely on one industry—the sugar production—to meet and satisfy the wants of all. As long as things went smoothly there was no need to complain, but West Indian sugar has had to compete in the markets of the world with a great and mighty opponent—the beet. Slave-grown, bounty-fed sugars have displaced our production, and we have been compelled to suffer an ignominious defeat, only cherished by the hope that the fields of beet which are subject to inundations may yet give way, and so afford us a partial victory. In the absence of this disaster to our opponent the proprietors of the West Indian sugar estates have been shortening pay, restricting employment, and destroying the condition of the colonies by amalgamation."—*Colonies and India.*

A MODEL PROVINCE FOR A VARIETY OF PRODUCTS AND INDUSTRIES is that of Pernambuco, Brazil, which is stated to have 2,000 sugar making establishments, producing 170,000 tons of sugar annually. The culture of cotton is augmenting. Of coffee, whose culture was commenced in 1876 there are 500,000 trees; and of cacao, also recently introduced, there are 200,0 0 trees and the culture is progressive. Wheat growing has been initiated successfully and two crops per annum can be obtained. Tobacco is exported in cigarettes and twist. The carnauba palm wax is exported into England and Germany, but the manufacture of candles from it has been commenced in the province. Besides various excellent fibres, the province possesses a large number of cinnamon trees, yielding well, but the product is not exported. The province has one cotton factory, several soap factories, tanneries, &c.—*South American Journal.*

SAMARANG, 25th October.—A German traveller recently saw fit to gladden us by the information that he had detected a cinchona leaf disease in Java during a three weeks stay in the Preanger Regencies, and it speaks much for his sharpness of eyesight that, within such a short time, he noticed that there was every prospect of the disease becoming as destructive in almost all cinchona plantations as the *Hemileia vastatrix* is in coffee estates, though the managers concerned were wholly unaware of its existence, which the German traveller was destined to reveal to them, not at once, for that would perhaps have had a disturbing influence on his travelling plans, but later on in a Batavia journal. Several Cinchona plantation managers made inquiries in consequence on different estates finding that neither on trees in prepared ground nor among seedlings in the nurseries was there any sign bearing the character of new epidemic disease. The spots always noticeable on the leaves of almost every variety of cinchona as foretokens of their periodical fall had been taken by the German traveller for symptoms of disease, whereby he gave proof of particular greenness in the domain of Cinchona cultivation. His rash and groundless assertion might notwithstanding, have done much harm, had not the abovementioned managers come forward with their positive statement grounded on thorough inquiry that there was nothing in it—*Locomotief.*

SUGAR AND COFFEE PLANTING IN JAVA have fallen on evil days to judge from the following extracts which we take from the *Straits Times.* We fear the anticipation of an early disappearance of the leaf-disease in coffee is not likely to be realized:—

By last advices, in East Java, owing to the low quotations ruling for sugar cane, planting has been relinquished on several estates, while, on others, employes have been discharged in great numbers to cut down expenses. A correspondent of the *Java Bode* asserts that leaf-disease has wrought such fearful havoc on coffee estates in Mid Java that, on plantations from which, last year, the shipments of coffee amounted respectively to 11,000, 3,300 and 2.200 piculs, the crop this year barely reached 1 000, 170 and 150 piculs. With results thus set forth:—It is universally acknowledged that leaf-disease is of a temporary nature and that the growing crops can only be saved from it by heavy manuring. For this purpose, a large capital is required; but, instead of planters meeting with facilities in getting it, credit of any kind is refused them perhaps in consequence of the heavy losses experienced in sugar, whereby they are compelled to sell off their estates. The latter are generally bought by the firms that advanced the working capital, and they are now sure of being within 3 or 4 years, when the disease shall have ceased, in possession of several plantations with which formerly only consignment contracts were concluded. It needs no proof that in this way, the outlook for the planters is gloomy indeed. We know the names of several persons who, after having grown coffee for upwards of 30 years, have, along with their large families, become destitute. Cinchona and tea planters in West Java have every reason in that case to be glad that they are carrying on these kinds of cultivation, though the yield from their cinchona estates is still scanty and though the price of tea is no longer what it was three years ago.—*Java Bode,* 3rd Nov.

A PROPOSAL is on foot to start a Dairy Farm Company, Limited, at Darjiling, with a capital of R50,000 in 5,000 shares of R10 each. The object of the Company is said to be to provide Darjiling with dairy produce, vegetables and provisions, from a farm which is to be established on the most modern principles in the immediate proximity of Darjiling. A plot of 1,800 acres has already been secured on which it is proposed to build a Manager's House, the necessary farm buildings, dairies, &c. The whole will be under a European Manager Director, who is stated to have had eighteen years' experience in dairy farming in Lincolnshire Sussex.—*Madras Times.*

PLANTING IN PERAK.—A correspondent writes to us from Kwala Kangsa, Perak, as follows:—"A six foot road is now being made from Kwala Kangsa to Patani, which will open a very fine tin and agricultural country, and bring back many Malays who have, some time ago, moved on and on. Using this road as far as Engor, and crossing the Perak river in a boat, a foot-passenger from Kwala Kangsa can easily reach Salah—the coming tin district—within three hours. Another road is also being made from here to Ulu Bernam, which, when finished, will complete the route from Perak to Malacca *via* Selangor and Sungei Ujong. Both these roads are now in progress, and we expect to see them nearly finished in six months, or a little more. Another road—this one a cart-road—is being made from Thaipeng through a great tin-mining district—Selama. This road is only just commenced, and will, most likely, take some time to finish, as it is to be some thirty miles long. The railway is not yet open to the public, but we hope to see it at work before very long. During the last three months, several men have come from Ceylon, and turned from coffee to tin. Let us hope they may have better success than the other European Companies up to date. The Government Coffee Plantations are doing very well, and a well-knowu Ceylon planter has just arrived and taken the management of them. That Perak will eventually become a great coffee-producing country, I quite believe, as do many others. The town, as it is now called, of Kwala Kangsa is going ahead with brick shops, and is becoming quite a large and important place. Some months ago, there were only three Europeans living here, and there are now ten, which speaks well for the place. This is a great field for sportsmen, and the wonder is that more of them do not come over from Singapore."—*Singapore Free Press.*

CAN IT BE TRUE?—The *Indian Agriculturist* states:—Our readers have become pretty familiar with the tree known as the *eucalyptus globulus,* an indigenous tree of Australia, the product of which has been so largely utilized in the arts and manufactures. We now hear that a process has been invented in America for the manufacture of a preparation of the gum of the *eucalyptus globulus,* which promises to be of invaluable help to shipowners and others interested in the shipping interest. It has the effect of removing thoroughly the scales which form in engine boilers, and prevent rust and pitting. A Company has been formed and a factory erected at Piedmont, with a capacity of 1,000 gallons a day and employing 30 men. The result of the introduction of this preparation has been so great, as to create an immense demand for it both in America and Europe to an extent of which the Company could hardly form an idea when it started the concern. The effect of this preparation in preventing the pitting and corrosion of boilers will, it is expected, extend the period of their usefulness 100 or 150 per cent, and at the same time effect a great saving in fuel, as scale is a non-conductor of heat, and therefore more fuel is required to generate steam in old boilers than in clean new ones. This may, if all that is claimed be true, tend to decrease the manufacture of boilers, but, on the other hand, it will lessen the liability of explosions. The Company have also embarked in the distillation of the essential oils of the *eucalyptus globulus,* which are extensively used for medical purposes, and which have heretofore been supplied in Australia, it being found that the oils can be produced at a profit. With this object in view, the Company propose to set out extensive forests of *eucalyptus* trees, in order to have at its command a sufficient supply of leaves, the portion of the tree consumed in the manufacture of the oils.

Correspondence.

To the Editor of the "Ceylon Observer."

TEA JÂT AND THE QUESTION OF HYBRIDS.

Assam, 1st Nov. 1884.

DEAR SIR,—As so much attention is now being paid to tea, any information about its cultivation and jât will, no doubt, be of interest to your readers. I will confine my remarks at present to jât. During my visit to Assam, I have paid particular attention to jât in order to find out which is likely to be most suited for Ceylon. After careful consideration and repeated proofs, I have come to the conclusion that "Assam hybrid" is a misnomer, and that there is no such thing as a hybrid in tea. This will, no doubt, be considered a rash statement, and utterly absurd and not worth listening to; but I have no doubt whatever on the point myself, and I will explain how I have arrived at the conclusion. The popular idea is that Assam indigenous is one plant, and China another, and that these two species having been planted in close proximity have hybridized, and that the result is a hybrid called Assam hybrid. We must not forget that hybrids are extremely rare things in nature, and where hybridizing does take place, it is by artificial means. Bees and insects of various kinds are said to carry the pollen from one flower to another, but who taught them to carry out their work of hybridizing so systematically and carry the pollen from the China to the Assam? Why not carry from the Assam to the China? In the former case, the Assam crossed by the China, results in "Assam hybrid," and in the latter it would be "China hybrid." China hybrid is a term used, but it is not got in this way—it is used to indicate a low jât of plant. Is it not natural to suppose, that, if the Assam deteriorates by being crossed by China, the China would be improved by being crossed by the Assam? This, however, is not the case: no improved jât is ever the result; therefore it is no hybrid. I have had opportunities of tracing the seed from the indigenous trees growing in the jungle down to the lowest jât. It runs in a downward scale. Seed from the indigenous produces a fine plant which we'll call No. 1. Seed from No. 1 produces a plant slightly inferior, which is No. 2. No. 2 produces a plant inferior to it again, and so on until you get down to a jât of the lowest description. This to me is perfectly clear as I have traced them and find no difficulty in discovering what they are; that is under ordinary circumstances. Of course, there are places, which from want of cultivation, unsuitable soil or some other cause show a jât which might be anything. Assam planters do not admit that the plant they are growing is not a hybrid, but I think most of them are cognizant of the fact that the plant does deteriorate and that seed from one jât always turns out an inferior jât to the parent. The question then to decide is, which of the different grades of plant is the one to grow. Having settled that, secure seed not from the jât of plant you want, but from the jât above it which produced that plant.

The indigenous plant is generally supposed to be too delicate and unsuitable for Ceylon, and that a lower jât is the thing to grow. I cannot myself see how this conclusion was arrived at. The indigenous plant is not found on the plains of Assam, but on the hills, and I could mention several estates in Dimbula with very much the same soil and lay of land as where this plant is flourishing. The elevation is not so much of course as on some of the Ceylon hills, but I don't suppose the plant would object to grow at a higher elevation any more than it does at a lower. The soil on the hills is different from the stiff soil on the plains, just as different as the soil on the Maskeliya flats is from the soil at Avisawella. Ceylon soil on the hills resembles the soil of the hills to which the Assam plant is indigenous much more than the soil on the Assam plains. The jâts once or twice removed from the indigenous are considered quite as good yielding jâts, but anything below that no one would now think of planting. Ceylon men will regret the way they have gone about getting seed by and bye, and they won't find out their mistake until they find that the flushing powers of their bushes are very much less than estates which have got a better jât. The difference between a good jât and a bad one is the difference between profit and loss. A large quantity of Indian seed sent to Ceylon is not worth the carriage. No man in Assam would think of putting it out, although he got it for nothing. Orders are sent up from Ceylon for *hybrid* seed at R30 a maund, and *hybrid seed* is supplied at this rate. No complaints are made about jât or class of plant—if 70 to 80 per cent is found good in Colombo, the Ceylon planter takes his seed and looks happy.

How different it is with an Assam man opening out a new garden. He pays R150 a maund for his seed, sends a man to the garden to see it picked, has it tested, packed after his own instructions and taken away by his own man and pays all packing charges and transport. I had an opportunity of seeing this operation carried out and got the wrinkles about testing seed. Has this ever been done with seed sent to Ceylon? If it has, I have not heard of it. Ceylon men must recollect that no blame can be attached to Assam men for sending them a bad jât: they know perfectly well that good seed sells from R100 to R150 a maund, and yet they are satisfied with seed costing R30. If the Assam men charged the high price and supplied a bad jât of seed, then they would be to blame, but as far as I can see they are perfectly straight about it. They sell seed from R20 to R200 a maund, and Ceylon men prefer to take the cheapest. When good seed is offered to Colombo firms, they say: "*No*, we can get seed cheaper." My advice to Ceylon men who are going in for tea is, get as good a jât as you can—(and this can be got by paying for it), it will flush better, is much more easily managed, withstands red spider, *Helopeltis*, green fly and all the other pests far better than the low jâts.—Yours faithfully, R. L.

[With all deference to this writer, we take it that the question of hybrids having resulted from the contiguity of the Assam and China teas, is no more doubtful than the question of cinchona hybrids. We should not wish to found any conclusion on our own experience, but certainly between 5,000 to 6,000 feet, while the seed we got as best hybrid jât has flourished, what was sent to us as indigenous (both from the Assam Company), has hung back.—ED.

THE WANT OF CARE IN SELECTING TEA SEED.

DEAR SIR,—Your able article on tea cultivation in a recent paper brings forcibly before me a subject upon which I have felt very strongly during the last eighteen months, viz, the want of care in gathering and selecting tea seed and the urgent necessity there is for each one to endeavour to strengthen by using only good seed rather than by filling nurseries with inferior seed to weaken the naturally vigorous plant.

I have always held to the opinion that *Hemileia vastatrix* was in the island years before it was discovered on coffee and that the disease was accelerated by the reckless planting of plants and stumps collected from old weedy estates, many of them grown from immature coffee; others hacked and denuded of bark by mamoty-weeding. In fact so great was the hurry to plant up estates between 1866 and 1876 that any-

thing in the shape of a coffee plant was eagerly bought up with the result that the disease on emerging from its habitat found a genial home on these unhealthy plants and so spread with rapid strides till strong and healthy trees were unable to resist the repeated attacks to which they were subjected.

I also hold that the failure in cinchona is mainly attributable to the same cause, bad seed and plants. During the first 12 years that cinchona was grown in Ceylon, canker was scarcely known and did little or no apparent harm; but in the four years subsequent to 1878 high prices of bark and short coffee crops induced a rush into that product, and so great was the demand for seed, especially officinalis, that it was gathered from healthy, sickly and dying trees in the most indiscriminate manner, the sequel being that not more than 5 per cent had an existence of two years.

I would, therefore, warn those who in their anxiety to plant large areas with tea have gathered and are still gathering seed from two and three year old plants, of putting out plants from seed which according to all natural laws cannot produce healthy vigorous trees and which (as in the case of coffee and cinchona) may prove propagating-beds for whatever disease or blight the tea plant may in the future be afflicted by in the country. Would that your remark "Once bitten twice shy" were universally adhered to,

S.

TEA AND ITS PESTS.

Mahadova, Lunugala, 24th Nov. 1884.

DEAR SIR,—I forward by today's post some tea leaves which ———— has just brought to me to see from his tea nurseries on ————. The disease looks like gall, but I cannot discover the eggs or marks of any insect, and the pekoe tips and immature leaf are principally affected. The excrescence bas a very bitter taste like the tea-seed proper, and the appearance of some of the specimens is as though the plant was uncertain whether to produce leaf or seed.—I remain, yours faithfully,

A. T. KARSLAKE.

[We referred the leaves to Dr. Trimen, who writes:—"Mr. Karslake sent me a packet of tea-leaves similar to those sent you. I replied to his queries pretty fully but have kept no copy of my letter. No doubt the leaves show the work of a gall-fly, but the tumours are too recently formed for the grubs to be hatched yet. A somewhat similar gall is extremely common on the leaves of jambu."—ED]

THE FIBRE FROM THE SHOEFLOWER HIBISCUS.

Kadienlena Estate, Kotmale, 29th Nov. 1884.

DEAR SIR,—You are quite right: the fibre was the produce of the shoeflower (*Hibiscus Rosasinensis*) and, if you have never tried it, I am sure you would be surprized at the large quantity contained on a single stalk. I have thought of it for a long time, as the coolies on a Sunday used to come and cut a few stalks to bind their firewood.

At the price you mention £20 to £25 per ton, I think it would leave a good margin for profit, as it grows very freely. In taking off the bark I have noticed the different degrees of quality: the inner bark being the finest. A person could soon find out at what age it would be most profitable to cut the stems. But we want a machine to turn out clean fibre in payable quantities.

Thanking you for your information, I remain, yours faithfully,

JAMES GRAY.

[The sample sent to us is particularly strong and promising.—ED.]

ALOE FIBRE AND THE PATENT FIBRE MACHINE.

Matale, 2nd Dec. 1884.

DEAR SIR,—Can you kindly inform me whether any experiments have been made on aloe leaves with "Death & Ellwood"'s fibre extracting machine, recently so favourably reported on from Madras and Calcutta? and, if so, with what result? Have you any idea of the cost of the machines? and can you give me the address of any agent from whom I could obtain information on the subject?—Yours faithfully,

ALOE FIBRE.

[Messrs. Clark, Spence & Co, Galle, are Agents for the General Fibre Company—see advertisement in the *T. A.*—who own Death & Ellwood's machines. These have done good work with aloe fibre in Southern India. —ED.]

UTILIZATION OF SOLAR HEAT.—Under this heading a correspondent of the *Pioneer* writes:—The planting of trees cannot be carried out in all parts of the country, nor in many would it be desirable; but that it should be perfectly feasible for an Indian planter to erect an instrument which, by means of energy at present running to waste, could be employed in raising water from deep wells for irrigation purposes is an advance on "the old method of planting trees and burning the timber" which would be patent to most people.

LIFTING AND ROOT-PRUNING FRUIT TREES.—Root-pruning can be safely resorted to where it would be most unwise and unsafe to have recourse to lifting, viz., with strong vigorous trees of old standing. In such cases the only means of bringing about fruitfulness is by root-pruning pure and simple, forming a trench at a reasonable distance from the bole, say 4 or 5 feet, and severing all thick roots which come in the way. With very old trees, and to be on the safe side, the work ought to be done gradually, doing half way round the tree one year and the remaining half the following year. In digging the trench a depth of from 2 to 3 feet will be found to be quite sufficient. But the operation does not end here; something in the shape of undermining must be done in order to find out if there is a tap-root, which must be severed. Having cut through all thick roots, the only remaining work to be done is to pare off all jagged ends and bruised roots with a sharp knife, and fill in with soil, treading it down as the work proceeds, finishing off with a mulching of half-decayed stable manure and a good watering to settle the soil about the roots.—*Journal of Horticulture.*

THE FUTURE OF TEA.—The *N. China Herald* in reviewing statistics of the Indian tea-planting industry is rather hard on what are called "high-flown prophetical utterances." Our contemporary ought to look back over the history of our Ceylon enterprize as some justification for the sanguine estimates of the future:—"A Ceylon contemporary writing upon the Assam report, says that there are no doubt estates which yield 400, 500 and even 600 pounds of tea an acre, but these few and far between, and for a general average 300 pounds is rather above than below the mark. And it goes on to predict that before long Ceylon will leave China far behind as to quality, and run As am a close race as to quantity. That we shall see when we shall see it. It is rather amusing to read the high flown prophetical utterances of the Indian and Ceylon papers regarding the future of the tea trade, and taking these with the exciting annual competitors at Hankow and Foochow, it really seems as if growing tea and dealing in it, proves that its description, as that which does not intoxicate, was founded on want of experience of the trade in all its branches."

SILK COTTON OR "KAPOK" as an article of commerce and export is gradually developing itself. More than one firm of European merchants have made large shipments of the article to Australia where there is a constant and growing demand for the article. The kapok tree from the pods of which the cotton is taken grows wild in many parts of Ceylon, butI saw a vast number of them in the Matale district forming as it were the hedgerow or boundary of coffee estates. These ought to yield an abundant crop of cotton. In other parts of the country where there are waste grounds available the tree will grow with equal luxuriance. It is a pity that in this and other respects those persons who own many broad acres do not set an example for others. What a splendid park would be a thousand acres all planted with this magnificent tree! The tree does not give any trouble at all. If only planted and protected from cattle it grows by itself, and it is rarely attacked by insects, grub or other pests. When the pods attain maturity, the trees are invaded by the flying-foxes, which feed perhaps on the berries. In Jaffna when the Illuppai is in blossom or bearing, is the season for shooting flying-fox, a very exciting sport amongst the villagers. I have not seen the flying-fox so plentiful here, but, at any rate, they are easily dealt with if the trees require to be protected from their ravages. The boundaries of large estates may be planted with these trees. They are very graceful in appearance, not spreading out to any large extent, but growing to a great height like a splendid column.—*Cor.*

NEW PRODUCTS IN THE WYNAAD, 20th Nov. 1884.—The curious difference in the quantity and quality of the crop, on estates in the same neighbourhood, is becoming very conspicuous; and those which are especially heavily laden are mostly suffering very considerably from the effects of the fearful wave of leaf-disease which swept over Wynaad a few months ago. Otherwise, our places are, as a rule, looking wonderfully well; the cinchona plantings are especially prosperous, promising us great things, and indeed we require some such sort of substantial comfort to help us along in these depressing times. Tobacco is the latest fashion: those who believe in it are exceedingly enthusiastic about its prospects. There can be no doubt of the fact that such small experiments as have been already attempted promise exceedingly well. The tobacco "grows like a weed." The preparation is the principal difficulty, and it is proposed to obviate this by getting up experienced workmen, when sufficient leaf has been grown to make such a plan feasible. It is also proposed that the tobacco grown here should be prepared only "in the rough" for native consumption until the quality of it is more established. I hear that a small field lately planted, on property belonging to Messrs. Arbuthnot & Co., is promising remarkably well, and that it is likely that it will in consequence be much more extensively cultivated on the same estate. *Tea* and *Cardamoms* also look A. 1. The flushes on the former seem to be incessant, and, to judge by the amount of leaf brought in every evening off one estate alone, it ought to be a paying production. The wonder with regard to cardamoms seems to me, why they have never been extensively planted before. It has apparently been an illustration of the old proverb that "necessity is the mother of invention." In the good old days, when King Coffee reigned paramount, it never seemed to occur to us that we had any other strings to our bows; now, unfortunately, we have all the doubts and penalties of mere experimentalizing before us—and at a time when few of us are in a position to risk failures.—*Madras Times.*

THE TOMATO FUNGUS.—Mr. Berkeley writes:—"Amongst the numerous points of interest connected with the Peronospora of the Potato disease there is one which has not been noticed, as far as I know at present, and I recommend it to the acute observation of Mr. Plowright. I mean the mode of its attack on Tomatos. It does not seem to affect the foliage, at least I have never observed it to do so, but is confined to the fruit, which if cut across soon developes the Peronospora in perfection. It is almost impossible in some districts to cultivate Tomatos successfully in the open ground; and this year, which has been peculiarly favourable to their growth, the disease is as bad as ever. I should be very curious to ascertain how the Peronospora attacks the fruit, and in what stage; and now that Tomatos are so general an article of cultivation, it is a matter of some importance. I do not recollect some seventy years ago that the Tomatos were similarly affected. They were not so much grown then, for they were thought to be unwholesome, and even to induce a particular form of disease; and I recollect some hundreds being thrown out of the garden, though the fruit was in high perfection and in a perfectly healthy condition. This, of course, was many years before the Potato disease was known, and consequently before the introduction of the Peronospora, for I am talking of years previous to 1817.—*Gardeners' Chronicle.*

NEW METHOD OF PRESERVING GRAPES.—A Paris horticultural journal gives a new process for preserving grapes fresh for several months that is worth trying. It is an improvement on the process now extensively employed in France, by which the stems are immersed in bottles of water to prevent shrivelling. The inventor of the process is a nurseryman of Villiers. He describes it as follows:—"Toward the end of October I cut the shoot with the clusters attached, sharpen the lower end to a point and stick it into a potato. I spread the bunches out on straw or dry hay, so that they shall not touch each other. Thus prepared, these shoots keep quite as well as if the shoots with the bunches attached were inserted in bottles filled with water." It is probably essential that the grapes be placed in a dry, cool room.—*Public Opinion.* [Might not grapes be brought over from Western Australia quite fresh by this process.—ED.]

SEED TIME AND LIGHT.—It has long been known that light exercised an influence upon the germination of seeds but it has recently been shown by Professor Wollny that the light rays of different refrangibility produce different effects. In white and yellow light, much greater development takes place than in violet light, or in the dark. This difference increases with that of temperature. Professor Wollny believes that this is due to the actual transformation of light into heat. The production of substances which cause osmose in seedlings growing in white or yellow light is favourable to germination by bringing about increased root-pressure. Seeds which possess only a small amount of reserve food-material germinate better in light than darkness. Light causes not only the penetration of roots into the soil, but the formation of copious roots as well. It is thought that the intermittent heat of day and night must thus be favourable to the germination of seeds.

"QUARTERLY SALES OF CINNAMON" constituted the great reform and the panacea for a falling Cinnamon market in the estimation of the Ceylon producers some time ago and an agitation was set on foot to force the hands of the London brokers and dealers. Monthly sales were at last arranged for and these have now been in operation for some time; but alas! so far from benefitting the producer, we are distinctly told by reliable authorities that they are less favourable to his interest than the old quarterly arrangement. For instance, here is what the well-known firm of Messrs. Forbes, Forbes & Co. wrote to one of their constituents here under date, London, October 29th :—

CINNAMON.—The downward progress in values continues, and it would appear to be in a great measure due to the persistent manner in which this spice has been so frequently forced upon the market for many months past: such, at least, is the openly expressed opinion of the trade, and we can only regret that Ceylon shippers, who have held aloof from the dispute so long agitating the market, have had equally to suffer loss with the promoters of the change. The usual August sales went off with spirit at advanced rates, but the sales at the end of September showed a decline generally of 1d to 1½d per lb. On the 27th instant 1,540 bales offered, and, as anticipated, met a dragging demand from the limited number of buyers present. With some difficulty, only 600 bales sold at a further reduction in price on the whole. The few "fine" lots realized about steady rates, but "common" to "medium" kinds, of which the bulk consisted, sold irregularly at a further decline of about 1d to 1½d per lb. on *September* sale prices. 100 bales "unworked" elicited no bids. Of 419 bags chips, 250 bags sold at 2⅝d per lb. The usual sales will be held on November 24th or December 1st. Stock 5,565 bales against 5,310 bales in 1883, 6,614 bales in 1882, 7,393 bales in 1881.

COFFEE PREPARATION.—"Westland's Improved Sieve Plate" is going to be a success according to the following testimonial from the first outside planter who has used it :—

Norwood, Dikoya, 22nd Nov. 1884.

Dear Sir,—Your sieve plate is a great success, and I only wish I had got it sooner. Almost every planter in this district has been looking at the plate, and I have no doubt numerous orders will follow. Our manager has ordered all his superintendents to substitute new improved plates on my recommendation. (Signed) KEITH ROLLO.

To James Westland, Esq.

CASTOR BEANS have decreased in area in Kansas from 1883 about twenty per cent and the crop is below the condition of one year ago ten per cent. The counties having 1,000 acres and over in castor beans are: Crawford, Franklin, Labette and Neosho. The average yield per acre in 1883 was ten bushels, while the prospects for this year indicate less than nine bushels per acre.—*Independent Journal.*

VIRGINIA CORN BREAD.—One quart of white corn meal, one teaspoonful of salt, two eggs and a dessert spoonful of butter. Scald the meal, thoroughly with boiling water. Then add the butter and eggs (well beaten), and lastly a half-pint of milk. If this does not make the batter thin add more milk, for this is a soft-bread, requiring, a spoon in serving. Bake twenty minutes in a very hot oven.—*American Agriculturist.*

THE PROTECTION OF CARDAMOMS.—SIR,—Anent your correspondent "Naicker's" enquiry, regarding the protection of cardamoms, I have the pleasure to intimate that the crop is gathered up before it is fully ripe, as it is apt to be eaten up by insects; besides, the capsules if ripe, split in storing and drying. A pit is dug, which is lined with leaves or straw, and the capsules being picked, are thrown into it. The cardamoms are then dried in the sun, on mats, for four days.—A.—*Madras Mail.*

The Dutch used to have all this nutmeg trade, as they owned the Banda Islands and conquered all the traders and destroyed the trees. To keep the price up they once burned three piles of nutmegs, each of which was said to be "as big as a church." Nature did not sympathize with such meanness. The nutmeg-pigeon, found in all the Indian islands, did for the world what the Dutch had determined should not be done—carried those nuts, which are their food, into all the surrounding countries, and trees grew again, and the world had the benefit.—*Independent Journal.*

SUBSTITUTE FOR MATCHES.—Countless accidents, as every one knows, arise from the use of matches. To obtain light without employing them, and so without danger of setting things on fire, an ingenious contrivance is now used by the watchmen of Paris in all the magazines where explosives or inflammable materials are kept. Any one may easily make a trial of it. Take an oblong vial of the whitest and clearest glass and put into it a piece of phosphorus about the size of a pea. Pour some olive oil heated to the boiling point upon the phosphorus, fill the vial about one-third full and then cork it tightly. To use this novel light remove the cork, allow the air to enter the vial and then recork it. This empty space in the vial will become luminous, and the light obtained is equal to that of a lamp. When the light grows dim its power can be increased by taking out the cork and allowing a fresh supply of air to enter the vial.—*Independent Journal.*

ARTIFICIAL MANURES FOR GRASS.—Can any of your readers recommend a good mixture of artificial manures for top dressing grass on a light loam soil with gravel subsoil? Two or three years ago I tried two experiments on the land. On two plots of old grass I applied lime at the rate of two tons and five tons respectively per acre. No one has been able to detect the slightest difference produced by the lime. On another field, which had been four years under grass, and from which I intended cutting a crop of hay before breaking up with the plough, I applied to a small plot fine bone meal, at the rate of four tons per acre. No one could in this case detect the slightest difference from the rest of the field, either in the hay crop, or the oats, potatoes, and barley which followed. I should however add that the potatoes were planted with a liberal allowance of bones again, along with the rest of the field. From these experiments it would seem that bones and lime are thrown away on grass on this soil, and I should like to try something else.—J. M. W.—*Field.*

HOW NUTMEGS GROW.—Nutmegs grow on little trees which look like small pear trees, and which are generally not over twenty feet high. The flowers are very much like the lily of the valley. They are pale and very fragrant. The nutmeg is the seed of the fruit, and mace is the thin covering over the seed. The fruit is about the size of a peach. When ripe it breaks open and shows a little nut inside. The trees grow on the islands of Asia and tropical America. They bear fruit seventy or eighty years, and have ripe fruit upon them all the season. A tree in Jamaica has over four thousand nutmegs on it every year.

THE culture of the tea-tree in Transcaucasia, which has been recently advocated by Dr. Woeikoff, has already been successfully carried out on a small scale for several years—as we learn from a recent communication of M. Zeidlitz to a Russian newspaper. It was an Englishman, Mr. Marr, who has inhabited Transcaucasia since 1822, who brought to a flourishing state the Crown garden at Ozurghety, and embellished it with a number of lemon, orange, and tea trees, these last numbering more than two hundred. After the Crimean war only twentyfive tea-trees were growing in this garden, and according to Mr. Marr's advice they were transplanted to a private estate at Gora, close to Tchakhataour. Since the estate has changed its proprietor, only two tea-trees have remained, but still they continue every year to flower and to give fruit, and M. Zeidlitz is sure that if the culture be seriously tried it might be successful in the velleys of the Koura and Rion.—*Nature.*

AGRICULTURAL SCIENCE.—Last autumn twelve classes were started in Forfarshire for teaching the scientific principles of agriculture. These classes were attended by about 180 pupils of whom 120 went forward to the examination of the Science and Art Department, and the results are considered most encouraging. The pupils, whose ages varied from twelve to forty, were greatly stimulated by the Dalhousie Bursaries of £5, which under certain conditions are increased to £10 by the Science and Art Department. The idea of these classes originated with Lord Dalhousie, who obtained from the Science and Art Department the services of Mr. Buckmaster, who lectured or held meetings in most of the parishes in Forfarshire, and now that the practicability of the scheme has been demonstrated there is a very generally expressed desire to increase the number of classes. In connection with a few of the classes a plot of land has been secured for the purpose of experiment. Sir John Ogilvy has placed two or three acres on the Baldovan estate at the disposal of the class, and the pupils and others take great interest in what is going on. It is perhaps early to speak of the result of this instruction, but some are of opinion that these classes have already begun to tell on the agriculture of the district. —*Public Opinion.*

RIPENING OF THE WOOD OF FRUIT TREES.—Every gardener of experience knows how important it is that the wood of fruit trees be well ripened, as it is only when in that state that the blossom-buds become fully organised, and if they do not reach that stage it is impossible for them to remain on and set. If they do not do this next spring, it will be entirely owing to the weather then, as never do I before remember so good a promise, for though trees were a little distressed after the great heat of the summer, they have recovered wonderfully since the heavy rain early in September, and are now studded with big fat buds that look almost ready to burst, and these are still being fed by the healthy fresh-looking leaves, many of which are only just changing colour. Truly it has been a beautiful season, and such an one as rarely occurs, and the memory of the oldest inhabitant seems taxed and must go very far back to recall the date of one anything like it. Some persons in their anxiety to hasten maturity sweep off the foliage; but in my opinion that does much more harm than good, as trees part with it readily enough when the buds no longer require its aid, and frost often robs them full soon. To anticipate the natural fall and strip them is ill-directed zeal, and few who denude their trees would be found doing the same to their Vines, but if it is right in the one case it must be in the other. Instead of brushing the leaves off, it is far better to thin out the wood directly the fruit is gathered, when most of the pruning may be done with satisfactory results to the shoots left, as they then get full exposure, and assume that hard, nutty-brown hue we all like to see.—J. S.—*Gardeners' Chronicle.*

CURING SUMACH.

The following is the Virginian method of gathering and curing sumach for market:—The leaves are stripped by hand from the branches of the bushes where they stand, and thrown into baskets. Care must be taken to keep the leaves clear of twigs litter, and the bunches of sumach seed, which are often abundant upon the bushes the latter part of summer.

The filled baskets are emptied into a cart or wagon, which stands ready, and the leaves are taken at once to the curing yard, where they are spread upon low scaffolds to dry. The green leaves should not remain in bulk any length of time. Nothing begins to heat sooner than green sumach leaves, even when in very small heaps. A basketful will acquire a sensible heat in one hour. It is therefore necessary to dry them quickly, to prevent heating and spoiling.

Spread the leaves thinly on the scaffold. By the second day, if the weather is clear and hot, the contents of two scaffolds may be placed on one, thus providing room for more fresh leaves. The leaves will cure enough to house in bulk in three days of fair weather. It is best to have the scaffolds under trees or other objects to shade the sumach while curing, as thus a finer color is imparted to it.

It takes several pounds of the green leaves to make one when cured, and a person must be nimble if he gathers enough in a day to make a hundred pounds of dried sumach. The price paid for cured leaves here, does not make the business very profitable. We were paid one dollar and a quarter per hundred pounds last year, shipping it in bags eighty miles to Richmond. The cost of bags, freight, cartage, etc., is to be deducted from the selling price named. The curing season coming, however, at a comparatively leisure time, there is some margin for profit, and our country people may well turn an honest penny at this small industry. The plant grows wild, and requires no cultivation or care. The collector here only cures the leaves, and sells them thus to the grinders, who have their mills and warehouses in the cities of Petersburg, Richmond, etc. If collectors had the means for pressing the cured leaves into bales of small compass, so as to save room in transportation, farmers at a distance from the markets could well afford to collect and cure sumach leaves for shipment. Those having cotton or hay presses should use them to advantage. VIRGINIAN.—*American Agriculturist.*

FIG CULTIVATION IN SICILY.

There are several varieties of the fig tree in Sicily, some yielding a large, others a small fruit, and this fruit varies in its degree of sweetness, also in colour from white to black. The fruit of some varieties ripens sooner than that of others. The trees grow equally well in poor and rich soil, and bear abundantly when planted on the mountain side and in the valleys. Consul Woodcock, of Catania, says that the favourite varieties of Sicilian figs are the *Sangiovannaro*, the *Sottano*, the *Melinciano*, and the *Ottalo*. The *Ottalo* has smooth leaves, the peduncle of the flower and fruit is longer and the fruit is sweeter than that of the other varieties. The *Ottalo* fig is considered to be the best for drying. The fig is propagated from the suckers that spring up from the roots, cuttings from the tree being also used, and these are set in the months of February and March. In orchards the distance maintained between the trees is about twenty-six feet. The fig is long-lived, as it is constantly being renewed by shoots that spring up from the roots taking the place of the main trunk when it becomes old and decayed. The soil is worked in the spring, and also in the November following. The best varieties in Sicily are grafted, and also budded upon the stock of the wild fig, this operation being performed also upon healthy trees of the best varieties, and the time chosen for it in March, or when the trees are in blossom in June. Great care is exercised in the cultivation of the tree to remove all dead and diseased branches, and to avoid too much cutting and pruning. The fruit is dried in the following manner. It is gathered when partially ripe, that is when the fruit is more green than ripe, and immediately plunged into boiling water, and allowed to remain only a very few minutes. It is then placed in a spot sheltered from the sun, and the next morning, at sunrise, spread upon a platform in order that it may be flooded with sunlight, care being taken not to place it upon the ground on account of its dampness. While drying, shallow willow-work baskets are used for holding the fruit, and these are never placed upon the ground, but kept in an erect position. At sundown the fruit is covered to protect it from the night dews or unexpected showers of rain, and this operation is continued for several days until the fruit becomes thoroughly dry. When dry it is placed in layers in small boxes or baskets, these layers being arranged very nearly and artistically, the fruit being pressed down firmly by hand until the box or basket is full, when they are securely covered and kept in a dry place ready for shipment.—*Journal of the Society of Arts.*

YANKEE NOTIONS IN REGARD TO COFFEE.

An enterprising American inventor has patented a process by which he intends to disguise corn, barley, wheat, beans, and other amylaceous substances by means of extract of willow bark, till a connoisseur cannot tell the product from coffee. There has been a great deal too much ingenuity exercised in this direction already, but inventors of spurious coffee and those who have taken them up might study with advantage the history of the notorious Date Coffee Company.

Quite a stir has been made through the New York Board of Health's examination into the use of mineral poisons for colouring coffee. Dangerous substances have been used, including lead and arsenic, which penetrate the bean, and cannot be removed by any process the coffee undergoes prior to its use by consumers. The beans are coloured in obedience to popular prejudice. It is curious that in certain sections of the country where consumers roast and grind the raw bean they will only buy coffee of some peculiar hue. One locality demands a bright yellow, other places want a black or olive—green bean. The result is the use of bone black, Venetian red, chrome yellow, heavy spar, and arsenic. Different processes of sweating coffee are also in vogue. Some varities of coffee are much improved in flavour and appearance by the operation. The best method subjects the bean to the influence of a moist but high temperature for about a week. The coffee is placed in a compartment that is built somewhat similar to the hold of a vessel, and through which heat is conveyed by means of iron pipes. Water in shallow pans is placed over the pipes, in order to provide the needed moisture. The temperature is gradually raised until it reaches 160° or 170° Fahr. A great deal depends upon the condition of the bean and the skill of the operator. Java coffee, green in colour, receives a dark brown hue that is a favourite with consumers, who take it as an index of age, and willingly pay 2c. to 3c. per lb. more on that account. The process removes from the beans a great deal of coffeo-tannic acid. This oxidises rapidly and forms other acids. It is upon the changes wrought in these acids that colour depends. By the sweating process Central American, Venezuelan, and other coffee, notably Mexican, are transformed into old Government Java, and sold for such. The operation is made an avenue to fraud. Imitation Java is palmed off for the genuine at tremendous profits.—*Indian Mercury.*

SCHOOL OF FORESTRY *VS.* AGRICULTURE.

One main result, we trust, of the International Forestry Exhibition at Edinburgh closed on the 11th instant, will the organization of a proper School of Forestry, where the principles of the science may be thoroughly taught, and the art exemplified by the resources with which Edinburgh and its neighbourhood abound. Whether a perfectly independent School of Forestry should be started, or whether it should not take the form of a general School of Agriculture, embracing tuition and training in the principles underlying all successful cultivation, whether of animals, of trees, of fruit trees, of cereal crops, of plants in general, is a question which we hope will be well considered. For our own part, seeing the great necessity there is for a thorough education in general principles, we would fain hope that the teaching in the school should not be restricted to forestry, but should at least comprize scientific agriculture and horticulture. The basis of all is identical, and a man thoroughly well grounded in the principles of physics,

physiology, systematic botany, chemistry, geology, mensuration, is placed in the best possible position to devote himself successfully in after life to the practical pursuits of agriculture, gardeoing, pomology, or forestry, according to circumstances. No doubt, legal and fiscal restrictions, and foreign competition will in the future, as now, hamper the cultivator and prevent him from fully availing himself of the increased means which scientific training, coupled with practical experience, will put into the hands of the cultivator; but that is no reason why he should not get all the advantages he can. From our personal experience we can testify that young gardeners and foresters, in Germany more particularly, but also in Belgium, France, and Denmark, have much better opportunities of becoming acquainted with the A. B. C. of their future life-work than the corresponding class in England, and they avail themselves of them too. In consequence, their competition is likely to become increasingly severe, the more so as they are willing to work for lower wages than are the corresponding class here. Their wants are fewer, their expenses less, and they are not puffed up by a little learning, but know how to use their hands as well as their heads. It must be remembered that we have to supply labour, not only for our own forests and gardens, but to skilled labour and supervision for our colonies and for India. The proper tillage and the full development of the resources of the vast areas constituting Greater Britain devolve to a large extent upon supplies from the home country. There can be no doubt which is the more likely to succeed—the raw lad, the know-nothing, or ne'er-do-well, or the well-trained student of an agricultural or forestry college. Look, too, at the enemies we have to encounter—the insects which ravage, the fungi which destroy our crops and our trees. We know but too well the effects of the Potato fungus, the Vine-growers among our neighbours across the Channel have been all but ruined by hosts of tiny insects, not unknown in our own vineries. Are we to go on for ever blundering along in our contention with these enemies, trusting more to chance and to the accident of season to tide us over difficulties, or are we to be guided by thorough knowledge of the nature and tactics of our enemies and the rational inferences to be drawn from them? No doubt it is true that great discoveries must continue to be made by the specialist, and the man who has the competence, the inclination and the time to bestow on that pecuniarily most unremunerative occupation, scientific research. But the power of turning these observations of the scientist to good account can only be exerted by those sufficiently well drilled to be able to see the insignificance of his researches, and this power can by no other means so surely be obtained as by means of the thorough training to be had in a well-equipped School of Forestry, Agriculture, or Horticulture.—*Gardeners' Chronicle.*

THE FALLING LEAVES.

As the time of year is upon us when trees and shrubs begin to shed their leaves, a few remarks bearing upon the subject may not be without their value to the practical gardener. In considering the question, it is necessary to bear in mind that the natural aim of every plant is to produce a perfect seed, and that when growing in a soil and climate adapted to its special habits and peculiarities, it produces no more of each organ that it requires for the healthy perpetuation and reproduction of seed. When the leaf has fulfilled its office, the nutritive fluids circulating through it are withdrawn and it decays or dries up. These fluids are absorbed in great part by the stem, through the agency of the roots, and rising higher and higher are at length deposited in the seed; the functions of the foliage being performed the leaves drop off, to be renewed in the following spring. Some interesting experiments of Zöller and Kissmüller* have shown that while in early summer the leaves of plants contain very considerable amounts of nitrogen, phosphoric acid and potash, these substances are withdrawn into the wood of the tree with the advancing season, so that before the leaves fade they have lost the larger part of what was most valuable in them, which the tree retains for its future use.

In some of these investigations on the leaves of the Beech tree it was shown that in their water-free substance the highest "percentage amount" of nitrogen, phosphoric acid, and potash is found when they open or expand in the month of May, and this percentage quite regularly decreases till they ripen and fall, but the "absolute" amount of nitrogen, phosphoric acid, and potash is greatest in July, and from that time on decreases. At the Connecticut Agricultural Station last year samples of leaves were carefully picked from an Oak tree and from a Chestnut (Castanea vesca) on the following dates:—October 16 and November 13, and submitted to analysis. On October 16 the leaves were bright green, and showed no signs of fading or changing colour. On November 13 the leaves were brown, having almost entirely lost their reddish tinge. Leaves were falling from the trees, but not rapidly.

Analysis of the Fresh Leaves.

	Oak.		Chestnut.	
	Oct. 16.	Nov. 13.	Oct. 16.	Nov. 13.
Water	56·6	29·7	60·2	31·7

Silica, &c.	·317	·642	·100	·208
Total...	2·330	3·800	1·813	2·975

The leaves gathered on October 16 had very nearly finished their assimilating functions, while those gathered on November 13, we may assume, had nearly or quite ceased to lose through resorption into the wood.

The green Oak leaves lost between one-third and one-half of the percentage of nitrogen in their water-free substance between the time that they began to change colour and the time when they became brown (dead). The correspondiug gain is found chiefly in the woody fibre and in the ether extract.

From the data obtained by the analysis of the Oak and Chestnut leaves gathered on November 13, it is seen that the newly fallen leaves, with about 30 per cent of water, contained in 100 lb.:—

	Oak.	Chestnut.
	lb.	lb.
Nitrogen	54	67
Potash	17	38
Phosphoric acid	26	23

Stable manure, with 70 per cent of water, contains about 5 lb. nitrogen, 6 lb. potash, and 3 lb. phosphoric acid. It must, however, be remembered, that while the nitrogen in stable manure is readily available as plant-food, it is exceedingly likely that the nitrogen of fallen leaves is comparably inert. From these facts we learn that Nature, in causing trees periodically to shed their leaves, returns with them to the soil a very large portion of the soluble inorganic substances which had been drawn from it by their roots during the season of growth. The amount of leaves which fall yearly, according to Ebermayer,* varies considerably, being larger in wet seasons than in dry—larger on a rich soil than on a poor one. It also varies with the thickness of the forests. Other things being equal, trees produce more foliage when standing apart than when standing in dense woods.

The degree of rapidity with which, under ordinary circumstances, leaves undergo decay, has also considerable influence upon the extent to which the soil is capable of

* *Landwirthschaft, Versuchs-Stationen,* xvii, 30.

* *Versuchs-Stationen,* xviii, 63.

being improved by any species of tree. The broad leaves of the Ash, Maple, and Sycamore, decay more quickly than those of the Oak and Beech, and these latter more rapidly than the needle-shaped leaves of the various Pine tribes. If the gardener desires to hasten the decomposition of fallen leaves for the purposes of compost, soils, or manures, it is necessary to add to them lime, wood-ashes, &c., as well as earth, pond or ditch-mud, and vegetable refuse generally. They will then be found to form an exceedingly useful material for potting purposes. If a bushel of common salt (to six bushels of lime) be dissolved in water and the brine be used to slake the lime, the action will be much more rapid, and a few weeks will suffice to set up a decomposition, when the heap may be overhauled, and the compost will be ready in a few weeks more. Instead of salt, muriate of potash may be advantageously used. It will probably act as well in the compost, and will also supply indispensable potash to the plants.—J. J. W.—*Gardeners' Chronicle.*

ERYTHROXYLON COCA.*

BY DR. SQUIBB.

The condition of the principal markets of the world for this drug for the past six months has been exceptionally bad. That is, whether good coca was sought for in the ports of Central and South America, or in London, Hamburg or new York, the search, even without limitation in price, was almost invariably unsuccessful. Not that the drug, independent of quality, was scarce, for hundreds of bales were accessible at all times, but the quality was so poor as to be quite unfit for use. The samples, instead of being green and fragrant, were brown and odourless, or musty and disagreeable, at once condemning the lots they represented, to the most casual observation, and yet the price was high enough to have represented a good article. The best that could be done, by the most careful buyers, was to accept occasional parcels, the best of which were of very inferior quality, and therefore unfit for medicinal uses, and these at very high prices. Coca is well known to be a very sensitive and perishable drug, only fit for its somewhat equivocal uses when fresh and green, and well cared for in packing and transportation. Very much like tea in this and other respects, it should be packed and transported with the same care and pains, in leaded chests, or in some equivalent package. It is very well known that tea if managed, transported, bundled and sold as coca is, would be nearly or quite worthless, and therefore coca managed as the great mass of it is, must be nearly all of it comparatively worthless. It used as tea is, this would probably soon appear but when used as a medicine which has been highly extolled and well advertised, it seems to go on equally well whether of good or bad quality. It is pretty safe to say that nineteen-twentieths of the coca seen in the United States market within the past two years must be almost inert and valueless, yet all is sold and used, and its reputation as a therapeutic agent is pretty well kept up. At least many thousands of pounds of the brown ill-smelling leaf, and of preparations made from it are annually sold. And worse than this, considerable quantities of a handsome looking green leaf, well put up and well taken care of, have been sold and used as coca, when wanting in nearly all its characteristics.

The writer for more than a year past has seen but one or two small lots of moderately good coca, and in common with other buyers has been obliged to buy the best that could be found to keep up his supply of the fluid extract. Almost every purchase has been made on mental protest, and he has been ashamed of every pound of fluid extract sent out, from the knowledge that it was of poor quality; and there seems to be no more prospect of a supply of better quality than there was this time last year, because so long as an inferior quality sells in such enormous quantities at good prices the demands of trade are satisfied.

Under this condition of the markets the writer has finally decided to give up making a fluid extract of coca, and has left it off his list, adopting a fluid extract of tea instead, as a superior substitute, for those who may choose to use it, and regrets that this course was not taken a year ago.

The character of coca as a therapeutic agent is not very good. The florid stories of a multitude of travellers and writers, up to and including the testimony of Dr. Mantegazza, received a considerable support from so good an authority as Sir Robert Christison, who reported very definite results from trials made upon himself, and upon several students under his immediate control and observation; and his results seem to have led to a very careful and exhaustive series of observations at University College, London, by Mr. Dowdeswell. This paper, published in *The Lancet* of April 29 and May 6, 1876, pp. 631 and 664, is entitled "The Coca Leaf, Observations on the Properties and Action of the Leaf of the Coca Plant (Erythroxylon Coca), made in the Physiological Laboratory of University College, by G. F. Dowdeswell, B. A." The results of these investigations were absolutely negative, and at the close of the work the investigator says: "Without asserting that it is positively inert, it is concluded from these experiments that its action is so slight as to preclude the idea of its having any value either therapeutically or popularly; and it is the belief of the writer, from observation upon the effect on the pulse, etc., of tea, milk and water, and even plain water, hot, tepid and cold, that such things may, at slightly different temperatures, produce a more decided effect than even large doses of coca, if taken at about the temperature of the body."

Conflicting and contradictory testimony from competent authority is not uncommon in therapeutics, and the reasons for it are well recognized in the impossibility of an equality in the conditions and circumstances of the investigations, and hence the general decision commonly reached is upon the principal of averages.

There can hardly be a reasonable doubt that coca, in common with tea and coffee and other similar articles, has a refreshing, recuperative, and sustaining effect upon human beings, and when well cultivated, well cured, and well preserved, so as to reach its users of good quality and in good condition, it is at least equal to good tea, and available for important therapeutic uses. Mr. Dowdeswell supposed that he used good coca, but it is very easy to see that with any amount of care and pains he may have been mistaken in this. Had he but used the same parcel of coca, that Sir Robert Christison did, the results of the two observers would be absolutely incomprehensible; and the results, in the absence of any testimony on that point, simply prove that the two observers were using a different article, though under the same name, and possibly with the same care in selection. On Sir Robert Christison's side of the question there are many competent observers whose testimony is spread over many years; while on Mr. Dowdeswell's side there are fewer observers. But there has been no observer on either side whose researches have been anything like so thorough, so extended or so accurate as those of Mr. Dowdeswell. Indeed, no other account has been met with wherein the modern methods of precision have been applied to the question at all; the other testimony being all rather loose and indefinite, often at second or third hands, or from the narratives of more or less enthusiastic travellers. But if Mr. Dowdeswell's results be accepted as being conclusive, the annual consumption of 40,000,000 of pounds of coca at a cost of 10,000,000 dollars, promotes this substance to take rank among the large economic blunders of the age.*

The testimony in regard to the effects of tea, coffee, Paraguay tea, Guarana and Kola nuts is all of a similar character to that upon coca. Each of these substances seems to have come into use independently, in widely separated countries, to produce the same effects, namely, to refresh, renew or sustain the physical and mental organism, and it was a curious surprise to find, after they had all been thus long used, that although each came from a different natural order of plants, the same active principle, namely, caffeine, could be extracted in different proportions from all. It is now still more curious, however, to find that for centuries another plant, namely, coca, yielding a different principle, has been in use for similar purposes the effects of which differ as little from those of tea, coffee, etc., as these do among themselves. Yet cocaine is chemically

* From *Ephemeris*. July, 1884.

* An excellent summing up of the character and history of coca, from which some of the writer's information has been obtained, will be found in 'Medicinal Plants,' by Bentley and Trimen, vol. i., article 40.

very different from caffeine, simply producing a similar physiologica effect in much smaller doses. All these substances in their natural condition seem to be identical in their general physiological effect, but idiosyncrasy, ordifferent individual impressibility or sensitiveness, causes a different action, as well in quality as in degree from the different substances, upon some persons.

In order to try to throw a little additional light on the comparative activity of the principal individuals of this group of substances, the following trials were made. It is generally admitted, and is probably true, that the same power in these agents which refreshes, recuperates, and sustains in the condition which needs or requires such effects, also counteracts the tendency to sleep or produces wakefulness when a tendency to sleep exists, and, therefore, if a tendency or disposition to sleep could be prevented by these agents, this tendency might be used as a measure of their effects when used in varying quantities, and thus measure the agents against each other for dose, or quantitative effect. In this way the proposition is to first measure coca against tea, then coffee against guarana, and finally to compare the four agents, using pure caffeine as a kind of standard to measure by.

An opportunity for such trials occurred in a healthy individual sixty-five years old, not habituated to the use of either tea, coffee, tobacco or any other narcotic substances, of good physical condition and regular habits, and not very susceptible or sensitive to the action of nervines or so-called anti-spasmodics. Quantities of preparations of valerian, asafœtida, compound spirit of ether, etc., which would yield a prompt effect upon many individuals seem to have little or no effect upon him, nor do moderate quantities of wines or spirits stimulate him. That is to say, he has not a very impressible nervous organization, is not imaginative, nor very liable to accept results on insufficient or partial evidence.

Fully occupied with work, both physical and mental in due proportion, for more than ten hours every secular day, when evening comes he finds himself unable to read long on account of a drowsiness supposed to be of a purely, physiological character. With a full breakfast at about 7-30, a full dinner at about 2-30, and a light evening meal about 7; and no stimulants or tea or coffee at any time, he finds, as a matter of not invariable but general habit, that by half-past 8 drowsiness becomes so dominant that it becomes almost impossible, and generally impracticable, to avoid falling asleep in his chair while attempting to read, even though ordinary conversation be carried on around him.

The first trial to combat or prevent this drowsiness was made with caffeine. The first specimen used was a very beautiful article made by Merck, of Darmstadt, and after that by pure specimens made for the purpose, the two kinds being found identical in effect.

Commencing with a one grain dose at abaout 6-30 p.m., on alternate evenings, leaving the intermediate evenings in order to be sure that the nightly tendency still persisted —and increasing by half a grain each alternate evening, no very definite effect was perceived until the dose reached 2½ grains, and this dose simply rendered the tendency to sleep resistible by effort. After an interval of tthree evenings with the tendency to sleep recurring with somewhat varying force each evening, a dose of 3 grains was taken—the maximum single dose of the German Pharmacopœia. This gave a comfortable evening of restedness, without sleep, or any very strong tendency to it until ten o'clock. Without anything to counteract sleep, the rule was to read with difficulty by nine, without much comprehension by a quarter-past nine, and either be asleep, or go to bed by half-past nine. The 3 grain dose of caffeine repeatedly obviated all this discomfort up to ten o'clock, but did not prevent the habitual, prompt and sound sleep, from the time of going to bed till morning.

This was the model established, upon and by which to measure all the other agents, and they were never taken nearer than on alternate evenings, with occasional longer intervals, especially when the final doses of record were to be taken.

The next agent tried in precisely this same way was coca, and knowing that the quality of that which was attainable was very low, the commencing dose of the leaf in substance was 2 drachms, or about 8 grams. This gave no very definite effect, but 2½ drachms did give a definite effect, and a subsequent dose of 2½ fluid drachms of a well made fluid extract of coca gave about the same effect as 2½ grains of caffeine. Three fluid drachms of the fluid extract were about equivalent to 3 grains of caffeine.

Both the coca used and the fluid extract were then assayed by the modern methods, for the proportion of the alkaloid they contained.

The only assays of coca that could be found conveniently were those of Dr. Albert Niemann, of Goslar, given in the *American Journal of Pharmacy*, vol. xxxiii., p. 122, who obtained ·25 per cent and of Prof. Jno. M. Maisch, in the same volume of the same Journal, p. 496, who obtained 4 grains of alkaloid from 1,500 grains of coca, which is also about a quarter of one per cent. These assays were, however, very old, and made by the old process. The process used by the writer was the more modern one of Dragendorff slightly modified. It was as follows:—

Thirty grams of powdered coca, thoroughly mixed in a mortar with 8 grams of caustic magnesia, was stirred into 200 c.c. of boiling water, and the mixture boiled for ten minutes. The liquid was filtered off, and the residue percolated with about 60 c.c. of water. It was then again stirred into 150 c.c. of boiling water, and was again boiled and percolated until apparently thoroughly exhausted. The total liquid, amounting to more than 600 c.c., was evaporated on a water-bath, commencing with the weaker portions, so that the stronger ones might be exposed to the heat for the shortest time—until reduced to about 20 c.c. This liquid extract was transferred to a flask and vigorously shaken with 50 c.c. of strong ether. The ether was poured off, as closely as practicable, into a tared capsule, where it was allowed to evaporate spontaneously. A second and third portion of ether, each of 50 c.c., were used in the same way, and then the whole evaporated to dryness in the capsule. A scanty, greenish, oily residue was left in the capsule, in which there was no appearance of a crystallized alkaloid. The capsule and contents were then weighed and the weight noted. The oily residue was then repeatedly washed with small quantities of water, until the washings no longer affected litmus paper. The oily matter adhered to the capsule during this process, no part of it coming off with the washing, and at the end of the washing the capsule and contents were again dried and weighed, and the weight subtracted from the original weight. The difference was taken as the alkaloid cocaine, and it amounted to ·077 gram, equal to ·26 per cent.

Several preliminary assays were made in reaching this method. Some authorities recommend the very finely powdered mixture of coca and magnesia, or coca and lime to be at once exhausted with ether. Others recommend that the mixture be made into a paste with water, and after drying on a water-bath that it be then exhausted with ether. This is better, but neither of these methods were satisfactory.

Finally, 30 c.c. of a well made fluid extract of the same coca was thoroughly mixed with 8 grams of caustic magnesia in a capsule, and the mixture dried on a water-bath and powdered. This powder was then exhausted—one part by ether and the other part by chloroform, exactly as in the method given, both parts giving very slightly higher results. As a check upon the results the solution of alkaloid washed out was titrated with normal solution of oxalic acid.

From all this it would appear that this inferior coca of the markets, or rather the best that can be selected from it, yields about the same proportion of the alkaloid as was obtained by Niemann and Maisch, but it has been shown that, by the older processes of assay used by them, much of the alkaloid was probably lost or destroyed, and that much better results are generally obtained by the modern process.

Now, since 3 drachms of this coca, or 3 fluid drachms of its fluid extract gave the same physiological, or perhaps, therapeutical, effect as 3 grains of caffeine, and as the 3 drachms contained about ·45 grain of cocaine, it follows that cocaine is about 6·5 times more effective than caffeine, but it always follows that the coca accessible and even the very best coca, contains very much less of its alkaloid than those articles which yield caffeine do of that principle.

Having gone thus far with coca which it is proposed to abandon for the present, at least, and to substitute for it a better agent, the next step was to investigate that agent, namely, tea, in the same way.—*Pharmaceutical Journal.*

NEW CANDIDATES FOR CULTIVATION.

Out of the report of the Commissioner of Agriculture, U. S. A., for 1883, recently issued, amongst information of the highest value to the occupiers of land in the United States a few notes can be gathered which may prove beneficial to ourselves. The botanist of the department (Mr. G. Vasey) submits a paper "on the grasses of the great plains," which is illustrated by twenty-five full page engravings of uncommon but noteworthy plants for pasture. Several of these are, of course, wholly unfit for British cultivation; yet a few seem as if they might be deserving of attention from the rare students of agriculture who are seeking to enlarge the list of those forage plants which need no storage, and no cultivation after they are once rooted in the soil, and which fatten (or at least maintain in health) cattle in that out-of-doors, self-waiting-on condition of life which is, of all farm processes, the most likely to pay the occupier. Many of the new plans now being recommended for adoption in England among this class of persons call for large immediate outlay and continual expenditure, and therefore seem more likely to put money into the pockets of the tradespeople and other wage-takers than into those of Mr. Pay-for-all, the farmer. Festuca scabrella is described as a "native of the Rocky Mountain region" [therefore hardy] "with culms growing from 3 ft. to 5 ft. high, according to locality." It is called "bunch grass." Cattle are said to be fond of it, and it is considered "one of the most valuable wild grasses of the region where it grows." Calmagrostis (or Deyeuxia) Howellii is described as a recent discovery in Oregon, and also in Washington. "From its habit of growth and great abundance of foliage, this gives promise of being a valuable grass for cultivation." Bouteloua polystacha (low gramma grass) is stated to be one of many species called gramma in the arid districts of Texas, New Mexico, and Arizona. It is an annual 6 in. to 12 in. high. Near the banks of streams, where it abounds, it furnishes excellent pasturages.

Another mixture has been found very profitable in Carolina. One of the great pests of the cotton-planters there has been Cynodon dactylon, better known as Bermuda grass. This plant does not ripen its seed in America, but, having underground stems, when once established, is not easily killed by ordinary means or temperature. It has hitherto been looked on as a weed. But a few years ago the experiment was tried of planting the rhizomes and sowing with them red clover, whose roots feed deep, whereas the Bermuda grass is a surface feeder. The result was a very heavy crop, several years running, of hay, amounting to from 4,000 lb. to 6,000 lb. per acre, "which, baled and delivered on the cars at any railroad station, has ranged from $20 to $25 per ton; and it has met with as ready a sale as beef or mutton, cotton, or any other product of the farm." Are we looking out as eagerly for new farm plants or new methods of utilizing old ones, as are the correspondents of Mr. Vasey?—A. P.—*Field*.

SOMETHING ABOUT COCONUTS.

The little street Arab when he buys his slice of coconut, or the more lucky young maiden when she eats her coconut pie with her silver fork and spoon, never gives a thought from where or how the nut that supplies the relish came into port.

"Annie L. Palmer" makes four round trips a year, and during her journey she is occupied in gathering the finest coconuts grown in Central America. When she starts from this port she is loaded with a variety of American produce, which she dispenses at various calling ports along the coast of Honduras and the United States of Colombia. Stopping at Saint Andrews we find the population to consist principally of negro emigrants from the West India Islands. These people are in reality coconut farmers. They grow coconuts in a similar manner to what our North-western farmer grows wheat, but hardly so extensively, for their territory is somewhat limited.

Cultivating coconuts no doubt suits the inclinations of the negro, for after the trees are once come to maturity they require little manual labour to keep in order.

This comparatively new industry has benefited the condition of the population very materially, some of them possessing plantations that pay well. It is a common occurrence to find them making a profit of from $300 to $350 per month, and in one case a negro named Blackey possesses a fine plantation, upon which he clears an average of $500 a month. In Saint Andrews all goods that are sold to the people are free of duty, but the captain of the ship is obliged to pay a license of $20. This port possesses a very fine harbour and the trade in coconuts is increasing.

It sometimes happens that the Captain is not able to dispose of the whole of his cargo at the above port. This being the case, he leaves on a tour of the following places:—Old Providence, Corn Island, Pearl Cay Lagoon, Grey Town, Port Lamont, Bogas Bilcora and Blewfields. Principally the business is done on barter. The natives, who are a mixed race, purchase calicoes, white cotton and prints, flour, provisions, boots and shoes, &c. In most cases they pay for these in coconuts, at the rate of 1,000 nuts for $30 worth of general supplies. The duty upon goods sold in this way is 2½ per cent. Sometimes it happens that there are no nuts, and then they pay, if it be in the United States of Colombia, with coin, there being no paper money.

The natives have many peculiarities; one of them, and perhaps the strangest, is that they have a novel way of saving their money by burying it in the ground and thus making mother earth act as a safe. Although the native language in this part of the continent has been for quite a long time Spanish so great has been the influence of American traders that English is now spoken by nearly all, and is the language of trade, only a few officials speaking Spanish.

The very finest coconuts that are grown in these regions are shipped to this country, and the lower grades are generally forwarded to Europe; $30 per thousand is the price for good average qualities. A peculiarity about the coconut harvest is that it goes on all the year round; this being the case the traders can nearly always depend upon getting a good return cargo in a reasonable time. The time it takes a nut to fully develop, that is, from the blossom to the ripening of the nut ready for gathering, averages fourteen months.

Having visited the neighbouring ports the captain then returns to Saint Andrews, and collects either his cash or coconuts, for the goods he left on his outward journey. As a rule, no credit is given. Cash or coconuts are the terms, but if the native is well known to the captain for honesty, then he can be accommodated.

Having parted with all his American produce and obtained all the nuts he wishes, he returns with them to New York, which he reaches in from 16 to 20 days after he sails. Thus it will be seen that before our street-arab, or the more lucky maiden can enjoy their coconut it has got through many vicissitudes.—*American Grocer*.

INSECT PESTS IN CEYLON.—Amongst the "Notes" in your last issue, p. 615, is an extract from a Ceylon paper of a report by Dr. Trimen as to an insect "which has caused much alarm by its depredations on cacao and cinchona plantations," and that Dr. Trimen thinks "the only serious damage to cacao comes from the *Helopeltis antonii*, which appears to be a recent importation to Ceylon, although well-known in Java." Quite recently I received from my friend Mr R. McLachlan some fragments of several specimens of a Hemipteron which he had received from Ceylon, identified as *Helopeltis antonii*, and said to be causing damage to the planters' crops, and my correspondent, having doubts as to the proper identification, had forwarded the specimens (!) for my examination. Before stating that an error of identification had been made, it is necessary to say what *Helopeltis antonii* really is. That species described by Dr. Signoret is a member of the Capsidæ, possesses nodulose or incrassated femora, and of course, like other members of that family, may be considered as injurious to some kinds of vegetation. The specimens I received (*sans* head and pronotum) had also nodulose or incrassated femora, and though somewhat similar also in colour to the *Helopeltis antonii*, clearly belonged to the Reduviidæ, whose habits and food are of a totally dissimilar character. It is therefore possible that both species occur in Ceylon; the one is being frequently mistaken for the other, a matter of some moment to the planter, as in destroying the Reduviid he may be at the same time killing the worst enemy of the real pest.—W. L. DISTAN, Russell Hill Road, Purley, Surrey.—*Nature*.

LIQUID MANURE.

The time for applying liquid manure to plants in pots requires some consideration. The time not to apply it is when a plant is newly potted and has no roots in the fresh compost, and when it is in a dormant state or resting. The time to apply liquid manure is when a plant has active roots, when the flower buds are forming, and when they are expandiug. Liquid manure can never be given wrongly at those times. When a plant is growing strongly in plenty of light and air, and flower buds are showing, the roots will take almost any amount of nutrition, which in the case of softwooded plants will need to be continued until the flowering is over. In the case of plants that make growth and set the buds and then rest awhile, the liquid will only be required until the growth is made, as, for instance, Camellias, Azaleas, &c., and through this stage liquid may be given, but at the resting time liquid manure is not necessary, or only in the case of weakly plants with a heavy crop of buds, and then in moderate quantity. When the buds take the next swelling or for flowering, the roots, if the plants are healthy, push active feeders, and these feed the swelling buds and expanding flowers, new growths issuing soon after flowering or in vigorous examples with them. If the manure is to be of any use it must be when the plant has an active root-action. Applied when the root-action is dormant, liquid manure will not do much good beyond enrich poor soil; but it may do great injury by gorging the soil with aliment which stagnates and destroys the roots. This is a common case with Camellias from an excess of water alone; the roots are lost during the resting season, and the buds fall when they should be expanding. There are cases when liquid manure may be given at almost any stage of a plant's growth, provided the foliage be fully exposed to light. I allude to plants kept in continuous growth and flowering, such as Gardenias, Tree Carnations, Eucharis, and Stephanotis.

Liquid manure must given to plants in accordance with their health. Weakly plants will not take such strong supplies as those which are vigorous, and it must be given less frequently. It is not considered desirable to give liquid manure to weakly plants, but these must have assistance if they ever are to become healthy. Poverty of plant is from poverty of soil. Starved roots can never support a vigorous plant, and if any plant need liquid manure it is the weakly and ill-conditioned. It is no use giving liquid manure to a plant that has bad foliage from lack of roots, but it is another thing to give it to a plant starved in a small pot full of hungry roots. Further, liquid manure should be given weak; when too powerful it destroys the roots, and it should not be supplied too frequently. A plant in the early stages of growth after potting will not only require the liquid weak, but less frequently than when the roots are more abundant and the plant much advanced. As a rule once or twice a week is a safe practice until the plants are in free growth, and afterwards it may be given at each alternate, or, if more vigour is needed, at every watering. Whenever it is given it should be thorough—as full and complete as a supply of water, sufficient to fill the soil.

Liquid manure should always be employed of a known strength. No haphazard system must be followed, and although manures vary in strength and may be different in chemical constituents, those of the same kind are not so variable as to be unsuitable for practical purposes. I allude to solid manures, which when mixed with water are most suitable for pot plants. The drainings of stables, cow sheds, &c., are good, yet vary so much in strength from the water that finds its way into the cesspool, either from rain in the case of open tanks in yards or washing out of the trenches in stables, as to be very variable, and require great judgment in their employment. As a rule this form of liquid manure will mostly need to be diluted with six times the bulk of water, and in using the drainings of the stalls one part to twelve of water is quite strong enough, but the liquid manure tank is best left alone as regards watering choice plants with it, reserving it for the coarser or grosser-feeding plants or crops. Liquid manure should always be applied at a temperature equal to the mean of the house in which the plants are growing, or a few degrees warmer.

Soot is undeniably the best manure for plants in pots. It should be kept dry, as damp spoils it, and putting it in a tub with water and allowing it to stand until wanted is not much better. If a large quantity be wanted put a peck in a tub, and enough water to form it into a paste, then add thirty gallons of water, and apply at once, stirring well before each dipping of the watering pot. Another plan is to put as much soot as is considered will be wanted in a watering pot and form it into a paste with water by stirring with a stick. Pour about a wineglassful into a gallon of water or more, according to the size of the can, and apply to the plants. For giving colour to foliage there is nothing to equal soot, giving the leaves a deep green gloss not to be obtained from any other manure that I know.

Guano, when good, is first-rate. Peruvian being the best. Place 1 lb. in a tiffany bag, and immerse it in a tub containing twenty gallons of water, then move it about until nothing is left in the bag but the insoluble matter, and apply at once. If only small quantities are required put as many ounces in a tiffany or muslin bag as the watering pot contains gallons, and move it in the water until it ceases to give out more colour than that of the liquid outside the bag in the can. It is then fit for use.

Sulphate of ammonia may be used at the rate of half an ounce to the gallon of rain water to plants that have plenty of roots, and should not be given more frequently than twice a week; but it is safer to use it at half the strength —viz., quarter ounce to each gallon, and apply more frequently. This is perhaps one of the best manures for plants grown for their leaves, and is more especially useful for Chrysanthemums, and Fuchsias. The ammoniacal liquor from the gasworks is also serviceable, employing a pint to three gallons of water, and superphosphate of lime at the rate of 1 lb. to twelve gallons of water may be used similarly. The nitrates of potash and soda are good where vigour or leaf-growth is wanted, as they promote luxuriance in a marked degree; but all such manures should only be given to plants that are strong-rooting, and not to delicate-rooted ones.

In using liquid manures the best results are obtained by varying the applications—not employing one kind throughout, but alternating, as for instance soot for a time, then animal manure, and then superphosphate of lime, &c., and this course seems to act most beneficially on soft-wooded plants.—G. ABBEY.—*Journal of Horticulture.*

THE WORLD'S OIL-SUPPLY IN THE NINETEENTH CENTURY.

The possibility of utilizing coal gas as an artificial light had, indeed, been proved in 1792, when Mr. Murdoch devised an apparatus for thus lighting his own house wall, and subsequently he had applied to the manufactories at Soho and Salford. But the notion of thus illuminating cities was not mooted till 1802, when M. le Bon suggested its use in Paris, and in the following year Mr. Winsor lectured on the subject in London. Of course many more years elapsed ere this new discovery was generally adopted in minor towns; and the inhabitants of rural districts continued, as heretofore, chiefly dependent on tallow or train-oil.

For a moment let us glance at the principal sources of animal and vegetable oil-supply, ere the fountains of mineral oil were revealed for the use and comfort of the human family.

First and foremost, of course, ranked the fish-oils—the well-known train (or *drain*) oil, which drained from the blubber of the great Greenland whale (a large whale sometimes yielding full thirty tons of blubber—each ton representing nearly two hundred gallons of oil). Though the cachalot, or sperm whale, could never rival the Greenland whale in the quantity of its contribution it had, at least the advantage of quality and variety, since, besides ordinary blubber, it yields a large amount of sperm-oil, and also of spermaceti. Of the latter valuable product, the head alone often yields ten barrels.

Next among oil-yielding fish come the grampus, or dolphin, the porpoise, the shark, the seal, the cod, the herring, and others.

Of animal-fats are butter, tallow, lard, goose-grease, neat's-foot oil (prepared from the feet of oxen, and used by currriers in dressing leather), and mare's grease (imported from Buenos Ayres and Monte Video, where a multitude of horses are annually slaughtered for the sake of the hides, tallow, and bones!) in Russia, especially at Moscow, yolk-of-egg oil is in great repute for making soap and pomatum.

Vegetable oils form a very important item in our supplies, inasmuch as oil-seeds to the value of £5,500,000 are annually imported into Britain for crushing purposes, and our exports of oil are roughly valued at £1,600,000. The export of seed-oil from London, Hull, and Liverpool, in 1880, was 14,508,000 gallons.

Under the head of seed-oils rank linseed, cotton-seed, and castor-oil. Colza-oil, also, is made from mustard, hemp, radish, rape, turnip, and other seeds. Then we have olive-oil and almond-oil. From India comes poppy-seed oil; from the Black Sea, oil of sunflower-seeds. From Ceylon and the Pacific Isles comes coconut-oil. From Western Africa the palm-nut oil of the oil-palm, and oil of ground-nuts for use in fine machinery. From Singapore and China we receive kokum-oil and vegetable tallow. About fourteen thousand tons of croton-oil are annually imported for the use of the wool-dressers of Britain.

Besides, these, so familiar to ourselves, almost every country has some speciality in oils. Thus, in Southern Russia, tobacco-oil is largely used; in Italy, oil of grape-stones; in China, oil of tea-seed; in India, oil of nutmegs, of seeds of the gamboge-tree, of custard-apple seed, of cashew-nut, of cardamom, of mean, of margosa, and many others. Brazil, too, has a large number of oils, both animal and vegetable, peculiar to itself.

In this connection, and bearing in mind Lelyveld's essay on smoothing the waves with tar-oil, we note that Great Britain annually imports five million gallons of wood-tar, and that about an equal quantity is made in the country from coal at the charcoal-work, the gas-work, and the bone-factories.

From a very much shorter list of materials than those here enumerated, our grandparents derived all their artificial light. We, their fortunate descendants, have not only added to these, but are now in the enjoyment of such vastly developed resources, that in this respect, at all events, the nineteenth century may claim to be an Age of Light. Strange indeed is it to remember, that for its first quarter the cumbersome flint and steel still held their place in every household, and good housewives rejoiced when rude brimstone matches, six inches long, with point dipped in sulphur, were invented to receive the spark thus obtained. How would they have marvelled to learn that within fifty years many factories in various parts of Britain would each be turning out their ten million *per diem* of neat matches, warranted to ignite at a touch! And yet that development of the light-bearing lucifer is but a trifle compared with the materials on which it has to act.

To M. du Buisson, a Frenchman, is due the credit of first attempting to distil oil fit for burning from the bituminous shales hitherto deemed worthless. He succeeded in his experiment, but the shales of France were not found to yield oil in paying quantities. An effort was made to apply the same process to the bituminous shales of Dorsetshire, and "Kimmeridge coal" was found to yield a much larger proportion of oily matter. It was, however, found impossible to overcome the noxious smell of the various products, so that this enterprise did not command large success.

About the year 1847 Sir Lyon Playfair discovered a petroleum spring at Riddings, in Derbyshire, to which he called the attention of Mr. James Young, a Manchester chemist, who proceeded to distil it, thereby obtaining a clear thin burning oil, and also a thick lubricating oil. Certain solid crystals floating in the petroleum suggested the presence of paraffin, and the possibility of obtaining a candle-making substance. This resulted in the manufacture of the two first paraffin-candles, and these were lighted by Dr. Playfair to illustrate the novel subject at a lecture to the Royal Institution, when he foretold that ere long they would become the common light of the country—a prophecy which was very quickly realised, but not from the Derbyshire springs, as those were soon exhausted.

Mr. Young's attention was next attracted by seeing oil dripping from the roof of a coal-mine, which led to further experiments, with the result that cannel-coal was found to be essentially oleiferous. The discovery near Bathgate, in Linlithgowshire, of a very rich coal-gas, like the celebrated Boghead coal, led to the establishment of a distillery in its neighbourhood, the coal being broken up into fragments like road-metal, and heated to a red-heat in cast-iron retorts. A ton of this coal was found to yield about 120 gallons of crude oil. This being subject to a second distillation, resolved itself into certain proportions of light oil for burning, thick oil for machinery, a small quantity for naphtha, and a large residuum of paraffin, which, when purified with animal charcoal, is transformed into a substance like beautifully white wax.

Great was the interest excited by this discovery, but difficulties were thrown in the way of Dr. Young's obtaining a patent for his invention, as it was proved that many years previously Reichenbach had tried a similar experiment, and by distilling 100 lb. of coal had obtained 2 oz. of an oil resembling naphtha. Young, however, carried the day, and his now celebrated patent was granted in 1850.

It was not till six years later that any fresh attempt was made thus to utilize the great beds of bituminous shale which are so extensively found in carboniferous districts, but which had hitherto been totally neglected. These have been found to yield from 30 to 50 gallons of crude oil per ton, and great works for the manufacture of mineral oil have been established at many places in England, Wales, and Scotland. In the latter alone it is stated that upwards of 800,000 tons of bituminous shale are annually distilled, yielding

25,000 gallons of oil.
5,800 tons of paraffin.
9,800 „ of lubricating oil.
2,350 „ of sulphate of ammonia.

"Greater Britain" was not slow to adopt the new industry started in the mother country. In 1865 New South Wales discovered among its hid treasures a shale similar to the Boghead coal of Scotland, but considerably richer in oil and less sulphurous. A sample was brought to Sydney for distillation, and one ton yielded 160 gallons of oil. Thereupon the New South Wales Shale and Oil Company was established, and seems to have developed into a very important industry.

America had taken up the subject earlier. In 1854 the Kerosene Oil Company and several other companies were started to distil oil from coal, and by 1860 upwards of fifty factories for this work had been established in various parts of the States.

Then came the discovery of real mineral-oil wells, which so quickly revolutionise the oil traffic of the world here. Here, as in most other cases, we have evidence of the "nothing-new" theory; for since King Petroleum has asserted his power, men marvel to find traces of ancient workings, proving that bygone generations had discovered the native oil—so long ago, that very old trees of several centuries' growth have been found growing in the excavated ground. From some strange cause unknown, these oil-seekers had abandoned their work, and (although mineral oils were known to exist in Asia), their presence in America had been altogether forgotten, when, in 1826, salt-workers who were engaged in boring brine shafts in Ohio were amazed to find that they had struck oil as well as brine.

Certainly it was known to the Seneca Indians of Pennsylvania that oil flowed from the rocks at various points in the Alleghany mountains; and a French traveller has recorded a curious incident which he witnessed in 1750, when the tribe assembled for a religious ceremony, at the junction of a small stream with the Alleghany river. The stream was covered with a thick oily scum, to which, after a solemn oration, the chief applied a lighted torch, Immediately the flames spread over the surface of the water, amid shouts of the red warriors.

In the same district, at the spot now known as Titusville, was a well, on the surface of which oil habitually floated; and the Indians, who had long known its healing properties (now so fully recognised in its refined form as vaseline), were in the habit of collecting it, by laying their blankets on the glassy surface of both well and stream, thus absorbing the oil, which they then wrung out, and stored for the use of the tribe. So early as 1833 an account was published in the *American Journal of Science* describing how certain persons made a living by skimming this dirty-looking and most unfragrant grease with their boards, and then purified it by heating, and straining it through flannel, when it was sold under the name of Seneeca oil, as an excellent specific for healing sores of man and beast, and curing sprains and rheumatism.

In 1853 it occured to Dr. Brewer that this natural oil

might be turned to account for lamps, and the Pennsylvania Rock Oil Company was formed to develop the idea, with very small result, however, till, in the year 1859. Colonel Drake's attention was attracted by the oil which oozed from fissures of the rock all along the stream now known as Oil Creek. He bethought him that since the rock was apparently saturated with this oil, there must surely be a reservoir, which, if it could be found and tapped, would yield a far larger supply than that which was so carefully collected by the Company. Little, however, did he dream, when he first communicated to them his idea, and was by them empowered to work it on their account what amazing results would attend his experiment.

He commenced sinking a shaft on the artesian-well principal, and had bored to a depth of 600 feet, when to his unspeakable delight, he found that he had indeed reached the main supply, and oil was henceforth pumped up at the rate of from 400 to 1,000 gallons daily. Very soon he was able to rejoice his employers with about 2,000 barrels of crude petroleum. New shafts were quickly sunk in every direction, and in the following year 500,000 barrels rewarded the lucky borers. The strike proved magical in another sense, for at once the price of crude petroleum fell from twenty-three cents per gallon to twelve cents, and that of refined oil fell from forty-five to thirty-two cents. Very soon this was further reduced to nine cents for crude oil and nineteen for refined! Already this precious "earth-oil" asserted its privilege of being a special boon to the poor.—*Royal Gazette.*

KEROSENE AS AN INSECT-KILLER.—It is maintained by Mr. R. McLachlan, F.R.S., that the most effective of all insecticides for fruit trees is "kerosene butter" diluted with water to the extent of from twelve to twenty times its bulk. This butter is prepared as follows:—Pure kerosene, 1 gallon; condensed milk, 1½ pint; water, 3 pints. The milk and water are mixed, the oil added, and the compound churned till it forms a butter. The insecticide is applied by washing or syringing as in the case of similar compounds. But seeing this remedy must be kept in constant agitation while using, or else the kerosene rises to the surface, and that the butter needs the churning process, I am inclined to think its practical worth is overrated.—ENTOMOLOGIST.—*Journal of Horticulture.*

STRIKING CUTTINGS IN WATER.—Striking cuttings in water is a very simple and certain operation. All that is needed is some clear rain water, some pieces of charcoal, and some clean bottles; pint champagne bottles are as good as any, but others with flat bottoms will do. Place in each a few pieces of charcoal about the size of a walnut, then fill the bottles with water, and stand where you intend them to be whilst the cuttings are rooting, which is best where they will be shaded from the direct rays of the sun. When the bottles have been in the house twenty-four hours, by which time the water will have become warmed to the mean temperature of the house, take the cuttings prepared as if they were to be inserted in soil, cut transversely below a joint, and remove only as many leaves as will allow of the stem being put in the bottles to the extent of a couple of inches, or at most three. The base of the cuttings should be in the water, and be covered about half an inch, which will be suitable for the first week, but in the second the cutting may be pushed lower into the water, yet never deeper than an inch. No shading is necessary, or anything different from that in which the parent plants are grown, and the little attention needed is to keep the bottles replenished with tepid water as needed, and in due course roots will be emitted plentifully, and when they have grown so as to be of a length and quantity that can be placed in a 3-inch pot, remove and pot at once. Just a little shade may be needed until the potting is recovered from, and the plants in a few days are as good as ever they will be for decorative purposes, provided, of course, they were in good condition to begin with, but if small they may need growing. This mode of propagation may be practised at any time of year. All that is necessary in the case of Crotons and Dracænas is to secure a little firm wood to the base of the cuttings, and not put them in when they are making young growth. How many other plants can be propagated in the same way I am not prepared to state, but I have no doubt that many could be so increased. It is a most interesting mode of propagation, and well deserving of more attention than has hitherto been bestowed upon it.—G. A.—*Journal of Horticulture.*

AUSTRALIAN BOTANY.—You will remember I referred in my former address to a valuable and extensive work on the eucalypti of Australia, undertaken by our state botanist and fellow member, Baron von Mueller, and you will be glad to hear that the 10th decade of the *Eucalyptography of Australia* is now in the press, and, with the exception of a few supplements, will complete this most important botanical work. Baron von Mueller has also been closely engaged in research concerning the regional distribution of the 14,000 already known Australian plants preliminary to further extension of his utilitarian inquiries into their structural characteristics as well as into their industrial and therapeutic uses. He informs me that through the liberality of the Government he is now able to issue a monography of the Myoporinæ, an extensive and important order of Australian shrubs, for which he has 80 plates already prepared; he proposes, also, shortly to prepare a new edition of the *Select Plants for Industrial Culture and Naturalization*, and that at the instance of the Field Naturalists' Club he hopes soon to issue a *Dichotomous Key* for the naming of Victorian plants—a work which will no doubt be hailed with pleasure by all botanical students among us.—*Mr. Ellery's Address to the Royal Society of Victoria.*

TEA IN CEYLON: THE YIELD OF MARIAWATTE.—Several of our correspondents having expressed doubts as to the authenticity of the figures given by us of the yield of this estate, we think it is well that we should once more reiterate what we previously stated. It has been suggested by more than one correspondent that the yield of the younger fields of Mariawatte has been added to that of the older tea in order to swell the average out-turn per acre. We are in a position to emphatically deny this. The estate consists of 100 acres of old tea, 60 acres planted at stake in July and August, 1883, and 140 acres just opened. The 60 acres, now one year old, were only topped last month, so they could hardly have added to the yield of the 100 acres, which is all that there is on the estate from which to pluck. Up to date, about 95,000 lb. of made-tea have been secured, *every pound of which came off the original 100 acres.* The whole of the estate is planted 4 ft. × ft., and there are a good many vacancies in the old 100 acres, as we can testify from personal inspection. We believe the yield has been variable from different portions of the estate, some it is estimated giving as much as 1,400 lb. an acre, whilst other portions yielded much less than the average. As an instance of what an estate in a favorable situation can do in the way of an enormous yield, we think this a wonderful example of most encouraging significance to all of us. There can be no doubt now that over 11,000 lb. of made-tea will be despatched from Mariawatte during this year, which we think is likely to remain the *champion* yield for some time to come.—Local "Times."

CULTURE BY THE KARENS IN BRITISH BURMAH.—The *Indian Agriculturist* thus quotes from the Forest Report of British Burmah:—Mr. Petley's report on the cultivation in the Karen Hills has also been incorporated with the annual report. Tea is reported upon favourably. He says:—"I find a fair yield of flushes from the shrubs at maturity and an excellent quality of tea turned out in the manufacture, supporting the credit of Darjeeling tea from whence the original seed came." With improved instruction and better knowledge among the labourers employed, he expects the outturn to be double that of last season. The coffee trees are also thriving. The mature trees are heavily laden, and as matters stand at present a very fair crop may be expected. Liberian coffee, however, thrives very slowly. The shoots from the coppiced stumps of last year's cinchona trees are coming on well; in fact, they are now quite young trees again. About 25,000 more plants and shoots have been planted out, a 700 lb. of bark prepared by Karens alone, from trees grown by themselves, has been sent to the London market, where it realized the market rates in competition with bark from other countries. Among fruits trees, citrons and pears have grown and increased in abundance. The potato crop has been exceptionally good. The Karens are keeping up the cultivation with great energy. The yield last year was sufficient to supply the troops of Toungoo and the bazaar; the produce appears to have been four and five fold and of good sizes. The seed principally sown has been the Bengal potato procured from Calcutta which, mixed with the acclimatized hill seed, does well.

ROSELLA CULTIVATION.

The cultivation of the rosella—*hibiscus sorbifolia*—is adapted for either large or small areas, and can be profitably grown on an extensive scale. Two preservers are now advertising that they are prepared to purchase this fruit in large quantities, and seeing that it is so easily grown, the supply in the coming season should be something like commensurate with the demand. Now is the time to make a commencement; the seed should be sown at once in a bed for after transplanting. Good seed that will germinate is hard to grow in the South of Queensland, but it can be saved plentifully in the North, and if only a few seeds germinate the cuttings grow so readily that it is no difficult matter to make a large plantation from a very few plants. Sow seeds at once in a warm border where they can be easily watered. Tread the seeds in firmly or roll them, and water them at once, and in a week or ten days they will make a start. When they are large enough to handle they may be transplanted, always choosing moist weather for removal. No very large number of plants is required for an acre, for they should be planted 6 ft. apart, and almost any description of worked soil will suit them. Over rich soil is not good for them, as they grow too rank and straggling, and are seldom in it sturdy and profitable. Moderately rich soil suits them best, as deeply worked as possible to give them a chance in a time of drought; for they will not bear well if wanting moisture in fruiting time. The time of bearing is May and June, and whenever they may be put in they invariably fruit about the same time. The fruit when stripped of its pod and seeds is worth about 3d. per lb. retail, and preservers will give something like that price, or 2s. to 2s. 6d. per lb. for the dried article. Rosellas are easily dried, and in that state can be kept almost any length of time as good as when fresh gathered. Eight pounds of the fresh fruit will dry into 1 lb., and can be packed in a bale and brought in almost any distance to pay. A bale of 1 cwt. of dried rosellas is worth about £11. They can be dried on sheets of iron in the sun, or in a cool stove oven. The rosella makes an excellent wine for summer use, a very good syrup for flavouring summer drinks, and can be preserved and made into jams and jellies which will hold their own in competition with the fruits of temperate climes. We believe there is money to be made by growing the rosella, and recommend cultivators who wish to turn their lands to account to plant an acre or so. The chief want is light labour to gather the fruit, which should be done carefully with scissors, and then the plants may be kept in bearing for months. It is indispensable that the rosella be grown in warm latitudes to be productive and lasting.—*Queenslander.*

SANDY SOIL FOR AN ORCHARD.

With a few modifications, the following, written by a correspondent of the *Country Gentleman*, is quite applicable to our Queensland climate:—

I put sandy soil next to the best soil for fruit trees, particularly for an apple orchard. Only an alluvial loam of the necessary depth and richness with perfect natural drainage exceeds it, and this mainly on account of the fertility it holds, being rich with ripe plant foods. Hence a sound healthy growth results, both of wood and fruit. This healthy condition, secured by drainage, is even more applicable to sandy soil, which may be rendered fertile by proper treatment.

Next to drainage is depth of soil. Sandy soil allows the roots to penetrate far beyond the reach of the frost and drought, which so seriously affect shallow-rooting trees. At this depth moisture never fails to be found, however dry the surface may be, unless in very light soil.

Such soil only needs manuring. There is no expense of underdraining, and little in preparing or cultivating. The heaviest and longest-continued rains pass off readily, and the manure they carry down is taken up by the roots, so that little or no fertility is lost. I know of apple trees in such soil that are nearly a century old, with a reputation of having been very productive, and that are still bearing fruit. The grains and grasses, having comparatively short roots, are readily affected by drought, particularly in our dry, climate, and hence unless the land is kept well manured and charged with vegetable matter there will be loss and sometimes total failure. The trees, under similar conditions, sustain themselves, grow, and mature their crops.

The most important thing with trees on sandy soil is to get them started, as their roots are short like those of the grains and grasses, and subjected to the same influences, the first year or two. With proper attention given to the soil and trees during this time, the roots will make sufficient depth to protect them against harm at the surface. Many trees set in light soils perish. There is no need of this. Enrich the soil with barnyard manure, and keep it well mulched with green vegetable matter, which should be worked into the soil when decayed, and a new mulch applied. In a severe drought wrap the stems of the trees with hay, put some hay among the branches, and apply water. In this way the most severe drought may be defied.

Sandy soil as a soil for fruit trees has been underestimated. Like other soils, it has not only been neglected, but the necessary enrichment withheld. Particularly has the mode of application been wrong. The quantity should be adjusted to the season's demand of the trees, thus leaving little to wash out during the winter and spring. The application is to be made in the spring, to supply the small loss that may have occurred, and give the trees growth when they most require it, and afterward sustain the fruit growth.

The healthiest of all soils is a sandy soil, growing the healthiest wood and fruit, and adding to the soundness and flavour of the latter, secured, no doubt, by the more ready admission of fresh rain water and air.—*Queenslander*

BABUL BARK.

TO THE EDITOR OF THE PIONEER.

SIR,—A number of your correspondents have written about *babul* bark. One states that it would be expensive to separate the seed from the pods. Might I ask how do we separate bran from flour? The Bombay Forest Reports put the cost of separation at R7 per ton. Another correspondent declares that the Bombay tanners have to import oak bark, therefore oak bark must be better than *babul* or wattle bark. Why the tanners at home, who it is presumed know their business, import *acacia* bark at £16 per ton, and they will only pay £7 per ton for the best English oak bark. Brown's *Forester* gives minute directions for stripping bark. Cost at home with labour at 2s. 6d. per day is put at £2 per ton; here cost with labour at three annas should be at about R12 per ton for an article worth about R120 in Bombay. If Major Stewart would tell us a little of what he knows on this subject, it would be a great help to those who propose speculating. I habitually use shoes and slippers made of babul-tanned leather, and they wear better than Mr. Waukenfast's at any rate.

CHARLES W. MCMINN.

MANGO CULTIVATION.

TO THE EDITOR OF THE PIONEER.

SIR,—The *Englishman* of September 13th contains a notice of a proposal of Dr. Bonavia of Etawah regarding the formation of an Imperial Mango Society. Your contemporary details what ought to be the aims of the Society. As, doubtless, very many are interested in the cultivation of mangoes, it will perhaps interest some of your readers to know that many of the suggestions put forward by the Calcutta paper have been taken in hand by Mr. Maries of the Durbhanga Raj, who has been closely studying the subject of mango culture, has pointed about 200 varieties, and has, with the sanction of His Highness the Maharajah of Durbhunga, commenced an extensive mango orchard or garden which will contain careful selections of the very best varieties of early and late mangoes. Mr. Maries expects to be able by careful selection and cultivation to prolong the mango season from May to October, and hopes to be able to supply fruit even later. This orchard, though planted for the use of His Highness the Maharajah, is intended as a model for growers of this fine fruit. Mr. Maries has, I believe, in hand a catalogue of the finest varieties which he contemplates publishing for general reference, as well as a manual for mango growers, which will contain not only valuable information collected by Mr. Maries, but the result of his own observations and the experiments he has in view regarding improved cultivation, &c. As the

Englishman seems to consider its suggestions original, I should like you to publish this letter, as the credit of originating the scheme noticed in that paper is, I should say, entirely due to Mr. Maries, who has accomplished much that has been suggested by your contemporary, and who is well known as a lover of plant-life and a plant collector in Japan and elsewhere. SILEX.

TEA IN INDIA.

In noticing the Deputy Commissioner of Cachar's remarks on tea, a contemporary says:—"It is evident to us, Mr. Knox Wight has not studied his subject with sufficient care to submit an opinion that in the mind of a practical planter would be likely to carry much weight. Whether cost of merely manufacturing leaf be considered, or of cultivating plant to produce that leaf, matters very little as a basis of reckoning cost of production. We do not care about going into items; all we need concern ourselves with is the rate at which tea, manufactured and ready for use, reaches the auction room or warehouse for sale—allowing a small margin for agency charges—small in appearance, though actually and proportionately out of all symmetry with other charges and costs, and therefore a heavy burden on the producer. That, however, we may leave for the present and return to our criticism. Whether we take him in the abstract or as merely setting up a theory without foundation, we can easily perceive that Mr. Wight has not made the tea plant, or tea production, a subject of much study and calculation. We maintain that a garden averaging three maunds per acre *may* be made to pay, under favorable conditions, and of these conditions Mr. Wight apparently has no knowledge. There are gardens and gardens. We repeat—given certain conditions—and three maunds per acre *might* pay. What would be said of a three-hundred-acre garden with nothing in it but Munipore and Cachar indigenous, Assam hybrid, and such teas, fetching nothing under one rupee per pound? That is to say, three hundred, multiplied by three, multiplied by eighty, or a total of R72,000 per yield. It may be averred, and we should have to admit the fact, that no garden *does* produce anything like this in quality of leaf. Very true, but that does not detract from the virtual strength of our contention that it *may*. Then, again, Mr. Wight is perfectly wrong in his intimation as to the delicacy of tea as a plant. It is commonly known that there is hardly a product-yielding bush known so hardy, so capable of resisting deteriorating external influences. Moreover, it is admitted that even in cases of fire—and a more destructive agent can hardly be conceived—tea bushes that have been scorched almost past recognition, have revived and yielded as plentifully as ever. Mr. Wight tells us, possibly in jest, that danger lurks in the course adopted by planters "to discard Chiua tea and to plant nothing but high-class, free-yielding plants." Where that danger is to be discovered, or in what manner avoided, he does not condescend to explain, nor would his readers be greatly edified if he made any such attempt. What can be the object of telling practical men, who understand their business thoroughly, that, although they are adopting the very best means to improve their gardens, to raise the value of their manufacture, and thus to defy competition, they incur a certain undefinable danger, which has provisioned itself exclusively to the Deputy Commissioner of their district—who conceals it from them—esteemed and popular as he was known to be? Mr. Knox White is unquestionably a man of ability, but that ability will not enable him to blind the tea planters of Cachar, who, as a rule, we venture to guess, are a little too far north for him.—*Indigo and Tea Planters' Gazette.*

PALM NOTES FROM THE SYDNEY BOTANICAL GARDENS.

However grand tall gigantic palms may appear, no one can gainsay that the early life of these wonders of vegetation is the most picturesque and the most pleasant to behold, as when in this state they are generally either possessed of pretty short stems with surmounting head of handsome leaves, or have dense foliage to the ground level; whereas with aged plants a plain bare trunk with leaves too high to be gazed at pleasantly is all that can be observed. Knowing the palms in our Botanic Gardens some quarter of a century ago, when they were dwarfs, we somewhat now miss the beauty they then presented. For decorative purposes, and apparently at home anywhere, the chamærops palms give very pleasing effects. C. Fortuni and C. excelsa are remarkable palms, with fair stout stems well clothed with black fibrous material; the main difference between the two is that the leaves of Fortuni are rather smaller than excelsa. The others, as C. tomentosa, C. macrocarpa, C. Martiana, and C. humilis, a goodly collection by-the-way, stool well from the ground, and form very handsome dwarf fan-leaved palms suitable for almost any climate, providing they are not cut about with harsh winds. The situation they are growing in in the Botanic Gardens is certainly not one of the best, as the soil is a poor sandy loam unfertilised. What they would be in good rich land we can only conjecture. The sabals, which in infancy are not very attractive, form very handsome fan-shaped leaves on long stalks as they get aged a little. There is a great family likeness amongst them, and can be easily recognised. The species worth noting and examining are S. umbraculifera; Sabal palmetta, very curious by its dead leafstalks interlacing each other, thus forming, as it were, a natural plait up the stem; the other is S. Mexicana, specially noticeable for its fine fan-shaped leaves. The genus Phœnix, to which the tree date palm belongs, furnishes generally tall specimens. P. farinifera, or small date palm, has a very tall, gracefully curved stem, as usual surmounted with its head of foliage and fruit. Phœnix sylvestris is very picturesque, as presenting to the eye great girth of stem. The dwarf species, at least at present, are—P. rubra, a Cape of Good Hope species, stooling very freely, and P. paludosa, presenting a somewhat similar appearance. The Cocos genus are represented by C. plumosa and C. flexuosa, both very tall trees. Other wonders of the palm family consist of Copernica serifera, a handsome black stem, fan-leaved palm, stooling very freely; Diplothemium maritimum, with a gigantic stem and pretty drooping fronds; the monster stemmed Jubea spectablis, with its rigid leaflets; Arica Madagascarensis, a stooling palm, towering up to a great height; Caryota urens, with its curious leaves; our native Seaforthia elegans; the thatch-palm of Lord Howe's Island, Kentia Forsteriana, as handsome as the best; the wine-palm, Elais; and as a minnow amongst the tritons our native walking-stick palm, Arica mononstachys. The above form the palmetum near the entrance gates to the Garden Palace grounds, and the only fault with the collection is that they are too much crowded, a pardonable one, however, considering the length of time it takes to bring them to such a condition.—*Sydney Mail.*

CHEAP FENCING.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—I note in your issue of August 23rd, a letter signed "Cheap Fencing," asking for descriptions of fences and their cost. I am unable to give cost of materials in this colony, but, having lately come from Queensland, where a great deal of "barbed" wire is used. I can say that a barbed wire strengthens a fence 100 per cent, as no stock can lean on it to reach anything on the other side, by which they break wires, and then get out. I know fences of six barbed wires that stop all kinds of stock, even dogs, goats, and pigs, and in the big fences erected to stop kangaroos and dingoes barbed wires are put in, above the wire netting, and when the former jump the wire, which is 6 ft. 6 in. high, some of the barbs catch in their skins, rending them down so that they generally die, often not going 200 yards from the fence. I have been surprised to find that the barbed wire is £10 per ton more here than in Queensland.

"Cheap Fencing" will find that the old tedious and difficult way of repairing broken wires is got over by the very handy tool shown at the recent agricultural show, for holding the broken ends, and straining them together at the same time. As it weighs only about 5 lb., it can be easily carried.—Yours, &c., FENCER.

"PRICKLY PEAR" IN QUEENSLAND.

TO THE EDITOR OF THE AUSTRALASIAN.

SIR,—I have been struck by the reference in your "Rural Topics and Events" column to the abovenamed plant. Can you tell me if it is a native plant? My reason for

asking is that in America this is the common name given to the cactus plant, and in Mexico the "nopal," or cactus plant, is highly esteemed as food for sheep in times of drought; in fact, a Mexican shepherd thinks no pasture good unless it has an abundance of nopal thickets upon it. He will shrug his shoulders contemptuously, and tell you that a piece of country, possibly very beautiful in appearance, is "only grass land." Every Mexican shepherd carries a long sword-like knife, with which he slashes off a piece of the plant as he passes, so that the sheep can make a beginning upon it; then, I have been told, in spite of the prickles, they will eat it to the last blade. In fact, I have been told by men of experience that when pressed for food sheep find a means of breaking in upon the plant themselves—but, of course, they have first to be taught that the plant is good for food. They are put upon it to fatten, and require no water while fed upon it, even in the hottest months; indeed, they are thought not to fatten so well if they have access to water while being fed upon the nopal. Working bullocks I have frequently seen fed upon the plant. It is cut down and held for a few seconds in the flame of a blazing fire, when the prickles are so destroyed that cattle can eat it, and eat it they do greedily, standing round the fire waiting for it to be thrown to them. If it is this plant that has found its way into Queensland it may prove to be not altogether an unmixed evil. The greatest drawback that I can forsee would be the prickles getting into the wool. There are so many varieties of the plant, too, that are useless as food for stock; but the only variety I have seen in this country, having an oval, round, or egg-shaped fleshy leaf, if leaf it can be called, is precisely, to the eye at least, the same as I have seen working cattle fed upon in Mexico. I was told that sheep do not care for the younger shoots, and will leave the growth of the year untouched, feeding only on the older portions of the plant.—I am, &c., BUCOLIC.

POISONOUS VANILLA.

The manifestation of symptoms of poisoning in upwards of one hundred residents in Brooklyn (*Lancet*, September 6, p. 441) after eating ice cream flavoured with natural vanilla recalls a similar occurrence in Vienna in 1873, the report upon which by Dr. Rosenthal (*Pharm. Journ.*, [3], iv., 838, 852), although it presented no satisfactory conclusion, may be advantageously referred to. The symptoms observed in Brooklyn were practically the same as those in the Vienna cases, consisting in severe pains in the hypogastric and epigastric regions, with violent vomiting and purging and in many cases serious collapse, accompanied by blueness, coldness and shrinking of the skin, like that observed in cholera. At first the blame was thrown upon copper derived from the vessels in which the cream had been prepared, but an examination of these showed that the tinning was continuous, whilst no metallic or other poison was detected upon chemical examination. Dr. Sizer, who reports the case, evidently suspects a formation of "ptomaines," consequent upon the decomposition of the cream before freezing, principally on the ground that a fetid odour was noticed during the analysis. But the cream used for the noxious product had come from two out of twenty-seven packages, none of the remainder of which is known to have produced injurious effects. In Vienna the same suspicion was at first entertained, but was put out of court by the fact that several persons who suffered had not partaken of a cream compound at all, but of a farinaceous dish flavoured with vanilla. Moreover, the cream theory is hardly consistent with the experience that these poisoning epidemics, of which there have now been several, do not occur in connection with the eating of cream ices other than those flavoured with vanilla. On the other hand, rightly or wrongly, vanilla pods are widely credited with occasionally possessing poisonous properties. Dr. Rosenthal mentions a case where a confectioner in Altona, having been compelled to give up his business in consequence of some persons being poisoned by vanilla cream ice supplied by him, disposed of his stock of vanilla to a confectioner in Bergen, where the ice made with the pods also proved to be poisonous. In the paper on "vanillism," occurring among persons employed in handling vanilla *Journ. Phar. Chim.* [5], x., 35), which has already been referred to (before, vol. xiv., p. 423), Dr. Layet avers that vanilla ingested into the system sometimes acts as a true poison, and he associates this character with an inferior variety called "vauillon," the pods of which are free from rime, soft, viscous and nearly always open. He also gives reasons for believing that the mould occurring on the pods is sometimes poisonous. The unfavourable reputation of vanilla has also made its way into the text-books, where the steeping in cashew-nut oil and the methods of drying have been variously credited with the mischief. It may be added that according to M. Jaillet, in the Island of Réunion, the tree yielding the "purging nut" (*Jatropha Curcas*) is frequently used to support vanilla creepers, and it has been pointed out in this Journal (xi., 430) that there is nothing improbable in the occasional absorption of the acrid juice of this euphorbiaceous plant to an extent sufficient to affect the vanilla.—*Pharmaceutical Journal.*

LECTURE ON THE JOHORE FORESTS.

Mr. James Meldrum, F.R.G.S., Commissioner to the International Forestry Exhibition from his Highness the Maharajah of Johore, delivered a lecture, entitled: "The Johore Forests." Mr. Jack, Commissioner from New Brunswick, occupied the chair, and introduced the lecturer. Mr. Meldrum began by stating that Johore forests were situated on the Malayan Peninsula, at the extreme south of the Asiatic continent. The territories of Johore, Maur, and their dependencies consisted af about ten thousand square miles. For a tropical country the climate of Johore was exceedingly healthy, the thermometer averaging about 78 degrees in the shade. This lowness of temperature was no doubt owing to the vast forests of the interior, which attracted the rain-clouds and retained the moisture, so that when the wind blew over them the breezes were comparatively cool. No epidemics, hurricanes, or cyclones passed over it. Nearly the whole of the interior of Johore was dense virgin forest, and as there were no roads beyond a short distance from the seaboard and from the banks of the rivers, there was no likelihood of the wealth of timber now locked up being available, as it was well known that timber beyond a certain distance from water carriage would not pay the expense of cutting and haulage. Specimens of 350 kinds of Johore wood were in the Forestry Exhibition. The useful kinds were extensively used for local works and for exportation—China, India, and Mauritius being the principal markets; but considerable parcels were sent to the Dutch colonies, Batavia, and other parts of Java, and to Sumatra, to Australia, and to New Zealand and other places. Little had been sent to Europe as yet, the difficulties being the price of freight and prejudice against using a new kind of timber. Sooner or later a trade would be done in some of the best kinds, such as ballow (sometimes called Johore teak and camphor wood), both of those sorts having been admitted by Lloyd's for all parts in ships of the highest grade. For purposes where great strength was required the first was excellent, and for durability the camphor wood was not to be surpassed. Mr. Meldrum thereafter gave a detailed description of the various kinds of wood found in the Johore forests, and referred to the ravages committed by the sea worm and white ant—the two chief agents of timber destruction in the tropics. Johore steam sawmills were situated at the edge of what was once a dense forest. Now all around was clear, and the town of Johore Baru was becoming quite an important little place, with its streets of brick and tiled houses, inhabited principally by Chinese and Malays. These mills were established in the year 1860, and had gradually increased their plant, until now they might be pronounced the most extensive concern of the kind in Asia. His Highness the Maharajah of Johore gave facilities and encouragement to a few private individuals to set them agoing, and from their foundation up to the present time large quantities of manufactured timber had been shipped to China, India, Mauritius, Java, Ceylon, &c., besides supplying the local demands. Roads, and especially a railroad, were what was needed in Johore, and nowhere could they be construct d cheaper. The Maharajah would give all assistance, labour was cheap and so was wood, whilst land could be obtained on easy terms. By opening up Johore, Singapore trade and commerce would benefit. The accomplishment of this was only a matter of time. His Highness the Maharajah was an enlightened

Prince, anxious to do all he could for the advancement of his people and country. Under his mild but firm rule great strides had been made, and doubtless there existed a great future for Johore. On the motion of Mr. Jackson, Kew, seconded by Mr. Dunn, a vote of thanks was awarded to the lecturer.—*Edinburgh Courant.*

ON THE COST OF OPENING LIBERIAN COFFEE LAND.

TO THE EDITOR OF THE NORTH BORNEO HERALD.

SIR,—I see by your last issue a note on the cost of planting Liberian coffee land, and as it may be of interest to your readers to know what the same costs in Ceylon, I beg to offer you an estimate made out in Ceylon money, *i.e.*, rupees and cents, and as done in that country. I wish to state that my object more especially is to prevent people who have no experience in planting matters from being misled by estimates that are far too low, and I would point out in the case of planting, that as a "thing of beauty is a joy for ever," so is a well-planted estate. I do not deny that good forest-land could be destroyed for the price your correspondent makes out, but from experience dating back from 1874, I am quite sure no land could ever be made into a respectable property at the prices put down, and I would strongly urge any intending investor not to waste $20·50 an acre in land devastation.

My estimate, it must be understood, is only for opening land, and not for bringing it into bearing, which is a very different thing, and I may further add, that as machinery here would cost more than in Ceylon, the total expenditure under that head would be proportionately greater.—Yours, &c.,

F. L.

ESTIMATES FOR OPENING 100 ACRES LIBERIAN COFFEE.

	R.	c.
Felling and clearing 100 acres at R18 per acre ...	1,800	0
One set of lines containing 20 rooms each 10 feet by 10 feet, mud walls and shingle roof at R40 per room	800	0
Lining, 8 feet by 8 feet=679 per acre or 67,900 pegs, and as a cooly can cut 1,000 a day at 35 cents=R23·80 to make. To put in costs R3 an acre	323	80
Holing, each hole 18 in. by 18 in. by 12 in. at the bottom, a cooly will do 50 a day or 1,340 coolies at 35 cents=R469. One axeman to 10 to cut roots=134 axemen at 35 cents=R46·90. One Kangany (mandore) to 20 men=67 at 35 cents=R23·45	539	35
Filling costs half the cost of holing	269	68
Plants (if bought) cost R15 per 1,000=R1,020. A cooly will hand-plant 300 plants a day, 223 at 35 cents=R78·05. One Kangany to 10 men R7·70	1,105	75
Shading costs about the same as planting, say ...	80	0
Roads 2½ miles. A cooly cuts 22 feet of ordinary earthwork in the solid, R210. Cutting logs and stumps with mandore R105	315	0
Draining to be added to latter, or R10 per acre...	1,000	0
Management for 6 months at R120 a month ...	720	0
Bungalow of two rooms for manager with cook-house...	300	0
Weeding for 8 months at R1 per acre	800	0
Contingencies, Medical and Miscellaneous at R2	200	0
Total per acre R82·53½...R8,253	58	

Or at the present rate of exchange in Singapore dollars and cents (R226 for $100) $36·51 per acre.

Note.—In the above estimate I must call attention to the following:—

I.—In the holing, 900 holes are not estimated for as falling on waste ground.

II.—In planting, no allowance has been made for transport to the estate and to the coolies in the field.

III.—In roading, no consideration is taken of blasting or stone work of any sort if necessary.

IV.—No cost of supplying dead plants is calculated which might be stated at 25 per cent on cost of planting.

V.—The management is only estimated for six months for an assistant with no successor after that time, or salary to an agent over him.

VI.—Medical assessment (on an average 75 cents per acre), is not considered, nor the item of tools—a high one.

VII.—Coast advances for procuring labour is also left out, so that taking these further items into consideration, the actual cost of opening 100 acres of land, without the cost of the same as purchase money, would, with experienced labour and great economy, amount to R120 per acre all round, and without interest of money. From what I see of Malay labour, the estimate would have to be increased to apply the figures to North Borneo.

GUM HOGG AND ITS USES.

Under the name of gum hogg, a substance is described, of which it is stated that the botanical source is unknown. It appears to be of a similar nature to tragacanth, taking up a large proportion of water, though it is not absolutely soluble. An experiment in this direction showed that, after being in cold water for twenty-four hours, it swelled up into a soft white transparent mass, occupying the lower half of the vessel in which it was placed; when agitated, the mass showed no disposition to form a uniform mucilage, but separated into small, soft, transparent and rather granular fragments resembling pounded ice; this subsided at the bottom of the vessel again when it was set at rest. A second portion of the gum, by prolonged boiling with water, gave the same result as obtained with cold water.

The commercial history of this gum in North America is very interesting. It appears to have been introduced into Salem, Massachusetts, about thirty years since. At that time Salem was the headquarters of the East India trade, and this gum came with a lot of tragacanth imported to that place from Calcutta. It was supposed that it might be used in place of tragacanth, as a cheaper article, by the shoemakers. It, however, came into the hands of a noted drug garbler of the place, and was rejected immediately by him as an inferior gum. It was next shipped to Boston for sale, and after a number of ineffectual attempts to foist it on the market, it was finally put up at public auction and sold for two or three cents a pound to one of the principal booksellers. The purchaser made a number of ineffectual attempts to utilize it for different purposes, and finally, somewhat disgusted, placed it in the hands of a chemist in the neighborhood of Boston; he made several experiments with it, and discovered its property of forming a non-adhesive mucilage, when boiled with an alkali. It was soon after utilized for the manufacture or marbled paper, which was just then becoming know in the country. Gradually the secret became known, and as there was a slight demand for the article at different times, small lots were brought into this country. Up to the time of the experiment being made the gum had received no name, but afterwards it was known through the trade by that of gum hogg, and it is believed that name was given it by Prof. Jackson, on account of its obstinacy in resisting the different efforts for its solution, and thus behaving like a well-known animal of similar perverse and willful habits.

Of late years the gum has gone considerably out of use on account of the irregularity and scarcity of the supply. The process in which this gum takes a part in the manufacture of marbled paper consists of staining the paper and the edges of books in a variegated manner. The gum is first allowed to soak in cold water until swollen, and then boiled with a weak solution of pearl ash until a thick consistent mucilage is obtained, which is strained. This forms the basis or vehicle for receiving the colors and transferring them to the paper, and is placed in a shallow tank about five feet long, three feet wide, and four inches deep. This body must be removed as often as fermentation in the mucilage renders it liquid. In cold weather this is not so frequent, but in hot weather it must be replaced with fresh at least twice daily. The colors used are the ordinary paint colors ground to a cream with thin mucilage of gum arabic. The workman standing over the tank first takes a large brush with spreading bristles, and dipping it in his color, sprinkles it over the surface of the tank by twirling the handle between his hands. The value of the mucilage is now shown, for the colour does not either mix with it or spread over its surface, but retains the circular form the drops would assume upon first striking

a plane surface. The first colour is then followed in a similar manner by a second, using a fresh brush, and thus in turn by a third, and so on, at the pleasure of the operator, each particular drop showing no disposition to mix with its fellow. The pattern thus made is mostly of round drops, but should it be desired to vary it, combs of different degrees of fineness are drawn in different directions gently over the surface of tank for a few seconds, where the colour is transferred from its surface to that of the paper, and after being hung to dry, is burnished by hot steel rollers: no particular quality of paper is needed, the only requisite being it should not be too highly calendared. A smooth piece of board is now drawn over the surface of the tank, when it is ready for a fresh operation. The edges of the books are stained in a similar manner, the book being taken unbound and pressed between boards tightly together, so that none of the color shall penetrate beyond its surface; they are afterwards, when dry, burnished by a hot iron tool by hand. The products afforded by the process are of infinite variety, and, as can be imagined, no two products are ever exactly alike, and, by varying the colours, an almost endless kaleidoscopic change can be produced—*Oil and Colorman's Journal*.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, November 1st.

It is a fact well-known to all gastronomists that the flesh of wild animals, is more delicate and savoury than that of the same species domesticated. Two causes produce this difference: first, limitless liberty; and second, a greater range of food from which to select. Now, this difference is not the less sensible with respect to the animal's hair or fleece; and the fact was shrewdly noticed in Spain from an early hour in the production of beautiful wool. It was thus the association known as the *Mesta* was founded. It was composed of the grandees, the influential monasteries, and other rich landowners, who became the joint-owners of those immense flocks of nomadic sheep, which incessantly travelled from province to province, in an order most favorable to the seasons. In consequence of these migrations, the sheep enjoyed the same liberty as if in a wild state, and their fine wool rapidly became famous. The flocks thus united were called *Merinos*—hence the origin of the name; they were also designated *transhumantes*, because they voyaged in summer up mountains, and in winter in the valleys. Each flock was a subdivision of the *mesta*; there was a superintendent on horseback for every 50 shepherds: he directed all movements, selected the most grassy routes; he was besides a veterinary surgeon. The shepherds on setting out as well as on returning, received an indemnity; in addition, they had 2 lb. of bread daily, independent of their wages.

M. Rouvière is the founder and propagator of green fodder in stacks in the open air, as M. Goffart is the apostle of ensilage. The plan of M. Rouvière has the important merit to cost nothing; and, therefore, there can be no excuse for not giving it a trial. And those who intend adapting ensilage would be wrong to lay out money in constructing trenches before having tested the Rouvière system. The chief difficulty in the case of the latter, is the difficulty of keeping the stack from inclining if the work-people are at all inattentive. M. Rouvière builds his stacks rectangular pattern, with three stakes driven into the ground on each side to guide the laborers, and which are ultimately pulled up. The stack is built to eleven or twelve feet, and the maize tipped from the waggons, on each of the four sides in rotation, to prevent the stack from taking a lean. M. Rouvière now recommends the employment of increased weight; instead of 16 cwt. per square yard, he adopts double that pressure, and in regular instalments of 6 cwt. daily. Thus he can correct any oblique tendency of the mass. His beet-leaves were preserved in this manner, equally as sound as his unchopped maize.

A farmer writes that his fields were invaded by couch grass. He got rid of the terrible enemy in the following manner:—Plough in autumn at a uniform depth, in spring harrow and plough again, repeating the process. The simple exposure kills the weeds. But the ploughings must take place in dry weather, and never harrow till proceeding to plough. A root crop, say potatoes, will enable what may remain of the pest to be removed. Keep a wide and clean open furrow between the headlands, and that nursery ground for the switch—the ditch.

Severe winters in France being habitual, do not allow of root-crops remaining on foot. The roots are generally stored in silos or pits. In case the latter exhibit indications of falling in, be sure decomposition exists; in this case open the trench, remove the sound roots to a shed, and make the new pit more secure. Where stored in cellars so long as the frost is not severe, let the air circulate freely. Some farmers leave the smaller roots during the winter into the soil in order to utilize their sprouts for ever in the spring. During winter German farmers give their horses—which are not the less fatigued despite the fewer hours of work—every week small portions of salt, mixed with oak bark, some juniper seeds, and wormwood reduced to powder. In Saxony, an excellent practice prevails, that of taking the chill off the water supplied stock; frozen water often can be dangerous for cows in calf. For milch cows that have to put up with a dry diet, meal drinks are ever supplied in a tepid condition; in the best dairy districts of Holland, Delft and Kampen, and even the once-celebrated Friesland, hay and linseed cake drinks constitute the chief winter feeding.

The beet-sugar factories are at full work, but complaints are general that the yield of roots has been inferior this season. Some fabricants are endeavouring to sell their sugar in the crystallized granular form, such as America presents her cane-sugar in the market. If the public accept the new fashion, the fabricants will economize something in expenses.

Touching the phylloxera, the insect continues to advance only the more slowly, as it marches to colder zones. The precautions to check its progress are severe, but it gains ground all the same. The vintage is terminated; the yield, save some local deceptions, has not been bad. Commerce is still slow to purchase new wines; however, some transactions for samples, under ten degrees of alcoholic strength, have been sold at 15 to 22 fr. per 22 gallons, above 10 degrees at 25 to 38 fr.

ALGERIA bids fair to become a great wine-producing country, for the area of its vineyards is increasing annually. In 1850 there were but 1,980 acres of vines in Algeria; in 1877 there were 33,520 acres. The area is now about 50,000 acres, with a production of 350,000 hectolitres of wine per annum. M. Leroy-Beaulieu, in his recent book on colonization among the Arab tribes, says that should the immunity from phylloxera which Algeria has hitherto enjoyed continue, it would not be surprising if in ten years' time there were from 375,000 to 500,000 acres of vineyard in the country, with an annual production of 150 to 175 million gallons. It is of course unlikely that Algerian wine will, at all events for a long time to come, take the place of any of the historic European brands; but it is probable that it has a prosperous future before it for labelling under other names which smell more sweet.—*Straits Times*.

RHEA CULTIVATION.—It is now about fifteen years since the Government of India offered R50,000 as prize for the best machine for extracting the rhea fibre. As those submitted for the trial did not answer the required conditions, the prize was withheld. Subsequent experiments were made from time to time and lately during the Calcutta Exhibition, but the results were doomed to disappointment. We now hear that the Gleurock Company of Southern India, who have plenty of capital to go upon, with such an able and enterprizing manager as Mr. Minchin, will spare no pains or trouble to render the experiment successful. From figures published in a Madras paper, it appears that £5 is considered sufficient for the upkeep. It is, however, not only necessary that the machine should be perfect in itself, but the rhea must be highly cultivated, in order to yield what is expected of it; it will require much manure, as it is an exhausting crop, but the market value being £30 a ton, a large margin is left to fall back upon. The process of cleaning, according to an estimate of Dr. Forbes Watson, will cost from £7 to £9 per ton. An acre of the plant will produce 10 cwt. of clean fibre per annum. This at £15 would not leave much profit. Cultivation per acre £5, cleaning say £4, would leave but little for freight and other incidental charges. The fibre to be profitable must give at least £30 an acre. —*Indian Agriculturist*.

PLANTING IN BRITISH GUIANA.

From Mr. Jenman's interesting Report as the Government Botanist and Superintendent Botanic Gardens, we quote as follows:—

The annual rainfall of this country is comparatively moderate for a region within the tropical belt, and it shows considerable uniformity from year to year. The mean for the three years that a record has been kept at these gardens, is only 86·79 inches, and it is an unusual circumstance for a greater quantity to fall in a month than fell last May (1882). Indeed, about that quantity occurs with a frequency approaching uniformity as the heaviest monthly fall of the year.

The heavy sugar crop of the colony last year, the largest it has ever produced, was due to a combination of circumstances, the principal of which appears to have been the making of dark sugar, and consequent reduced production of rum. Other factors more potent than the moderate character of the weather contributed to the result. How far it was due to favourable weather I have not the information to discuss. It would be difficult, however, to over-estimate the influence of seasonable weather prevailing throughout the year on the staple cultivation of this colony. The good or bad character of the year's rainfall depends, within a certain mean limit, not so much on its quantity as on the manner of its distribution. The best seasons are those in which the rainfall is most uniformly distributed, presenting the least contrast between the wet and dry seasons, and, in its diffusion, modifying both. Crops suffer from protracted drought while it lasts, but both ground and crops suffer from excessive rain, the influence of which upon the former can be but slowly corrected by labour and time.

Taking the last three years, and beginning with February, as January belongs to the winter wet season, the following table shows the rainfall for the successive seasons, the dry and the wet following each other alternately:—

	1880–1.	1881–2.	1882–3.
Spring ...	24·00 in.	10·58 in.	17·71 in.
Summer ...	25·24 „	29·95 „	36·73 „
Autumn ...	7·66 „	12·54 „	13·68 „
Winter ...	17·32 „	34·53 „	22·76 „
	74·22 in.	87·60 in.	90·88 in.

By thus following the seasons instead of the artificial arrangement which dates from the first of the year, a more just idea is obtained of the distribution and quantity of the years' rainfall.

A plant of the beautiful *Parkia pendula* of Guiana and Brazil, the Hippanai of the Indians of this Colony, which resembles so much in habit and size a Cedar of Lebanon or of the Himalayas, though it differs essentially and widely in its botanical characters, belonging in fact to the distant order Leguminosæ, was contributed by Mr. Alexander Winter of Berbice, who has since been good enough to procure a quantity of the seed for me. The Hippanai is one of the largest trees of the forests of tropical America, with a trunk four or five feet in diameter, and sixty or seventy feet high, above which spreads the dome-like, wide-reaching, head. I gathered last spring on the Berbice River a few seeds of what appears, though the tree was not in flower at the time, to be a second species of *Parkia* from its resemblance in growth and character, which have produced three or four plants.

COFFEE.—The large Liberian coffee plants in the nursery, at three years and a half old, have produced their first heavy crop of fruit, this being the second season they have fruited. The best bush yielded twelve hundred berries, but it is still thickly set with younger fruit in different stages of growth, as in fact, they all are. Some of the more heavily bearing bushes have not maintained their former healthy appearance under the tax on their energies imposed by production. Much, or nearly all, the foliage on the bearing branches has dropped away, while those bushes which are not in fruit, and those fruiting for the first time, when they bear only a few berries, are thickly clothed with healthy deep-green leaves. The branches I allude to are fruiting almost to their tips, and it must be remembered that it is characteristic of the common Arabian Coffee, too, to drop most of the foliage from fruiting branches. All the berries produced are being used for propagation. I mentioned last year having utilised the watery erect shoots which spring from the stem, and which if left alone absorb much of the vital force of the plant, by tying them out more or less horizontally on bushes which, from any cause, had grown up with naked or ill-furnished stems. The system has succeeded admirably, and the wood of these shoots, produced since they were cut back, conforms essentially in character to the wood of the lateral shoots, which is the normal fruiting wood of coffee. To carry it out, it is simply necessary for the pruner as he goes through the bushes dis-budding and removing these shoots, to take in his hand a bundle of pointed sticks about two feet long, with a hook formed by a spur of a branch at the upper end of each, and with these pin out, one by one, by inserting the sticks in the ground at a wide angle with the stem, the shoots required for the purpose. The bloom of the Liberian coffee opens during the night and dies away the next and following days. All the bushes in bud at the time burst into flower together, regardless of difference of age, the source from whence they came, or any other circumstance; so that, however widely separated bushes may be, they bloom simultaneously. The whole of a season's bloom of a bush is not, however, produced at once, but at short intervals of varying length between. This successional character must cause the plants to be in fruit all the year round. Some of the plants in the gardens exhibit a tendency to over-production, and consequent inability, observable in dry weather, to mature the whole crop under this periodical accumulation of fruit.

SUGAR CANES.—The different sugar canes procured last year, which had just begun to sprout when my Report was written, matured during the past autumn, and thus afforded an opportunity for their relative merits to be judged on the limited scale the small quantity of each kind allowed, which, however, to this extent, was fair, as it affected all alike. Six kinds were grown, but I have eliminated two—one, a white cane, on account of its short woody joints; and the other, a black one, for its slender habit, both in the size and quantity of the canes to a stool. The following are provisional names I have given them, chiefly after the countries from whence they were derived:—Hawaiian, Mauritian, Elephant, and Singapore Elephant.

The Hawaiian, which Mr. McCalman imported from the Sandwich Islands, where on the irrigated lava plains and valleys it is said to yield five tons of sugar to an acre, is characterised by its stiff, straight, erect habit, which marks the foliage as well as the canes. The plants were raised from single eyes, but averaged twenty ripe canes to the stool when cut, which shows that it is a good kind for, what sugar planters call, stooling, *i.e.*, producing many shoots from a root. This cane is of a dull straw colour, of the size and length of joint of the Bourbon, tho form a root. This cane is of a dull straw colour, of the size and length of joint of the Bourbon, the form commonly cultivated here. One of its advantages is that up to the time it is cut it remains perfectly erect. This character should recommend it for cultivation on the West India islands, where, by the frequently experienced gales, fields of Bourbon cane are often laid prostrate. It appears to ratoon freely (*i.e.*, shoot well from the root the second year), which is an indispensable character in a cane for cultivation. When ripe, twenty-one canes, all of an average stool, weighed 68 lb., and the foliage of the tops 13 lb. The latter is of a strikingly dark-green colour.

The Mauritian is a cane that has survived of a wardian case of different forms which I sent here some years ago from Jamaica, which were there derived, with many others, from Mauritius. It is a very productive kind, averaging twenty-five canes to a stool. It is fairly erect, but not stiff and straight like the preceding, and hardly up to the average of good varieties in height, thickness and length of joint. The latter defect is a disqualifying character from the manufacturer's point of view. Otherwise, on good land, it would prove a very productive form. It is a white, clear-skinned, cane. One stool, cut at the ground, of twenty-four canes, weighed 67 lb. and the leaves 11 lb.

The Elephant cane, procured from Barbados, is probably the true Elephant cane, which is said to resemble a Bamboo in habit and growth, and contains a moderate percentage of sugar. It is a large soft-fibred form, producing few shoots to a stool (only about a dozen), sub-

erect in habit, and of a pruinose colour. The cane is stouter, much. than the average of good kinds, but the joints are shorter. It did not arrow, but when mature the eyes sprang freely, and it retained to the end a raw unripe-like appearance. A large straggling stool of twenty-three canes, grown from several eyes, weighed 81 lb. and the leaves 17 lb.

The Singapore Elephant, derived by the Kew authorities from the Singapore botanic gardens, is a cane resembling in appearance and habit very closely the Bourbon cane. It produces an average of eighteen canes to a stool, which in the late months of their growth trail laxly on the ground, from which they curve upwards. They are a bright straw colour, turning ruddy on the sun-exposed side. The joints are long, and the canes are the thickness and length of the Bourbon. It is an excellent, heavy cropping, variety, but its sprawling habit would make a field of it an impenetrable thicket when mature. A stool of twenty-four canes weighed 72 lb., and the leaves 12 lb.

I have abstained from the expression of any opinion of the absolute or relative sugar-yielding merits of these canes, as I, a short time ago, furnished Mr. Francis, the Government Analyst, with samples to determine the quantity and character of the juice of each, which he has done. I believe, however, that he regards his apparatus as insufficient for the scope and accuracy with which he thinks the analysis should be conducted, and has therefore reserved the publication of the results for the present.*

Grafted mango plants are precociously productive compared to seedlings. Though some of the above are only three or four feet high, they have flowered already. I am also inarching some of the best East Indian and Ceylon kinds which I have raised from seed; and I am endeavouring to get together a good stock of seed of the Jamaica No. 11 to grow and treat in the same way. Though not strictly a short-fleshed fruit, in flavor I know of hardly any mango superior to this variety.

VANILLA.—A double row of Calabash trees (*Crescentia Cujete*) has been planted quite across the ground between the Superintendent's residence and the nursery proper, upon which to grow vanilla vines. The dwarf spreading habit, and soft moisture-holding bark, make the calabash one of the most suitable trees which can be used for this purpose, and its hardy character is a further recommendation. If all the Guiana species of *Vanilla* can be got together here, their merits can be compared one with another with facility, and determined. *V. palmarum* and *V. aromatica*, the latter one of the most beautiful of the Guiana orchids, have hitherto failed here through want of suitable support. The calabash trees will likewise be of service for the cultivation of other orchids, and of pepper, as well as vanilla.

COCA.—The coca plants (*Erythroxylon Coca*) have done fairly well here considering the low altitude, and how much above the temperature of the elevated region from whence the coca comes the normal temperature of this country is. The plants form rather slight, tallish bushes about five feet high, lightly clothed with the pale-green foliage, and they flower and fruit with moderate freedom. From the seed produced here, a good many plants have been raised, which I intend to use for its further trial. On the eastern slopes of the Andes the coca plant is cultivated at 5,000—6,000 ft. elevationin a moist equable climate.

CHERIMOLIA.—As I anticipated, the Cherimolia, another Peruvian plant from the same elevation as the Coca, appears with much probability unlikely to survive. The plants in the borders have died, though two or three kept in pots are still alive. Under more favourable conditions of shelter and soil it might bear open cultivation and survive for a time, but I have invariably found it to succumb at last to the temperature of a low elevation in the tropics. It has long been naturalised in the West Indies, where it thrives luxuriantly at from 3,000 to 5,000 feet elevation, and produces the most lucious of all Western tropical fruits.

Other economic plants of which the gardens possess few samples, but which are thriving satisfactorily are cinnamon (*Cinnamomum officinale*) the true cinnamon, which has grown well and flowered already; Pimento (*Pimenta vulgaris*) that yields pimento, now twelve feet high *Chavica Betel*, the green leaf of which is chewed by East Indians, covering a pellet made up of the betel-nut, lime and a third ingredient; *Wagatea spicata*, one of the richest tannin plants known, and, too, one of the handsomest flowering plants; *Carissa carandas*, a very hardy shrub, the fruit of which is largely used in India as a pickle. All the Anonas are doing well and fruiting freely, but the Cherimolia which I have mentioned. *Anona kirkii* is an African member of delicious flavour of fruit, but which fruit is useless through the little pulp it contains.

* Mr. Francis has recently analysed these canes again under better circumstances for a satisfactory analysis, and the results will be summarised in my forthcoming annual report. Note added 5th March, 1884.

ARECA-NUTS: A PROFITABLE INDUSTRY.

A considerable acreage is already under the nut on several properties here now. Personally I regard it as by far the best product for a man of limited capital to select, for, if funds run short, he can cease expenditure with perfect confidence that the plants, in any suitable locality, will reach full maturity in spite of prolonged abandonment, whilst for profits, unless you, sir, or any of your readers, can show prospects in this particular in a less favorable light, what other industry have we at present, or since the more hopeful days of cinchona, offering so good and withal sound expectations in the matter of returns? At 1,500 trees only, and an average not exceeding 200 per tree as the yearly crop, this may be stated as 30 cwt. per acre of nuts, *husked* and *cured*. As to prices, there is certainly a heavy difference for the several varieties, and unfortunately our Ceylon produce realises the least. The present market rates in India are for "Shiriwardhun" R40 per cwt. 1st sized, and R35 per 2nd sized nuts; next to which, selling usually at about half the above rates, ranks the "Mysore," probably including the Coast produce generally; whilst the Ceylon nut stands lower still at R12 to R18 per cwt. But even the small margin of profit on the latter, considering the capital outlay necessary, should suffice! Whilst at the price quoted for the firstnamed, equivalent to R1,200 per acre, I can only repeat the question—what other product have we that can hold a candle to it? It is true, tea claims the one advantage of coming into yield in 3 years as against 5 (and it is not improbable that the two products may be, to the best advantage, cultivated together), but with cocoa this is not so, and until some one can come forward and shew the reverse side forcibly, I must confess I would rather trust to 100 acres of arecas than the best 100 acres of cocoa in the island; and this without any disparagement, but fully recognizing the excellent recommendations of the latter. I firmly believe that no man with a limited capital, say of £1,000 or less, not desiring to incur debt, could find a safer, or a more hopeful investment for it. Though nothing more than due has been stated as to the fine crop of cardamoms on Udagama estate, and it may safely be hoped no doubt that many a fine return will yet be reaped in this neighbourhood, as elsewhere, from well-chosen fields of cardamoms, they can hardly be classed as in themselves a lasting product (will a cardamom field anywhere continue remunerative for over twelve years, or even *ten?*) or as a staple article of commerce; whilst tea and arecas, can, added to longevity of the plant, both claim their "hundreds of millions" of consumers. I should be less confident in speaking so decidedly in favor of "arecas" on the footing of an extensive industry, were it not that the conclusions come to have been invariably endorsed by, and to a large extent drawn from, data afforded by a number of intelligent natives, in positions especially entitling them to be able to speak authoritatively, several of whom are, in fact, themselves now going in extensively for the cultivation; and I am misinformed if amongst the latter is not to be included an employé long and well-up in the service of the Botanic Gardens, whose experience should not allow him to be at fault. I am either mistaking a "mouse" for "elephant," or the industry is especially deserving the attention of the planting interests at the present time. If there is a less favorable side to the picture, let us have it by all means, and the sooner the better. Till then, conjointly with tea, I can only continue to to regard "arecas" as the most profitable and sure cultivation we have for the moister portions fo the island, say at and below 2,500 feet elevation. The remark of a Mudaliyar in this neighbourhood, whose intelligence I have confidence

in, was "Establish an arecanut property, and it is 'a thing for ever,' falling nuts keeping up an incessant relay of trees!" Perhaps the new American dryer may be able to overcome the difficulty of curing Liberian coffee without deterioration, *in the husk?* If it is true the Americans are willing to pay a fancy price for the latter thus cured, it should be worth while trying to meet them. The inventers might do worse, on the strength of their professions, than test the machine for avery product here that requires to be dried.—C. R. —Local "Times."

THE COLLECTION AND PREPARATION OF INDIA-RUBBER: NEGROHEAD.

This Indiarubber may be looked upon as a variety of the Pará rubber, being in fact a modification in form only of the same product. It offers, however, a temptiug inducement to the collector for adulteration, and although in most cases it consists of the good, sound product of the *Siphonia elastica*, yet it is much to be feared that extraneous water and other plant juices find their way into the masses. Very frequently a mass of this rubber when cut open gives unmistakeable evidence of being filled up in its central portion with the liquid as collected from the trees. The bad smell of this rubber is due to the decomposition of the non-coagulable portion of the juice.

Good negrohead-rubber, when well washed, is one of the most useful kinds of rubber which we have; its rank smell being its only objection, exposure to the air removes a great deal of its bad odour. Its name has, no doubt, been suggested by the resemblance of a mass of it to the head of a negro.

It differs from the well known Pará bottle in not being uniformly coagulated in layers, but by accident or carelessness has become coagulated in the vessels in which it has been collected. It is a very common thing to find in a mass of this rubber a great number of small round flattened separate pieces about three-eighths of an inch thick, these have been produced by coagulating in the little clay cups used in collecting the juice from the trees.

Generally this rubber is much darker than Pará rubber, which arises from oxidation due to prolonged exposure to the air. There is no doubt that this oxidation tends to deprive the rubber of a considerable amount of its strength when worked up. A very light kind of this rubber is frequently met with, which is probably collected with much less exposure. The large quantity of negrohead rubber at present shipped from Brazil shows that it is now an intentional rather than an accidental production, and as it commands a good price in comparison with the bottle rubber and does not incur so much trouble and time in preparing, we can hardly feel surprised at the large supplies which are sent out. At one time it was suggested that the reason for not giving it the bottle form was from a scarcity of the palms yielding the nuts used in smoking the rubber. This is evidently not the case, as it is a very common thing to meet with Pará rubber in the bottle form dried without the use of these nuts.

The large quantities of negrohead-rubber at present offered would lead one to suspect that a reckless tapping of these trees is taking place, we can hardly imagine a cultivator whose interest is to preserve his trees so exhausting them as to be worth his while to convert the rubber into the negrohead kind.

If it should prove to be worth the cultivator's while to produce this kind of rubber than the bottle form, it may be of interest to see how far this mode of preparing may be improved so as to sacrifice the qualities of the rubber as little as possible.

Considering the facilities this kind of rubber places at the command of the dishonest collector and the comparatively small number of cases which are met with of fraudulent packing, we are tempted to believe that the Brazilian has not yet been educated in the vices of those countries which claim a higher standard of refinement.

We have no authentic accounts of other kinds of rubber being sent into this country from Pará, although it is well known that for some distance along the Rio Negro and the other northern tributaries of the Amazon, several trees are found which yield lactescent juices, which, when coagulated, have the appearance of good rubber.

A few years ago I brought from Pará a quantity of the juice of the cow-tree, which yielded a remarkably good rubber, quite equal in fact to the best kinds of Pará. I was told that the tree was too valuable for its timber to allow of its being tapped for rubber, whilst Mr. Green, H. B. M. Consul at Pará, told me that it had been collected and shipped as Pará rubber.—*Indiarubber and Gutta-percha Journal.*

THE receipts of rubber at Pará, in kilogrammes, for the first six months of 1884 were 4,914,516, against 3,926,000 in 1883, and 4,130,000 in 1882.—*Indiarubber and Gutta-percha Journal.*

SUGAR-GROWING IN FIJI.—The first parcel of sugar from the little Pioneer mill, which was removed from the Rewa to the Dreketi, has just been placed upon the local market, and has found a ready sale at £22 per ton. Seven tons were brought down. The quality was that known as "yellow counter." The proprietors speak very hopefully of the prospect. There is plenty of cane to keep the mill going for six months; it is yielding 10½ density, and as the produce is intended for local consumption, there is a good market. One of the anomalies of Fiji is that, being a sugar-producing country, sugar is here dearer than it is in Sydney or Melbourne. The industry is protected by an import duty of 1d. per lb; the miller therefore calculates at what cost the retailer can import, and sells at that rate, so that Fijian sugars have been selling to the local market at £42 per ton, which, when shipped to Melbourne, Sydney, or Auckland, would not fetch more than £32. The Pioneer produce is intended to bring this matter to its proper bearings, and therefore the mill has general sympathy in its favour, especially such as wells from the disinterested bosom of the thrifty housewife.—*Australasian.*

A CEYLON PLANTER'S LIFE IN TASMANIA.—The first year, as you know, I worked for X——, so I did nothing on my own account, but I left him last October at the end of the month, and commenced "scrubbing" for myself. I took down 12 acres in all, and felled some 20 to 25 large gum trees. Then I took ten acres to do for another man, and afterwards did two for X———. Not being flush of cash, I was obliged to get work, for I had but £30 when I started, and I had to pay £8-2-6 for survey-fees. This work kept me going until the time came for a burn-off. After the burn, I put up a loose box and commenced "picking up," which I finished in six weeks. Then I took work from X. ———— at 6s. a day for 8 hours of it, and used to get back to my hut about 4 p.m. After a mouthful of something to eat, I started sowing my grass seed until dark. As X. ———— had a house, I thought I ought to have one too, so I said to my other neighbour: "You want your land picked up now that the burn is finished; you, being a carpenter, help me to build a house, and I will give you the return help in 'picking up.'" So he did, and I am living in it now. I have two rooms 12 ft. × 12 ft., a kitchen 7 ft. × 12 ft., and a verandah 6 ft. at front and 7 ft. at back; also a small store-room. This winter I have "grubbed" nearly an acre of all the stumps (of course, not the large gum stumps, but all small ones), and just put in thirty apple trees, besides a quantity of others —cherry, currants, plum, gooseberry, &c. I have got in early potatoes, peas, carrots, turnips, lettuce, cabbage, and other English vegetable seeds. Before you get this I shall have put in a small quantity of oats for fowls, and have raised a large crop of potatoes to feed pigs upon and for my own use. I am now 'scrubbing' again. The grass I have, not being much, I am keeping it for seed, but I hope to be able to run a few cattle next year, if I can raise the coin to buy them. It's rather a lonely life, even after an Uva clearing. I generally spend Sundays with the Unwins, but the other six days I see no one, so work like a nigger to keep the blue-devils off. I do all my own cooking, cake my own bread, and do all my own washing, which is the roughest work of the lot. Few Ceylon planters would care for this sort of thing, for it is back-breaking work, and "grubbing" takes the softness out of your fingers and the straightness out of your back. But I like the life, and see a good good chance of making a fair living after a year or so. It is not a life I should recommend a Ceylon man to take. It is just the sort of work a navvy has to do, but one has no V. A. flying around to interfere, and, if one works, one can always make a living and an independence.—C. L. B.—Local "Times."

PLANTING IN JAMAICA.

(From an old Ceylon Planter.)

Blue Mountain District, Jamaica, 11th Oct. 1884.

Jamaica as most of your readers will know, is admitted to be the "Queen" of the "Antilles," though Trinidad and Barbadoes are Islands that in the way of prosperity seem now to be leaving their larger sister in the rear. Jamaica is not nearly as large as Ceylon, being but 144 miles long by 49 wide in the broadest, and 21 in the narrowest part between Kingston and Anotto Bay. In Jamaica, sugar is as much "king" as coffee was ten years ago in Ceylon; but there is at present a great depression, because of the low prices now ruling, caused by beet-root sugar competition, which is protected by Government bounties and, therefore, undersells cane sugar, though it does not possess as much saccharine matter. Indeed, it will be a sad look-out for the West India Islands generally, unless the mother-country obtain a favourable treaty with the United States, for the free admission, or best-favoured nation treatment for the importation of West India sugar, or so far condescends to depart from its free trade policy, as to place some restriction on the admission of bounty-grown sugars. I have always felt free trade was a mistake unless it was reciprocal, and thought it a great shame Britain does not foster and encourage her colonies, allowing their produce to come home free of duty, but imposing a small protective duty on the Imports from foreign countries, all of whom tax our productions. Surely, if free trade were such a paying thing, twenty years or more would have convinced other nations of its benefits; but it does not seem to have done so as yet, even in the vaunted republics of France and the United States. Another thing that has always astonished me is that England, which professes to have such a horror of slavery, should at all admit such products as slave-grown sugar and coffee, and thus be inconsistent in not favoring free-grown articles.

But to return to "Jamaica" it produces besides sugar, rum, molasses, coffee, pimento, coconuts, log-wood, etc., while the fruit industry has grown immensely within the last few years, and a large area of cacao is being planted, and will ere long become a very respectable item in the island export. As to the value of the fruit exported it has increased from £10,301 in 1874, to £154,246. These figures speak for themselves, and I am told that for small capitalists there is still a very good opening in the field of fruit production. Bananas are said to repay themselves in 18 months, but coconuts and oranges of course take longer in coming into bearing. A good deal has lately been said about the marked exodus to the Panama Canal works, but if times were good and prices of sugar remunerative, I do not think the sugar planters would suffer very materially, as they could afford to pay better wages: anyhow there were 13,245 coolies in the island on 30th September 1883, and since then a large batch of Chinese have been imported on trial. During the present year, 18 000 Jamaicans have left for Colon, and only 9,600 had returned to the end of September, but that is not so much out of a population of 580,000, at the census of 1881; moreover, the construction of the canal cannot last many years longer; as it is many who go, never return as they do from the effects of climate, and those who remain do not find it the "Eldorado" they expected, prices of provisions and other necessaries being exorbitant which runs away with the greater part of the higher wages. Of course, a few are fortunate and save money, but as a general rule most are like the boy who goes to sea for the first time, and often wishes to be at home again; so the Jamaicans must wish themselves back at their old work on the sugar estates, and enjoyment of their own huts and family life.

As a colony Jamaica is still a long way behind Ceylon in many respects, though it is the oldest of the British Colonies. This is no doubt attributable to the curse brought upon it by slavery, and the negro race being less energetic and intelligent than the Indian. As a city Kingston is a long way behind Colombo, though it has many natural advantages and has one of the finest land locked harbours in the world, the far-famed "Pallisadoes" forming a natural breakwater some six miles in length. The streets are disgracefully kept, but at length they are a beginning to reconstruct them. There is now next to no drainage, though water is laid on from the adjacent hills. The buildings and shops are poor, though the fire has been the means of getting better ones erected, and it is a pity the authorities are allowing many of the roofs to be "shingled" though a byelaw has been passed forbidding it.

At Spanish Town the old capital, the Government buildings are large, handsome and substantial: it would undoubtedly be the finest town in that respect for the seat of Government, the Legislature, and the public offices; but Kingston is cooler, healthier and nearer the sea, and seems to be preferred; there are yet a few who still contend for the removal of the Governor's headquarters to Spanish Town.

This reminds me to mention that our new Legislative Council, the unofficial members of which have been elected by the people, has commenced its first session, and the Council as reconstructed, is now at work. The *elected* members seem determined to give the Government no peace in the way of questions, about retrenchment, economy and reduction of Establishments. Many of the *pucca* Europeans or "Buckras," as they are called here, were quite content with a Crown Government and a Council such as you now have in Ceylon, but the "Brown" population (Burghers of Ceylon), and the Jews of whom there is a large element, agitated, and were backed up by the newspapers, to have back again the Constitution they lost after the Rebellion of 1865; and Lord Derby at last yielded in so far as giving them nine unofficial members representing the various island parishes as against six official,—power, however being reserved to the Governor to elect additional official members in case the *elected* members refuse to pass any measure the Home Government may deem of paramount importance to the well-being of the kingdom or the island. But in matters of finance and regulating expenditure, the *elected* members will have a decided majority, which is what they had been clamouring for: and yet they are not content, but like "Oliver Twist" want more, in the way of further extension of the franchise; but I hope it may be withheld until the Creoles, as they call themselves, are fitted for the suffrage. W. S.

PLANTING NOTES FROM UVA (CEYLON).

CROPS—COFFEE PRICES AND CURING—AN ESSAY ON CURING WANTED—WESTLAND'S SIEVE PLATES—THE NATIVES OF UVA AND NEW PRODUCTS.

Haputale, December 7th.

The total rainfall up here for last month was about 16 inches—not very much over the average of former years has fallen to date, though occasionally the fall has been very heavy, that of the night of the 16th November being the heaviest rainfall known for many years back. Since beginning of December there has not been much rain, but the temperature and fall of the thermometer has been very perceptible, sometimes as low as 52° at night. Gathering of autumn crop has been proceeding briskly, the earlier samples contained much light and deficient beans, but the later pickings have improved in quality. Spring crop on the higher estates promises to be particularly good; the best crop of many seasons past will be picked in the spring of '85 for the sale of which it is to be hoped prices will continue rising

in the London markets. In respect of coffee prices in the home market, I have heard much comment at various bungalows about the great discrepancy of prices realized in London for various estates coffee from this district, particularly about the fine figures. Kelburne Estate coffee realized above that of the neighbours (see price list in November number of *Tropical Agriculturist*) and I heard said, that the "Laird of Kelburne" attributes these fine prices mainly to the superior curing and preparation for shipment of his Agents in Colombo, Messrs. Baker and Hall, who, he declares cure his coffee *fifty cents* per cwt. cheaper than any other firm in Colombo and, that ever since he changed his Colombo Agents his coffee has been realizing from 7·50 to 10 rupees more per cwt. than he used to get for it when he cured elsewhere; if this is the case, some firms must be curing crops very negligently, hurrying shipments and not be giving sufficient attention to good curing and preparation in Colombo. Certain it is that the discrepancy of 20 to 30 shillings exists in the prices realized for coffee from estates equally as good, well cultivated, with equally good soil, the same elevation and aspect as Kelburne, and yet the prices realized are remarkably different which any person can see by looking over the price list in your *T. A.*

Mr. Westland's new Sieve Plates are highly spoken of as reducing the tail coffee to a minimum percentage and are being very generally adopted in place of the old sieve plates. While estates are looking in prime order I am sorry to say white and black bug have been very prevalent recently, especially on estates at higher elevations; leaf disease is much less prevalent but the pest is still among us, though in much less quantity than formerly. Native coffee is not quite extinguished, but wherever it has not been "rubbed out" and the gardens are kept in order, crops are good and the bushes bearing very well in many places, particularly in the rich valleys about Udakinde, Haputale and the Mahapalata generally. Government, I am sorry to say is not, as far as I can learn, doing anything to encourage the natives to adopt "new products," but he has been most industrious in collecting revenue poll-tax and paddy-tithes. Some irrigation works or dams for retaining water were attempted near Wellemada, but all have been washed away by the floods and a great deal of money and labour lost. Except Mr. Sharpe, I never heard of any other Assistant Agent in Uva ever attempting to encourage the natives in cultivating new products, new paddy cultivation or anything else. The Forester's berth in Uva is a sinecure, and now that minor roads are almost a thing of the past, this officer has little to do, and he might well be employed distributing tea, cocoa, cardamoms and other new products amongst the natives, as well as encouraging them to plant indigenous and foreign forest and fruit trees. Dr. Trimen proposed having a branch Botanic Gardens at Badulla, and, I think procured a grant, but I have heard nothing more about it.

As I mentioned before in my previous notes, tea is getting a fair trial on many estates up here; on some places wind blown and shuck coffee is being taken out to make room for tea and on some estates tea is being planted amongst coffee and cinchona, which I do not think fair to the new, product tea. If it is to succeed give it a fair trial on good soil, but do not handicap it by planting on land that has other products growing on it or on worn out old coffee fields. J. A.

VEGETABLE CURIOSITY.—A bringal (egg-plant) has been sent to us, which has four smaller fruits growing out of the portion next the stalk, "five-in-one" as the Tamil conductor of an upcountry estate calls it.

CONCENTRATED SOLUTION OF CINCHONA.—We learn that the Surgeon General with the Government of Madras recently brought to the notice of Government that the use of crude Cinchona bark in hospitals, suggested by the Director of Government Cinchona Plantations, is very wasteful and expensive, owing to the fact that infusions and decoctions soon spoil in this country. He suggested therefore that a concentrated solution of the various active principles in Cinchona bark could be prepared in this country, so as to keep good for any length of time in hot climates. A further report on the subject by the Director is awaited by Government.—*Madras Mail.*

PLANTING IN SOUTH INDIA.

SOUTH WYNAAD: VYTHERY, Nov. 21st.—The improvement in the price of coffee, although nothing very great, and the fact that we are picking what promises generally to be a fairly good crop, have somewhat raised our spirits. Another hopeful sign has been a visit from the representative of one of the Coast firms, with apparently a large commission to buy coffee. This gentleman is at present offering R29 per cwt., and has not, I believe, so far, found anybody willing to sell at that price, which, except with a crop like your correspondent "A. G. S." boasts of would hardly pay expenses. The fall in prices comes painfully home to one, when it is recollected that the same firm was offering R37·8 this time last year, with "no takers," and that in the beginning of January we could have got R42·8. There is a general disposition to send the coffee to the London market this year, as two seasons ago, when things looked nearly as bad, planters who sold on the Coast lost heavily in comparison with English prices. However, any of your readers who may be inclined to speculate in this article could buy a good deal at 35, which, from what I can hear, is our "irreducible minimum" f. o. b. just now. An unusual feat was performed by a planter near Maypady a few days ago, who shot two elephants, right and left, in thick jungle; one was killed, and the other badly hit, tried to get up, but was settled by a third bullet. A Ceylon man did the same thing some years ago, but in the open where he had suddenly come upon a herd, two of which charged him. With the numerous abandonments that have recently taken place near the Ghauts, it is probable that elephants will become commoner in Wynaad than they have been. A good deal of timber cutting is going on, especially of blackwood, which always commands a fair price in Calicut. It costs a good deal, though, before it can be got down there, for elephants to drag it out of the jungle, and for cart hire. With a railway, or even a steam tramway through the district, a very large timber trade would soon spring up, especially with Mysore, where wood is very scarce. But as times are hard we cannot wait for the railway, and have to manage with existing agencies. The extension of the Madras line to Calicut is being at last pushed forward. This will be a great convenience to trade on this coast, and will probably lead to the extinction of Beypore, which only exists as the present terminus. I see there is still a good deal of correspondence in the *Mail* about advances to maistries, but I think "Justice" hits the nail on the head when he advises the limiting fresh advances to a certain sum. This plan has been tried with success on some estates in Wynaad. Mr. Teare's suggestion that Superintendents should be made liable for advances is a sufficiently absurd one. I fancy a Superintendent could no more be held responsible by a proprietor for money given out to procure labour, than he could be held responsible for the cost of the manure he has applied to the trees if it did not produce ten hundredweight an acre. A Superintendent is usually given a certain estimate to work to, and is presumed to do the best he can for his employer. No Government would pass a law to punish him for anything but positive fraud; short of that a proprietor must be expected to protect himself; he can easily dismiss his Superintendents if they do not act as he wishes, but he cannot expect them to share in the risks without sharing in the profits of ownership. The only plan for owners, if they wish to avoid further loss, is to do as the much abused "Planter" is going to: let them have the courage of their opinions, and order no more money to be given out to maistries. We gave up hoping against leaf disease years ago, after we had tried all the nostrums of scientists without much effect; we are still trying to combat it with better cultivation, and with shade, which we are happily not now beginning to plant, as your correspondent supposes. He will find, when he takes a walk abroad, that shade has been largely established all over Wynaad, and with excellent results. It is aggravating to find a planter of such standing bragging of the way he illtreated his coffee in "the good old times." No doubt he did get big crops, but so did others who cultivated properly; the difference is visible now, when half the Ghaut estates have gone out under such management as he fondly records, while others that were taken in time are still to the fore. The Panorah Company's estates have changed hands, having been bought by a gentleman in

London, a Mr. Nicholson. The fact of the sale was known here some weeks ago, but for some reason an affectation of mystery was kept up as to purchaser's identity, till it at last it began to be suspected that Mr. Grant Duff, who refers enthusiastically to the situation of the Panorah bungalow in his recent Minute, was going to throw off the cares of State and settle among us. Such is, however, not the case. I understand that the new proprietor does not intend to reside here. The weather has at last taken a turn, and we are having a splendid time for crop. Planters at Sultan's Battery and elsewhere, where coffee ripened early, were picking heavily in the recent downpour, and are delighted at the change. We are not so glad of the arrival of the landwind, though it dries our parchment at a great rate, for the coolies are beginning to get fever, and our paper and cheroots commence to curl up under its influence.—*Madras Mail.*

TEA-PLANTING IN CEYLON is attracting the attention of Indian planters. We hear of one gentleman who, after being nearly 20 years a tea merchant, came out to India to learn planting, and, after qualifying as planter, looks to Ceylon for the investment in a garden. He should start here with many advantages in his favor.

MALACCA.—It is estimated that the combined tapioca planters have sustained here, through the low price of the produce, losses to the large sum of $956,000. It is true that some of the earlier planters made large sums at the commencement of the manufacture of tapioca, but others who commenced later have nothing to show, but a record of losses.—*Singapore Free Press.*

TEA IN CACHAR is thus referred to by the Darjeeling correspondent of the *Indian Planters' Gazette*:—I am sorry to hear that tea has done very badly in Cachar this season. As regards quantity, there is not much to complain of in that district, but the general run of prices have been so low as to entail a serious loss on the working of many concerns, some of which, it is said, must inevitably close, as it will be impossible to find money to carry on with until the opening of the next manufacturing season. Most of your readers will have noticed how few actual transactions in tea shares have been quoted in the share lists during the last six or eight months.

VANILLA CULTIVATION IN COLOMBO.—Although the cultivation of vanilla and the curing of the produce have succeeded fairly well at the Peradeniya Gardens, all attempts to rear this valuable product in Colombo have hitherto, so far as we know, been unsuccessful. A visit to the well cultivated grounds of "Wilhelms Ruhe" has, however, shown us that this delicate plant can be cultivated and made to fruit with complete success within the limits of the town. Mr. W. H. Wright, who has for a number of years devoted his attention to horticulture, has brought a number of vanilla plants into active bearing, and in the fullest vigor of vegetable life. In other garden products, as well as in the bearing of a variety of fruit trees, Mr. Wright has been very successful, and his grounds will amply repay a visit.—Local "Times."

A FISH-KILLING PLANT.—At the recent meeting of the British Association, Professor Moseley made observations on a common water weed, *Utricularia vulgaris*, which trapped young fish. This plant, two to three feet high, grows in ditches and stagnant pools near Oxford. It has a number of small bladders, the size of a pear, hitherto supposed to be for the purpose of containing air to float weed at certain seasons of the year. These bladders were really traps, in which very small fishes were caught and killed. He found this to be correct by experiment, it having never been believed carnivorous plants preyed upon vertebrates. The bladder had an opening secured by an elastic door, which yielded to the pressure of the fish, immediately rebounding with sufficient force to securely fasten the intruder. If the fish are very small they got completely inside, but generally they were caught either by the tail or the head, being held till dead. No bait seemed to attract them. It has not been proved that the weed digested the fish, but the belief was that the hairs on the inner surface sucked the protoplasm formed from decomposing bodies.

THE DISCOVERY OF COFFEE.—Toward the middle of the fifteenth century a poor Arab was travelling through Abyssinia, and finding himself very weak and weary from fatigue, he stopped near a grove. Then, being in want of fuel to cook his rice, he cut down a tree covered with dead berries. The meal being cooked and eaten, the traveller discovered that the half-burned berries were very fragrant. He collected a number of these, and on crushing them with a stone he found their aroma increased to a great extent. While wondering at this he accidentally let fall the substance in a can which contained a small supply of water. Lo, what a miracle! The almost putrid liquid was instantly purified. He brought it to his lips; it was agreeable, and in a few moments after the traveller had so far recovered his strength and energy as to be able to resume his journey. The lucky Arab gathered as many of the berries as he could carry, and having arrived at Arden, in Arabia, he informed the Mufti of his discovery. The worthy divine was an inveterate opium smoker, who had been suffering for years from the influence of the poisonous drug. He tried an infusion of the berries, and was so delighted with the recovery of his own vigour, that in gratitude to the tree he called it *cahuah*, which in Arabic means *force*. And this is the way coffee was discovered.—*Public Opinion.*

BECHE-DE-MER.—The fishing for the sea slugs known as *bêche-de-mer*, on the coast of the Fijian Islands, and on those of the northern coast of Australia, is a profitable occupation, for the Chinese pay well for these marine luxuries. It is not, however, without its drawbacks, as is evident by an account which appears in the *Cairns Post* of an adventure which befell two fishermen at Green Island. It seems that it is the custom to take a certain number of the natives to assist in diving, and in the management of the boats, and these assistants are not always trustworthy. In the case in question the two men had left their long boat at anchor, and had gone in the dingy with the natives to the reef, a mile distant, on whose edge *bêche-de-mer* was found. While the men were at work the treacherous natives slipped into the boat and rowed away, leaving their employers to be drowned by the rising tide. One of the men was a good swimmer, but the other was ignorant of the art. The former started to swim for the long boat, which he reached, but was utterly exhausted before he arrived there. He managed, however, with great difficulty to get up the anchor, and then made for the reef, which he reached only just in time, the tide having risen above his comrade's arm-pits before the boat arrived to his rescue. The natives made good their escape to land twelve miles distant in the boat they had stolen. It is plain that the fishery of the *bêche-de-mer* is not without its drawbacks.—*Ibid.*

PANWILLA, MARIA, 10th Dec.—I have no doubt there are many planters like myself who did not know of this new variety "Cundeamar cacao," the flesh of which always remains green, who will thank Doctor Trimen for the information given in his last letter. If a new plant or a new variety of an old plant is fruiting and seeds are for sale, would it not be well to let the same be made known through the papers or even through the *Gazette* by the Director of the Peradeniya Gardens giving full particulars and so give all a chance. I have no wish and do not act the critic, but do wish that all planters would prosper in Ceylon, and I devote much time and care to study the wants (nourishment) required for and a prevention to attacks of insects on our coffee and all other products, whether successful or not. I have asked planters to visit and satisfy themselves—nothing like one's seeing for themselves and I know of no one who paid me a visit who was not satisfied that estates can be made in spite of leaf-disease, dry weather and bug still to give paying crops. My variegated cacao tree continues to fruit well, though the present crop is all of one sort—not three kinds as last year—each pod contains from 40 to 44 seeds, the rind is thin, the seed weighs about 2 to 2¼ oz from each pod after curing. I gathered 20,000 pods last week; not one pod was touched by squirrels or helopeltis. Cacao in our district is a great success.—J. H.

THE AMERICAN EVAPORATORS.—We are glad to learn from Messrs. W. H. Davies & Co. that they are erecting a No. 3 evaporator at Messrs. Carey, Strachan & Co.'s Mills in Colombo, where they purpose testing it with cacao and cardamoms and any other available product. The machine will be ready by Wednesday next. Mr. R. S. Fraser will shortly have a machine (No 2) on his estate; one left yesterday for Blackstone to be tried with tea, and another is going, on orders, to Cyprus estate. We hope, soon, therefore, to be informed of the adaptability of the machine for tea drying.

WHEAT AND WOOL IN SOUTH AUSTRALIA are thus noticed in the *S. A. Register*:—Harvest prospects continue brilliant, and unless tempestuous weather prevails during the reaping operations a general average of 10 bushels to the acre may be fairly calculated upon. It is now generally acknowledged that last season's yield exceeded the official figures by about one bushel per acre, bringing up the average to something like nine bushels to the acre. The quantity of wool passing through Port Adelaide this season is unprecedentedly large. From August last no less than £56,000 bales have passed over the railway, and four firms alone show an increase of 15,000 to 16,000 bales on the number received by this time last year.

TEA INVESTMENTS.—Certain calculations have been made, writes a London correspondent of the *Indigo and Tea Planters' Gazette*, by which it has been shown that the money vested in all the tea properties in India having their head-quarters in England; (*i.e.* in those Companies known technically as "English Tea Companies") returned 6½ per cent. last year, if worked out over the whole of the money so invested. Such a return from produce in these days is certainly encouraging, and if it be only maintained along-side of the heavy losses sustained in so many of the produce markets, English investors will not have much cause to complain of their speculation in Indian tea property, bad times notwithstanding.

SUGAR.—From Eastern Java it is reported, that twelve more sugar factories will shortly stop working, not being able to keep up with the present price of the article. The Banks, fully aware that they have already gone in too deeply with advances, are not willing to assist any any further, and it is feared that some of them will suffer such great losses by the present sugar-crisis, that it becomes doubtful whether they will be able to stand it. In the meantime, many people will be without work, and without means to support themselves. What will be the end of this? In Europe, also, the low prices of sugar have already created great miser in Austria, and able judges give as their opinion that Germany will, shortly suffer no less, unless some great but unexpected change should take place, by the several Governments putting their heads together.—*Singapore Free Press*, Nov. 22nd.

DARJEELING.—It has been proved conclusively up here, on the small scale of course, that leaf mould, and virgin soil and thoroughly well rotted cattle manure applied freely to the roots of the tea bushes will undoubtedly have the effect of mitigating the attacks of red spider, and it has also been proved that putting *tictia put* (the wormwood so common in the hills) round the bushes and letting it rot there will certainly give the green fly notice to quit. Mud applied to the leaves of the bushes has certainly the effect of stopping the spider; but the process appears to be too slow and too expensive for universal adoption on a large scale. It does appear from this that the soil where bushes are attacked must be deficient in some important chemical constituent, and it is here that the advice of an agricultural chemist would be simply invaluable. Red spider, whether rightly or wrongly, is supposed to have been introduced into the hills through the medium of seed from Assam, and there is no mistake whatever about the spider spreading speedily from bush to bush and from garden to garden.—*Planters' Gazette*

TEA IN CHINA.—We alluded in last weekly summary to Mr. R. S. Fraser's importation of silkworm eggs. We may add that Mr. Fraser's impression of the tea he saw in China and Japan was, that it was very badly pruned, the branches being much guarled. The leaf in Japan was somewhat larger than that of the bushes in China, but nowhere could the tea compare with good Assam hybrid.

CITRIC ACID is much in favour in France as an antiseptic. Specimens of meat placed in only a five per cent solution of it for 15 days are said to have been taken out perfectly preserved. Even a weak solution is stated to cause death to bacteria. Could it not be advantageously employed as a dentifrice, for a German dentist has recently shown that *caries* is due to certain fungi?—*Australasian.*

DARJILING TEA—Nov. 23rd.—The tea season of 1884 may also be said to be closed, and I doubt if the result will be altogether satisfactory to shareholders. Brokers say that the tea manufactured was not all round up to the average of previous years, and prices have been low. However it may be, there will be no dividends on any but the best and oldest gardens, and even these will not be much to boast of.—*Englishman.*

TEA MACHINERY IN CEYLON.—Further improvements in tea-preparing machinery form still the order of the day: the latest exhibited is a "Tea sifter and separater" invented by Mr. Gore, which, as may be seen from the report given elsewhere, is regarded as doing very satisfactory work. It is further stated, that Mr. David Fairweather of Sembawatte has invented what he terms "a green-leaf spreader" whereby much time is saved in spreading and taking off the leaf from the withering tats. It is described by a contemporary as follows:—The leaf is spread on an endless tat 6 feet long, spread on rollers. From this it drops on to the withering tats, which are also endless, and may be erected about 60 feet in length, supported by light wires across them. When one tat has carried its leaf to the end, the "spreading" tat is raised at one end about 7 inches, and the same operation gone through until all the tats are filled. The spreading only never moves from the spot, and by this machine one man will spread from 400 to 500 lb. of green leaf per hour. In taking off the leaf the tats are made to travel round the rollers, and the withered leaf falls off at the end, thus saving a great amount of time. We congratulate Mr. Fairweather on his simple but effective invention, and are glad to learn that his method of spreading leaf is to take practical effect in the extension of the Sembawatte and the New Mariawatte factories.

CEYLON COCOA.—I have recently been instituting enquiries as to the present extremely low price of Ceylon cocoa as compared with the rates ruling during last year, which you will remember topped all, or nearly all, other quotations. I remember about that time that you stated in your local issue that a famous foreign manufacturer of fancy chocolate had been so much struck with the fine flavor and richness of your cocoa that he he had instructed his Colombo agents to secure all they could obtain of like quality at the same figure as the first lot was bought. I am not certain as to that amount, but I rather think it was R48 or R50. Now I think the Colombo rate is down to R32, and here the article commands about the same figure as the ordinary Trinidad. As I cannot ascertain the opinions of the continental manufactures, I am obliged to be content with that of the Mincing Lane brokers, and they assure me that the English makers of flake and ordinary cocoas complain of your article that it is much dry and not containing nearly so much of the natural fatty matter of the bean as some of the West India sorts, and it does not absorb the same quantity of arrowroot or sago-flour which it is desirable to "blend" with it, as do other kinds, hence it is rather out of favor. That is probably true enough, but it is a curious fact that it was precisely this small proportion of fatty matter which commended the Ceylon bean from Pallikelle and Ambecotta to the continental makers of fine fancy chocolate. What are those buyers doing that they are now indifferent to your parcels of fine cocoa, or can it be that they continue to buy quietly in your market all the fine suitable parcels?—London *Cor.*, Local "Times."

COFFEE IN BRAZIL.—This empire claims to possess 800,000,000 coffee trees, covering over 2,000,000 acres of land, about 400 trees being planted to each acre. Each tree averages about one pound of marketable coffee per annum. The coffee industry of the empire gives employment to 800,000 persons, mostly slaves.—*Planters' Gazette.*

PRECAUTIONS AGAINST TEA ADULTERATION.—No teas imported in Queensland will be allowed to go into consumption which contain less than 30 per cent. of extract three per cent. of soluble ash, calculated on the dry tea, 212° Fahrenheit, or more than eight per cent of total ash.—T. M. King, Collector of Customs, Brisbane, 25th August 1884.—*Indian Tea Gazette.*

THE VALUE OF LIBERIAN COFFEE.—It will be seen that a small parcel of Johore Liberian coffee was sold this week by public sale at 44s to 46s, having been pronounced by brokers an unusually fine sample. Only a few days before, a small lot of Liberian, dried in the cherry, was sold at 43s per cwt. being required, it is understood, as seed, and this latter came from South India. The price is equivalent to fully 70s per cwt. for clean coffee.—*Planters' Gazette*, Nov. 1st.

FERTILISERS.—A prevalent, but much mistaken, opinion and belief is that salt, lime, and plaster are not fertilisers or manures, but that they exercise some such effect upon plants as stimulants do upon animals, and are, therefore, of questionable value at all times, and sometimes and under some circumstances are positively injurious. This opinion, of course, is only held by persons who do not understand what manures and fertilisers really are, or what plant food is, or how plants are constituted. Manure, in its general sense, is anything that is added to the soil to supply plant food to it. Plant food is any substance that plants require for their growth and take from the soil for the purpose of building up their tissues. Now, all plants contain chlorine and soda in varying proportions and lime in large quantity. Salt consists of sodium and chlorine, and if the soil is not supplied naturally with these elements in sufficient quantity, salt is indispensable to the growth of crops quite as much as common manure is.—*Queenslander.*

TEA.—Our Jorhat correspondent writes:—The last week we have been experieneeing very warm weather, and the sun has been pouring down his rays with a truly oriental fervour. It has not been favourable for leaf as there has been no rain at all, and the ground is becoming as hard and dry as if it was the month of Jaunary rather than September. Gardens that are behind now will have little chance of picking up anything to speak of, as the tea season promises to close very early this year. This scorching sun is also detrimental to new clearances, where the young seedlings, if kept too free from jungle and unshaded get burnt up by the heat. The orange bug or beetle has also been very destructive to young plants this season, cutting the tip off and sucking the juice which stunts the plant though not killing it. Altogether it has not been a favourable year for extensions. Since writing the above we have had some capital showers which will benefit the bushes greatly, though for those who are behind, it is perhaps rather too late to hope to wipe of arrear now.—*Indigo and Tea Planter's Gazette.* [Has this orange bug been seen in Ceylon.—ED.]

SILK-WORM MANAGEMENT IN CHINA.—In China, the hatching of the eggs of the silk-worm takes place about the 20th of April, and according to Chinese account the rearing should be accomplished, if the weather is warm, say 69° to 74°, in 23 to 24 days. A Chinese work on sericulture is quoted from as follows by a Shanghai exchange :—" If the meals of mulberry leaves be given frequently the worms will advance rapidly to maturity ; and if seldom, they will be long in arriving at the mature age. If this stage be arrived at in 25 days it is calculated that each hurdle of worms will produce 25 ounces of silk ; if in 28 days then each hurdle will produce only 20 ounces ; but if the worms are a month or 40 days in coming to maturity, then each hurdle will only give ten or a dozen ounces ; when the silk worms fall into and awake from their torpor at irregular intervals the silk will be deficient in quality. After the great (fourth) torpor, silk worms only require 15 or 16 meals before they arrive at maturity." And these must be very large ones, as may be judged from the following remark : " When the worms are aroused from their third torpor, put a pound of them in one basket from which you will afterward obtain eight pounds' weight of cocoons."—*Japan Mail.*

TOBACCO AT THE STRAITS.—Judging by the climate, the rainfall and the nature of the soil and forest, it appeared as though all products grown in Ceylon would thrive there. The timber appeared to be of a specially fine character and of large size and well adapted for building purposes. As regards tropical products, Mr. Elphinstone is much impressed with the prospects of tobacco cultivation, for which he considers the soil, and in some of the drier districts, the climate of Perak admirably suited, as he does the eastern end of the Badulla district, where a fine sample of tobacco used to be grown in former years, but we are not aware whether it is still produced there. A relative of one of the Penang merchants had not long ago retired with a fortune of £70,000, realized in a little more than five years, made in Sumatra, where the climate is very similar to ours in Badulla. This cultivation is worked by Chinese lahor, and it is scarcely necessary to say that it is a cultivation in every way suited to them, requiring much care and patience. A tobacco plantation is worked by giving out the ground in one acre plots, which the Chinaman works, and is paid according to the quantity of leaf he brings in, the drying and curing houses, of simple construction, being arranged along one side of the estate.—Local " Times."

PINE-APPLE CULTIVATION.—A correspondent in the North writes to us to ask how the European market may be best supplied with Queensland pine-apples; and which of the fifty-two cultivated varieties are best suited to the circumstances of this colony. Queensland pine-apples shipped from here in a cold chamber have arrived in London in a condition almost equal to that of fresh gathered fruit. Whether they would do so in every case is not certain, though the probability is that they would. But they are regularly shipped home in a preserved state, the entire process of preservation being very economical and simple. The pines are merely peeled, then put into a tin just large enough to hold them and a little water, and a lid with a small hole in it is soldered on. The fruit in the tin is boiled sufficiently to kill fermentation germs and to drive out all the air as much as possible, and then the hole in the lid is closed with a drop of solder, thus rendering the tin air-tight. The tins require testing before shipment to make sure they are air-tight, and this is done by putting them into a copper, when if any air-bubbles arise the soldering must be perfected or the contents of the tin will go bad. The best variety of pine to grow for profit is what is known as the Queen pine; it is very prolific, delicious in flavour, and exceedingly hardy. The appliances necessary for turning the leaf into fibre would be costly, and could hardly be worked satisfactorily in connection with growing and preserving the fruit, but the latter could be made to pay handsomely.—*Queenslander.*

" DESCRIPTIONS OF EXOTIC FRUITS NEW TO QUEENSLAND,' BY L. A. BERNAYS, Esq., F.L.S., &c.—The plants now bearing, for the first time in Queensland. The fruits referred to were—1st, *A Dillenia* (*D. speciosa*, Thumb. or *D. Indica*, Linn.), an inhabitant of India and the Malay Archipelago. This the author described as an evergreen of ornamental appearance, attaining a height of over 40 ft., and of considerable commercial value for its timber alone. The fruit, specimens of which were exhibited, consists of two parts—1st, a fleshy calyx; 2nd, the fruit proper, composed of several cells growing together around a fleshy centre, each cell containing numerous seeds surrounded by a gelatinous pulp. It was said to be employed by natives of India for use in their curries, for jellies and for an acid fever drink. The tree affording material for the paper had proved to be a prolific bearer in the gardens of the Queensland Acclimatisation Society, and Mr. Bernays recommended the plant as especially adapted for the rich coast lands of the colony. 2nd. A *Harpephyllum* (*H. Caffrum* Bernh., or *Spondias Caffra*, Weisner), a native of Caffraria, attaining a height of 30 ft., and presenting a rather striking appearance from its terminal bunches of leaves. The fruit consists of a drupe about an inch long, bright crimson when ripe, with a large bony "stone." Though of no value for the table, its pleasant sub-acid flavour would render it a desirable addition to garden produce. The tree from which the specimens of fruit exhibited were derived could be seen growing in the plantations opposite the houses of Parliament. The curious fruits of the dillenia exhibited, though unripe, created some interest.—*Queenslander.*

CINCHONA AND COFFEE IN SOUTHERN INDIA.

TO THE EDITOR OF THE MADRAS MAIL.

SIR,—My idea that cinchona is suitable to grow with coffee, as shade, your Wynaad correspondent regards as an astounding assertion. Your correspondent should travel and gather wider experience, rather than treat and settle matters from his own contracted sphere of observation. Coffee will go back under the shade of the best known trees, such as fig, unless the shade is treated, as experience shews necessary, by lopping up gradually every year until the lowest branches are 12 feet above the coffee or more, to admit light and ventilation. Where coffee has been stifled by cinchona left in a state of nature, with its branches among the branches of the coffee trees, the coffee languishes. Leaving opinions, however, for discussion, and moving to facts, I will quote one instance, of several known to me. On an estate in the Bambn district of Coorg, a plot of ground of about a quarter of an acre, was planted up 20 years ago, with, may be, 100 Succirubra trees in the coffee. The cinchona trees were kept lopped up high, the coffee thriving and bearing well under them. Three years ago, or about, the cinchona trees were coppiced, and yielded 1,300 lb. of bark, which sold at 3s. 4d. a lb. The stools of these trees measure 18 to 36 inches in circumference. If not too wise in his own conceit, your correspondent might try the treatment on an acre, and he may discover that his coffee will thrive, and the growth of his cinchona be stimulated by reducing his cinchona trees to one stem, and pruning off the lower branches with a saw every year until they are high above the coffee utilising the bark from the prunings. By this process he will find his cinchona trees more rapidly thicken and the quantity of bark be increased. Many planters, whose opinions command respect, think the quality of the bark deteriorates; that is a debateable point that extensive growers may record their opinions upon; the above quoted instance, and another within my knowledge, do not prove it. These remarks apply to the robust kinds that grow into trees: the shrubby kinds are unsuitable to plant among coffee shrubs. Let us hope your correspondent will favor us with some of his own original ideas, dropping the role of preceptor, and leaving criticisms of the opinions of other writers to your own better judgment and taste. Original opinions from practical men, exchanges of ideas resulting from experience, conceived in a tolerant spirit, and expressed in courteous terms, are calculated to be useful and instructive, but conceited wordy critiques, such as the one under notice from your Wynaad correspondent, serve no useful purpose, adding nothing to the general stock of knowledge on subjects of great interest and moment at the present critical juncture to those engaged in planting pursuits.

PLANTER.

QUEENSLAND: MINOR INDUSTRIES AFFECTED BY KANAKA LABOUR.

COFFEE—TEA—CINCHONA—COCONUT—RUBBER.

Some years ago Mr. J. M. Costello conceived the idea that it would be possible to successfully grow the coffee plant in the Mackay district, and accordingly he selected as the place where he would make the attempt a hill distant about 13 miles northward from the township, and there planted several acres with the coffee plant. The plantation, which at present consists of about 20 acres under cultivation, bears the name of Millicent, and supplies almost without exception the whole district with coffee of excellent quality. The coffee grown is of the kind known as coffee Arabica, which has been found to flourish best in this district, the Mocha coffee having been tried, but not having succeeded as well, it being rather too delicate a plant for the climate. The surface of the hill upon which the coffee is grown is exceedingly rough and stony, and would at first sight appear quite unfit for the purposes of cultivation, but between the rocks and rubble are deposits of rich volcanic soil, and some of the bushes growing on the hillside are splendid specimens of their kind. On the eastern slope where the bushes are well shaded from the wind by a clump of scrub, the plants have attained very great size and luxuriance. Unfortunately, however, Mr. Costello is unable to obtain sufficient labour to keep the plantation well weeded. Properly speaking, the rows should be weeded every month, but this under present circumstances is impossible, consequently out of the 20 acres nominally under cultivation, only about eight acres are really crop-bearing. The crop ripens about June, and at the time of my visit, late in July, many of the trees were still unpicked. A full-bearing coffee bush with its dark-green glossy leaves and scarlet fruit is a very pretty sight, and a hill covered with such can at a short distance be transformed by an average imagination into a huge plum-pudding decked with holly. When fully ripe the fruit becomes darker in colour than in the earlier stages, and it is then picked and spread out in the sun to dry. Each fruit when the outer skin is removed contains two beans. These beans are sometimes sold in what is known as the green state, that is before being roasted. Mr. Costello, however, roasts and grinds all his coffee, and prepares it fit for infusion. He states that he finds a ready sale for all he can grow, and could, had he sufficient coloured labour, find a market for all he could produce. At the present time he is in great trouble, and fears that unless circumstances appear brighter in the future, he will after all his trouble and labour have to abandon the industry. His indentured boys will in a few weeks terminate their period of engagement, and unless he can secure others, or labour equal to it, he will be unable to carry on the work of his little plantation. The supply of kanaka labour is becoming so limited, that it is only with the greatest difficulty that the places of time-expired boys who desire to return home can be refilled, and unless coolie or some such labour can be found to meet the demand, which has so enormously increased of late years, there is no doubt many small farmers and men of enterprise, such as in this instance, will find it difficult, if not impossible, to carry on their operations. To use the words of Mr. Costello, "it means ruin." The proprietor has also several curiosities in the way of trees and plants growing on his farm or plantation. He pointed out a few tea plants, which looked very green and healthy, but he states that tea-growing would not be a success. The plant requires great care and a constant supply of water. A splendid young rubber tree was a conspicuous object. It was but 20 months in age, and had reached a height of 14 feet clear of the branches. The stem was perfectly straight, and without a branch till the crown was reached. The rubber tree is principally grown in South America, and the trade in rubber is confined to a comparatively few firms, into whose hands the plantations have fallen. When sufficiently matured the bark of the trunk is cut in a zigzag form by a knife or other instrument, and a glutinous white matter exudes; this is generally caught in clay moulds, and when the rubber solidifies the moulds are broken, and the rubber is then sent to be manufactured in different forms. Pepper plants, yams, mangoes, and other growths are also represented in the plantation. The cinchona or quinine tree is also cultivated there.

One of the most conspicuous objects to a stranger visiting Mackay is a large coconut grove on the side of the Pioneer River, opposite to that on which the town has been established, and immediately facing the Victorian wharf. This grove is the property of Mr. J. G. Barnes, and is a favourite Sunday resort for the Mackay people. It is now about 20 years since Mr. Barnes crossed the river for the first time, and determined to start his grove and plantation, and about a year afterwards he planted his trees, which for many years have borne him good yields. He has about 20 acres of land under cultivation of one sort and another. The coconut palm have been planted in the sandy soil near the river bank. They are laid out in eight rows, each of about 25 palms, at regular intervals one from the other. The first impression on entering the grove is, that the palms are so many immense columns up-bearing the roof of an ancient temple. Under the four spread leaves of the palms are clustered great bunches of nuts in all stages of development. The sheath has just opened, and the nodules on the branch are seen; then on the same palm, there is the nut, quite green, and beside it the yellowy brown husk of the fully-developed fruit.

In all some 20 different varieties of pines in the plantation about four acres being utilised in this way. Elsewhere we saw a quantity of young cocoanut palms being raised. They had been grown from the nut, and appeared to be strong, healthy plants. Talking of cocoanuts, Mr. Barnes stated that, with his best palms, he had, in some seasons, from one alone, taken as many as 400 nuts. He has also about six acres of land planted with bananas, principally of the cavendish variety. The soil does not appear to be altogether favourable to the growth of bananas, but notwithstanding, the yield, I was informed, was in some seasons very large. The plantation was in very good order, and, as with the cocoanuts, the fruit could be seen in every stage of development. First of

all, among the broad green leaves appears the blossom, of a rich purple colour. The blossom opens, and inside is seen the stamens, to which the young fruit are attached. The upper portion of the blossom serves as a cap to protect the fruit from the direct heat of the sun until it is sufficiently matured to ripen unprotected. When the fruit is gathered, the branch of the banana upon which it has grown is cut down and laid at the root, and a new plant springs up. We were also shown some date palms, but they were not bearing at the time. The curious fact—that is, of course, to laymen—of the division of the palms, coconut as well as date, into sexes was explained to us. The pollen of the blossom of the male tree is carried by insects or by the wind to the flower of the female tree, where in due course it fructifies. The paupau tree, or mammy apple, was another curiosity to us. It bears a fruit gathered in a cluster beneath the crown of foliage surrounding the tree. This fruit somewhat resembles in appearance the melon; and indeed is, in colour and flavour, not unlike the rock melon. It is stated that if a piece of tough meat is hung on its branches, the meat will become in a short time quite tender.—*Sydney Mail.*

AMOUNT OF OIL IN LINSEED CAKES.

(*To the Editors of the "Tropical Agriculturist."*)

LONDON, NOV. 7th, 1884.

GENTLEMEN,—The enclosed is a printed copy of a short paper I have prepared for the Irish Farmer newspaper, and which has been favourably received here by all parties interested in the purchase of Linseed Cakes, inasmuch that too much importance had been placed upon the amount of oil, whereas the hard-pressed western cakes of America have been found by farmers to give excellent results as a cheap feeding cake. I thought you might like a copy for your paper or the *Tropical Agriculturist.*—Yours very truly,

JOHN HUGHES.

At the present time stock feeders are busy preparing for the winter markets, and the selection of the most profitable feeding materials is a matter demanding careful consideration.

With Wheat so cheap and in such good condition as it is this year, many shrewd, practical men will probably consider it more economical to employ it when crushed as a partial substitute for some kind of Oil Cake, and thus make their wheat crops literally walk to market.

Be this as it may, a certain quantity of good Linseed Cake will no doubt be required as usual, for long experience has firmly established the superiority of this Cake over those made from Rape or Cotton Seed, and its market price influences that of all others. Indeed, the price of Linseed Cake is far more constant than its composition, specimens of very different quality being frequently offered at the same price by rival merchants, and it is to be regretted that samples are not accompanied by a guarantee as to chemical composition, in the same manner as artificial manures are sold. If this were done, farmers would know more about the quality of their feeding cakes, and would be able to trace the cause of their stock doing so much better on one kind of cake than on another.

At present Linseed Cake is usually purchased according to the brand, some manufacturers taking more oil out of it than others, according to the pressure exerted and the character of the seed operated upon. Manufacturers who are careful always to purchase well-matured Linseed, of good quality, free from dirt, and with only a small proportion of foreign weed seeds, naturally acquire for their brand of cake a well-earned reputation and an enhanced price. The amount of oil left in the cake will, of course, vary according to the market price of Linseed Oil, for it must be remembered that the cake is a "residual product," the manufacturer's primary object being to extract the oil, and that he only allows a certain proportion to remain in the cake because it pays him better to do so than to employ greater pressure and extract more completely.

This variation in the quantity of oil left in the cake has led many persons to attach an undue importance to its presence as an exact indicator of the general feeding value of respective samples, and to forget that the nutritive value does not depend solely upon the proportion of fatty ingredients, but also, and to a very considerable extent, upon the large quantity of albuminous (flesh-forming) compounds, mucilage, and digestible fibre which should exist in all good cakes, and further, to the special readiness with which these constituents are likely to be assimilated. Moreover, the proportions of woody fibre (or cellulose) and dirt in the form of sand are most important factors to be considered when determining the probable digestive character of any particular sample of cake. Lastly, the amount of moisture is important, for with a high percentage the cake, if kept in a badly ventilated place, is very likely to get mouldy, whereas a dry, hard-pressed cake can be kept for months under ordinary circumstances in excellent condition. Thus it will be seen that in order to give a reliable opinion upon the quality of a cake, a full analysis, and not simply a determination of the amount of oil, is necessary to be made, and we must consider all the points of importance if a correct judgment is to be arrived at.

Linseed Cake comes, it is true, under the general title of an Oil Cake, in the same way as Cotton or Rape, because it is a cake made from the residue of a seed rich in oil, and not because oil alone is to be considered its principal feature as a feeding material. Of late the manufacturers have thought it economically desirable to introduce improved machinery, and by pressing harder have reduced the percentage of oil from about 12 or 14 to 10, and in some cases as low as 7 per cent in the cake; consequently the proportion of oil has become quite a vexed question, and Dr. Cameron, at a recent meeting of the Royal Agricultural Society of Ireland, read a paper on the nutritive value of Oil Cakes, in which he specially pointed out the marked reduction in the quantity of oil now present in Linseed Cakes. He stated that since 1880 the average amount in samples submitted to him rarely exceeded 10 per cent, and sometimes fell as low as 6 per cent, and it seemed absurd that special brands which still contained 11 to 12½ per cent should be sold at the same price as those containing only 6 to 9 of oil. Dr. Cameron actually proposed that 10 per cent of oil should be considered the minimum amount of that ingredient which should entitle a Linseed Cake to be sold at the current price of that article, and suggested that for every 1 per cent less than 10 there should be a reduction of 5 per cent from the price. For example, if the current price of good Linseed Cakes was £9 10s. per ton, then a cake containing 9 per cent of oil should be sold for £9 0s. 6d and a cake having only 8 per cent for £8 11s. per ton; in other words, a deduction of 9s. 6d. for every 1 per cent of oil under 10.

Now this deduction seems to be far too much and is purely empirical, as we have no practical feeding experiments available upon which to establish reasonable grounds for assuming that the loss in the feeding value of a cake is in proportion to these figures. Dr. Cameron does not say that an equal addition should be made for every 1 per cent of oil above the minimum of 10, and he was wise in refraining from doing so, for at 9s. 6d. per unit a ton of Linseed Oil would cost £47 10s., whereas, the present market price is only about £22, or 4s. 4¾d per unit.

I submit that it is not usual to value the presence of a comparatively small quantity of an ingredient such as oil in a bulky material like cake at a higher rate per unit than it can be purchased in the concentrated form of Commercial Linseed Oil.

If the feeding value of Linseed Cake depended solely upon the proportion of oil contained, surely cakes would long since have been sold at prices regulated by the percentage of oil which they were found on analysis to contain, or we should have used the pure oil itself sprinkled over the cut food.

According to Dr. Cameron, two cakes otherwise equal as regards the amount of albumenoids, mucilage, and digestible fibre, but containing in one case 7 per cent of oil, and in the other 10 per cent, should respectively be sold for £8 1s. 6d. and £9 10s.

Assuming, as I have said, that both cakes are equal in other respects (and this can readily be ascertained by making a careful analsyis), it appears reasonable to conclude that the farmer will find it more profitable to purchase the cake containing 7 per cent of oil at £8 1s 6d., or if he wishes he can expend this sum in buying more cake of the same quality, so that in one case he will have 1 ton 3½ cwt. against 1 ton.

In these calculations it has been taken for granted that the proportion of the flesh forming constituents has been equal in each cake, but as a matter of fact the sample which contains least oil will have a decidedly higher proportion of albumenoids, as well as more mucilage and digestible fibre, while from being hard-pressed there will be less water and the cake will be likely to keep better.

In conclusion it may be mentioned that capital machines are now to be had for readily crushing cakes into a meal day by day as required, so that the objection against hard-pressing goes for nothing, and it is a recognised fact that cakes are more economically used for feeding purposes when given in the form of meal than in hard lumps or broken pieces, which can scarcely be properly digested with a view to future assimilation by the most robust of animals, and which in the case of inferior quality of cake frequently produces serious internal irritation in young or weakly animals.—JOHN HUGHES, F.C.S., *Agricultural Analyst.*

ENEMIES OF TEA.—Our entomological authority reperts as follows on the caterpillars sent to us from Dolosbage:—"They appear to be the larvæ of a moth belonging to the genus Orgyia. They are often found in vast numbers and are very destructive to vegetation."

COCONUT PLANTING.—An energetic countryman of yours, Mr. S. T. Muttiah, has largely invested in land in the Puttalam district which is the best suited for coconut, cultivation. The venture is regarded as a very bold one as Mr. Muttiah has had to pay rather high for the land, as the result of competition from a quarter whence he least expected it, but it is hoped that the richness of the soil will make up for the enhanced price, and that under careful management a valuable property may be formed. Coconut is king all over Ceylon—*Com.*,—"Jaffna Patriot."

RUBBER: WHAT DO CEYLON PLANTERS SAY TO THIS:—The province of Amazonas has passed a law prohibiting the tapping of rubber trees 2½ meters from the ground, the tapping of young trees, or these less than 25 years old, and the injury or destruction of young trees. The fine is fixed at 1,000$ for each infraction. A premium of 1,000$ is offered for each thousand trees planted and cultivated, at two years of age, besides other favours to cultivators. To guard against foreign competition, an export duty of 5$000 is levied on every rubber plant, and 100$ on every kilogramme of rubber seed exported.—*Indiarubber and Guttapercha Journal.* Oct 8th.

GALL INSECTS ON TEA (Referred to by Mr. Karslake).—"Royal Botanic Gardens, Peradeniya, 27th Nov. 1884.—The tumours are without doubt, as you suggest, *galls*. They are produced by the irritation and consequent hypertrophy caused by the fluid injected by the female insect along with the egg or eggs. The gall insects are hymenopterous, and called *Cynipidæ*. In these tea leaves the eggs are evidently laid in the under surface near or in the mid-rib of the leaf. All the specimens sent are quite recently formed, and no *larvæ* have yet appeared. I have not detected the eggs, but that is not surprising, as they are probably extremely minute. The jambu-trees here and elsewhere are very liable to a somewhat similar gall.—(Signed) HENRY TRIMEN."

SOME time since Dr. Müllenhoff arrived at the conclusion that in sealing honey cells bees add formic acid to the honey by thrusting the abdomen with the sting protruding and a minute drop of poison adhering into the half-closed cell. The honey taken from sealed cells is said to be much more stable than that taken from unsealed cells, and Dr. Müllenhoff attributed this to a difference in respect to its contents in formic acid, which is known to be a powerful antiferment. He, therefore, treated 100 grams of unsealed honey with 0·1 gram of formic acid, and preserved it and the same quantity to which no acid had been added under similar conditions; after a time it was found that the first sample remained unaltered, whilst the second was undergoing fermentation. He, therefore, proposes to make a technical application of this observation by adding the formic acid to the unsealed honey, and thus sparing the bees the time and labour involved in sealing the cells. Dr. Müllenhoff states that one part of 25 per cent acid is sufficient for 250 parts of honey.—*Pharmaceutical Journal.*

THE GROWTH OF FLAX.—Climate and soil are, of course, most important factors in the successful cultivation of the flax plant. Mr. Warden says the climate most suitable for the growth of the plant is one having a regular supply of genial moisture in spring, without an excess of wet in autumn, and where the temperature is equable. The delicate leaves are then unable to exclude the scorching rays from the surface of the soil, and as the roots have not had time to penetrate sufficiently deep to secure a supply of moisture, the plant droops, turns a whitish yellow, and, if the drought continue long, it dies. Long-continued droughts are, therefore, a great enemy to the flax-grower, and these are less frequent in the British Islands than on the Continent.—*Public Opinion.*

WHY CONTAGIOUS DISEASES ATTACK BUT ONCE.—Professor Tyndall thus endeavours to explain the immunity obtained against a second attack of a contagious disease:—"One of the most extraordinary and unaccountable experiences in medicine was the immunity secured by a single attack of a communicable disease against future attacks of the same malady. Small-pox, typhoid, or scarlatina, for example, was found as a general rule to occur only once in a lifetime of the individual, the successful passage through the disorder apparently rendering the body invulnerable. Reasoning from analogy, I have ventured to express the opinion that the rarity of second attacks of communicable disease was due to the removal from the system, by the first parasitic crop, of some ingredient necessary to the growth and propagation of the parasite."—*Phrenological Journal.*

A DECOCTION OF LEMON is reported by Dr. Aitken, of Rome (*Brit. Med. Journ.*, Oct. 4, p. 653) to be a very valuable remedy in the treatment of ague. A dose is prepared by cutting a freshly gathered and unpeeled lemon into thin slices, adding three teacupfuls of water, boiling until reduced to one teacupful, and allowing the decoction to stand all night in the open air, when after being separated by filtering and pressing from the rind, pulp and seeds, it is ready for administration, and should be given at once, first thing in the morning. Dr. Aitken says it has never seemed necessary to give more than one such dose daily. Although the method of preparation is somewhat crude, this may be condoned in consideration of the results reported to have been obtained. Dr. Aitken's speculations have failed to identify the active principle to which the antipyretic action is due, though he is sanguine that it will soon be extracted and come into general use; but he remarks that "the alkaloidal principles, hesperidine and limonine, said to be obtained from lemons, are quite unknown to medicine," and, it may be added, to chemistry too.—*Pharmaceutical Journal.*

THE PREPARATION OF CHINA TEA.—A correspondent at one of the Chinese tea ports furnishes the following particulars of the way in which the trade is conducted, and no one knowing anything of the very different way in which Indian and Ceylon teas are prepared for the market will wonder that they command better prices than the China:—In former years teas were carried to Canton for sale, and brought fine prices. Of late years, however, there is generally a loss of 20 per cent on cost of production, but how they can manage to carry on a trade under such circumstances I cannot understand. The preparation of the tea is a costly and tedious affair. The tea trade commences now in May. People are bringing in their teas in small parcels of three or four pounds to the receivers or Hongs. Some of these Hongs have a hundred men or more employed to select and pack the teas. These men have to be well paid, as the work must be done smartly and well, so as to catch the market and preserve its quality. In the first place the tea has all been sorted by hand, and both ends of each leaf nipped off, leaving just the body of the leaf only to pass as first quality tea. The work is done by women, whose nimble fingers manage to do a lot in one day, and at lower wages than men would do the work for. The careful selection and equal nipping is thus an important matter, but the proper firing is undoubtedly the most important of all. Careful packing is also an indispensable necessity in order to preserve the aroma of the tea on the voyage, as no amount of proper firing can preserve the quality unless it is also well packed.—*Planters' Gazette.* [The above paragraph must be from the pen of a careless observer, for we suppose the statement that both ends of a tea leaf are nipped off is absolutely incorrect.—ED.]

INTERNATIONAL FORESTRY EXHIBITION AT EDINBURGH.

The importance of the study of Forestry to the nation at large, and indirectly to pharmaceutical chemists, is best illustrated by a reference to the results obtained in India, Jamaica, and Ceylon, where the cultivation of the cinchona has become a prominent industry. It is largely owing to the strenuous endeavours made by the pioneers of the Forestry Department in India that the valuable febrifuge alkaloids of cinchona bark are now brought within the reach of even the very poor in India.

But many other remedies used in medicine besides cinchona are forest products, and the visitor to the International Forestry Exhibition now being held in Edinburgh need not be surprised to find that drugs form a prominent feature in several colonial departments. It is proposed, therefore, to give in these columns some account of the principal drugs exhibited and of such products as seem capable of being more extensively used if better known.

Taking the exhibits in the order in which they will be seen by visitors to the building, the first to be noticed are Stands Nos. 31 and 32, where the forest products of—

THE GAMBIA AND SIERRA LEONE

are shown. These are naturally somewhat similar in character, and as those from the Gambia are accompanied by a very voluminous report, from Capt. C. A. Moloney, C.M.G., the Governor of that colony, relating to the products of Sierra Leone as well, the products of the two provinces can be most conveniently treated of together. Much information concerning these exhibits has been derived from the abovementioned report.

The chief articles of export from Gambia which can be classed as drugs are palm kernels, palm oil, indiarubber, and camwood. From Sierra Leone, in addition to the above, there are exported ground nuts (*Arachis hypogæa*), copal, Benne seed (*Sesamum indicum*), ginger and red pepper, and in lesser quantity Calabar beans, melon seed, arrowroot, and Shea butter. Of these Shea butter can scarcely be called a native product, being produced much more abundantly on the banks of the Niger, and melon seed, which is used as food in Gambia under the Mandingo name of "sarroh," appears to be imported from Abbeokuta. The latter is, however, also exported from Sierra Leone, to a limited extent (£139 in 1882). The seeds yield about 30 per cent of a pale limpid oil, which dries slowly. It has been shipped to France, but seems unknown in this country as a commercial product.

The specimens of palm from Gambia include the ordinary yellow kind and white and black palm kernel oil. The yellow oil is obtained from the fleshy pulp of the drupaceous fruit, and the kernel oil from the seed. The manner in which these oils are obtained is described in Capt. Moloney's Report, and may be summarized as follows:—

The Yellow Oil.—The bunches of fruit are allowed to dry for a week or ten days in the air, until the fruits can easily be detached by beating, when the scales at the base of the fruits are removed by rubbing them in the hands in a windy place, by a rough kind of winnowing. The nuts are then buried in a hole in the earth about four feet deep and lined with plantain leaves, in which they are allowed to remain until the pulp is as soft as if boiled, which is in from three to twelve weeks. The fruits are then removed to a similar hole in the ground lined with flat stones and beaten with wooden pestles till the flesh is removed from the fruit stones. Portions of the mass are now boiled in water, the fruit stones being removed, until the oil runs out. The marc is then pressed in cylindrical nets twisted by means of sticks inserted at the ends.

The process of fermentation in the ground injures the quality of the oil, and the shorter that process the sweeter and more liquid the oil.

For home consumption the natives make a better preparation by boiling the fruits in iron pots instead of fermenting them, then working the pulp into a paste with tepid water, passing it through a sieve and boiling it with water until a bright red oil floats on the surface. It is then strained and heated to drive off any water it may contain.

Palm Kernel Oil.—The white oil is prepared from the kernels. To obtain these the stones or endocarps are allowed to dry until the kernels become so tough that they are not crushed when the shells are broken between two stones. The kernels, after removal from the shells, are pounded in a mortar, then ground more finely between grinding stones, and the resulting mass put into cold water and stirred with the hand until a straw-coloured oil rises to the surface in lumps; this, on exposure to light and air, becomes perfectly white.

The black oil is obtained by heating the kernels in a frying pan, when the oil runs out and is collected and strained. It has an empyreumatic odour, and is not easily decolorized; hence it is of little value.

Specimens of the wooden mortars and pestles used for the purpose of pounding the seed are also exhibited. In size and shape they resemble a large iron mortar. They are made from a hard wood known as "gree-gree."

The palm trees are said to commence bearing when from seven to twelve years old, and to yield during thirty-five or forty years. A single tree affords 20 pounds of the fruit during each season, when in full bearing, the size and fruitfulness of the tree being dependent, however, upon the nature of the soil. The harvest is chiefly collected during the rainy season. Several varieties of the oil palm are known on the Gold Coast, under the names of royal, white, red and black palm, differing chiefly in the character of the fruit.

Some idea of the importance of this industry to the West African Colonies may be gathered from the fact that the exports in 1882, from Sierra Leone alone, were, palm, nuts £101,165, palm oil £47,217, besides larger quantities from the Gold Coast, the total imports of nuts and oil into the United Kingdom being estimated during the same year at £484,309.

Specimens of the oil of the ground nut (*Arachis hypogæa*) of native manufacture are placed side by side with others imported from this country and France and compare favourably with the latter, both as to colour and brilliancy. The amount of nuts (botanically legumes) exported from Sierra Leone in 1882 was valued at £15,217.

The Benne seed (*Sesamum indicum*) exhibited is the white variety. This seed, which yields Gingelly oil, appears to be exported almost exclusively to France, and although some comes back to the colony in the form of oil, it does not appear to what purpose the larger proportion of oil is applied. The value of these seeds exported from Sierra Leone in 1882 was £10,002.

A white fatty oil is also exhibited together with the fruit *Hyphæne crinita?* known in the Jolof language as "sippe," and in the Mandingo as "kalo." This solid fat is stated to be used for cooking purposes, and the pulp of the fruit is eaten by the natives. The kernel of the fruit is hard and horny, like that of the vegetable ivory nut (*Phytelephas macrocarpa*) and gives no evidence, in the state in which it is exhibited, of containing any oil.

The Tooloucoonah or Coondee seeds (*Carapa guineensis*) and the oil obtained from them are also shown. This oil is worthy of note as a product which might be developed into an important industry, as the seeds could be obtained in unlimited quantity. In French Guiana, where the tree also grows, the trees are said in some places in the forest to cover the soil a foot deep. The oil makes excellent soap, and is said to be valuable as a lubricant, protecting iron and steel from rust in a remarkable degree. It is used in British Guiana under the name of crab oil, and is employed to anoint the person in order to keep off the mosquitoes, for on account of its intense bitterness it repels all insects. A soap made from this oil might possibly serve the same purpose if used in washing. In this country the oil is a soft solid. Although Tooloucoonah oil was awarded a prize in the International Exhibition of 1851, it seems to have been undeservedly neglected. The kernels are valued in the Gambia at about two shillings a bushel.

Some interesting specimens of indiarubber are exhibited, both from the Gambia and Sierra Leone. The latter are accompanied by specimens of the leaves and stems of some of the plants yielding it. In the Gambia indiarubber is comparatively a new industry, the exports having only commenced in 1882, when their value reached only £114. The quality of the first export was so good that in 1883 the amount had increased to £5,107, the greater proportion of which was taken by France. The adulteration practised by the natives in consequence of the increased demand led, however, to a subsequent decline in its value and in

the trade. In Sierra Leone, however, it forms one of the principal articles of export, being estimated in 1882 at £126,806.

In Capt. Moloney's Report some interesting notes on the production of rubber have been collected together, from which it appears that—

"The milk of different rubber trees varies considerably in fluidity and physical properties. In the case of *Landolphia florida* the juice dries so quickly that it forms a ridge on the incision. The natives, therefore, make long cuts and wipe the juice off with their fingers as it exudes, and smear it on their arms and shoulders until a thick coat is formed. This is then pulled off and cut into small squares, which are then said to be boiled in water."

There appear to be two principal kinds of caoutchouc found on the banks of the Gambia—one of these is white and elastic. The tree yielding this is called in the Jolof language "tawl," and in the Mandingo dialect "choley," but on the Gold Coast "panwee." The description of the bark, wood and fruit appear to correspond closely with that of *Landolphia owariensis*. The other is called "maddah" (Jolof) or "cahbah" (Mandingo), and is considered to yield rubber of an inferior quality. The firstnamed is locally valued at 1s. 4d. to 1s. 6d. per lb., and the second at 1s. In the Gambia the rubber is collected as follows:—

"The bark is sheed or incised on one side of the tree, deep enough for the juice to start out in drops, and salt water, diluted with fresh water, is sprinkled from a bottle or calabash, which causes the juice to coagulate rapidly. Inland, where sea-water is not procurable, a solution of one part of salt in three of water is used. Some of the milk is then dabbed on the forearm, and as soon as dry it is peeled off to form a nucleus. This is then applied to the fresh cuts one after another, and being turned with a rotary motion, the rubber is cleanly wound off from the cuts like silk from a cocoon, the semi-coagulated milk being thus drawn out of the bark around the incision. During this process a break is said to be of rare occurrence. The average amount thus obtained is about two and a half pounds per day, although as much as five pounds has been collected. These trees, or rather climbing shrubs, appear to be less injured by the process of tapping than the large trees of South and Central America, for Sir John Kirk states that he has seen hundreds of trees in full life so thickly scarred with cuts that nearly two-thirds of the bark must have been stripped from the tree. They will also endure a considerable drought and flourish in a light sandy soil. The rubber is not always, however, so pure as it should be, and hence merchants on the Gold Coast have recently purchased the milk at 9d. a quart obtained from species which yield it in a more fluid state in order to boil it down and dry it. Rubber so prepared realized last year 2s. 11d. per lb. As much as 12 cwt. of rubber has been prepared in this way in a week with the aid of one assistant."

Copal.—Only a small specimen of this resin is exhibited. It forms, however, one of the more important articles of export from Sierra Leone, the value of the exports of copal in 1882 being estimated at £11,262. It is supposed to be the produce of *Copaifera Guibourtiana*, and is valued at 1s. per lb., or when cleaned at 1s. 10d.

Another resin under the name of Gum Santang is exhibited from the Gambia. It is used medicinally by the natives and as a disinfectant, but is sold only in small quantities in the Mandingo and Jolof countries. The tree is, however, abundant on the banks of the Gambia river, and the resin appears worthy of being experimented upon.

Ginger.—The specimens of ginger exhibited are inferior in appearance, but the article is probably capable of improvement in quality by careful manipulation. The exports to Great Britain and the United States in 1882 amounted to £7,917.

A small collection of drugs from Sierra Leone, sent by Mr. Sibthorpe, includes the following:—Egbessye root, obtained from the African peach, *Sarcocephalus esculentus*, and used throughout the west and south of Africa as a bitter tonic for indigestion, just as gentian is used in this country. Finger root, an aromatic stimulant, probably obtained from *Uvaria chamæ*, and apparently widely used on the west coast of Africa. Cashew gum, *Anacardium occidentale*, which affords an adhesive but somewhat gelatinous mucilage; cashew and mangrove barks used in tanning; and a kind of grass, called sumach grass, used for dyeing straw, etc., yellow.

Cola Nuts.—These are exhibited both in the form of seed and young fruit by the lastnamed and other firms. According to Capt. Moloney this nut is not grown in Gambia, but is mostly imported from Sierra Leone, the value of the exports from the latter country having been £33,108 in 1883. It also forms a regular article of export to Brazil from Lagos and Loanda. In the Portuguese possessions in Africa these nuts are said to be eaten in the morning with a small piece of ginger, but in the Mombuttoo country, according to Schweinfurth, they are chewed in the intervals of smoking. On the Gold Coast the tree is known as bisé, and according to Capt. Moloney's Report several varieties are recognised by the natives. Thus besides the red and white cola nuts there are "*bisé bio*," the spurious kola nut, and "*sua bisé*," the white-nosed monkey's cola nut; the latter is abundant and an oil is extracted from it; these varieties, however, unfortunately are not exhibited. The chewstick of West Africa is made from the roots of the true cola, *C. acuminata*. In the Mandingo language the cola is called "coorooah," and in that of the Jolof country "gooroo."

Several drugs are also exhibited by the Compagnie du Senegal at Sierra Leone, amongst which may be noticed "maluka" seed (*Polygala oleifera*), apparently used as a source of a fixed oil; black seed, which has kindly been identified by Mr. J. R. Jackson, of Kew, as that of *Hyptis spicigera*, but the use of which we have not been able to learn; Calabar beans of good quality; three varieties of castor oil seed of different sizes; Eguse seed; beeswax, and cbillies. Castor oil seeds and the oil expressed from them, liquid honey and beeswax, both crude and purified, are also exhibited from the Gambia.

The export of chillies from Sierra Leone in 1883 was valued at £1,291, and of Calabar beans at £759. The latter were also exported from the Gold Coast in 1881 to the extent of £125. Other articles of interest from the Gambia are native honey, the fruits of *Detarium senegalense* and of *Xylopia æthiopica*, native indigo in the form of balls formed of the crushed plant (*Lonchocarpus cyanens?*), the gum of *Khaya senegalensis* or native mahogany tree, and the seeds of *Cassia occidentalis*. The lastnamed, although roasted and used like coffee in some parts of tropical Africa are used in the Gambia only in their natural state as a purgative medicine.

The fruits of *Xylopia æthiopica* are used by the natives as pepper, and are known as "country spice"; in medicine they are employed as a stimulant for the mucous membrane. In France, preparation of this fruit have been used for some years as a substitute for cubebs in gonorrhœa, leucorrhœa, etc., and have the advantage over that drug of a more agreeable taste. The fruits of *Detarium senegalense* are eaten by the natives, but it appears that two varieties exist, one of which is very bitter and is believed by the negroes to be poisonous. As with bitter almonds, however, there is no means of distinguishing the two except by taste.

Kino.—In the Sierra Leone exhibit, a specimen of the old original kioo, obtained from *Pterocarpus erinaceus*, is shown. This is said not to gelatinize when made into tincture like the kino obtained from *P. Marsupium*. It is of a brighter colour, having the tint and transparency of garnets. It appears to be known to the Portuguese as *Sangue del Draco*, but is not a regular article of commerce. There can be but little doubt, however, that if it were restored to the Pharmacepœia it would soon come again into commerce.

INDIA.

The Indian Department occupies the whole of the right hand portion of the central transept, and the collection of drugs from the different provinces forms a prominent feature of the exhibit. Although a notice of the other forest products would be somewhat out of place here, attention may be directed to the numerous uses made of the timber of the padonk tree, *Pteracarpus Indicus*, which yields also a liquid kino. The teak tree is worthly of note as having been the means of drawing the attention of the Home Government to the importance of conserving the forest trees of India, and of having thus led to the establishment of the Forestry Department in India. Colonel Michael has adopted a simple but ingenious method of showing the structure and grain of the timber exhibited. A section of the trunk is sawn half way through

longitudinally, and then half through horizontally, and a portion obliquely, showing in one piece what is only observable from three pieces in other exhibits. A very interesting account of the history of the establishment of this department is given by Sir George Birdwood in the first catalogue of the Exhibition. From his report the last sentence may be quoted, since at least this department of the Exhibition should not be alluded to without giving the credit that is due to the two gentlemen therein mentioned.

"It is a happy omen that the first International Exhibition of Forestry should have been appointed to be held in the stately capital of Scotland, where scientific forestry throughout the British empire received its earliest impulse, and that the Exhibition should be so much indebted for its prosperous issue to the co-operation of Colonel Michael, the pioneer of practical forestry, and of Dr. Cleghorn, the father of scientific forestry, in India."

The largest collection of Indian drugs is that described as the "Index Collection," sent by the Government of India, and includes, besides other forest products, gums and resin; dyes, tans and mordants; oil seeds and medicinal products, all arranged in groups. Other collections worthy of notice are those sent by the District Officer of Malabar (2); by the Assistant Conservator of Forests in Kanara, Bombay (32), the specimens being in good condition and accompanied with useful information on the lables; by the District Forest Officer, Coimbatore, Madras (35); by the Conservator of Forests, North Division, Bombay (27); and by the District Forest Officer, Tinnevelly (36), the two lastnamed being evidently carefully selected and labelled. Allowance, however, must evidently be made for some of the other collectors, with whom there has evidently been a great difficulty in obtaining bottles and printed labels.

The drugs in these collections from the different provinces are of course many of them identical, and have most of them been described by Dr. W. Dymock in his valuable 'Materia Medica of Western India,' as well as in papers in this Journal on the same subject. A few of the articles, however, may be noticed here.

Khasya Turpentine.—This is prepared in Assam from *Pinus Khasyana* in a very crude fashion, which may be summarized as follows:—

A hole is cut 9 to 12 inches wide, 6 to 9 inches high and 2 to 3 inches deep in the trunk of the tree about a foot above the ground. A strip of the bark and a little of the wood 12 inches wide and 4 feet up the tree is then removed. When the turpentine has well exuded and become solid, which takes place in about twelve months, it is removed, and the wood, cut up in small pieces, 2 to 5 inches long and $\frac{1}{4}$ to $\frac{1}{2}$ inch thick, is placed in earthen pots, which are covered with perforated leaves and then inverted over holes made in a hearth cut out of the hill side. This is so arranged that when hot ashes or burning charcoal are placed around the inverted pots the turpentine runs through holes in the hearth and is received in pots placed at its outer edge; $6\frac{1}{4}$ lb. of wood are found to yield 1 lb. of turpentine, but this is not the whole that could be obtained, as there is some waste in the process. The wood used for the purpose sells locally at the rate of 80 lb. for a rupee.

Among other drugs noticed were, *Blumea lacera*, an Indian plant recently described in this Journal by Dr. Dymock; *Amomum subulatum*, the source of Nepal cardamom, indentified during the last few years; plantain seeds, to which attention has recently been directed by Mr. W. T. Thiselton Dyer; and the aloe wood of Scripture, *Aquilaria Agallocha*. In the Malabar (2) collection a sample of the bark of *Syzygium jambolanum*, recently recommended for the treatment of diabetes, may be seen. Several specimens of jequirity seed (*Abrus precatorius*) of different colours are exhibited from different provinces, those in a very excellent collection of drugs from Cuddapah being of a pure white colour, while a second sample of a buff, and a third of purplish-black hue, are contributed by the district officer of Arcot. Specimens of these have been kindly presented to the museum of the Society by Colonel Michael, and together with a dark brown specimen from British Guiana were lent for exhibition at the meeting of the British Medical Association at Belfast, where the subject of *Abrus precatorius* was discussed. Some fine specimens of native vegetable fixed oils are exhibited by Mr. J. H. Brougham, of the Anantapur district, and some essential oils by Professor Lawson, the recently appointed Director of Gardens and Cinchona plantations on the Neilgherry Hills. Those sent include the oils of *Gaultheria fragrantissima*, *Eucalyptus Globulus*, *E. piperita* and *Andropogon citratus*, DC., or lemon grass. Fine specimens of the bael fruit, cassia fistula pods, nux vomica seeds, including the valuable variety grown near Bombay, and many other familiar drugs too numerous to mention, may be seen well represented in this department.

Before leaving the Indian court the visitor should not neglect to see a very complete set of the vegetable dyes of India shown in silk, etc., by Mr. T. Wardle, of Leek, Staffordshire.

BURMAH.

The Conservator of Forests, Pegu Circle, exhibits, among other articles, three varieties of cutch (*Acacia Catechu*) wood oil, and an indiarubber obtained from *Chavannesia esculenta*, which appears to be of excellent quality. A number of tanning materials are also shown here in sufficient quantity to permit of chemical examination, which it may be hoped will be undertaken by chemists interested in these products. From Oudh there is exhibited a new tanning product in flat cakes like those of *Areca Catechu*, known as sal extract, and said to be obtained from the bark of *Shorea robusta*; and from Assam, some fine specimens of the rubber of that country.

ANDAMAN AND NICOBAR ISLANDS (16).

The objects of pharmaceutical interest here are few in number, although the magnificent specimens of polished timber vie in beauty and size with any in the Exhibition. Some fine specimens of wood oil or gurjun balsam are here exhibited which present the appearance of an emulsion, and appear to have been obtained from the tree without heat. By the Burmese this oleoresin is used in leprosy and for gonorrhœa, and also in the arts, for mixing paint and as a varnish, and for rendering torches inflammable. Some fine pieces of a resin named ingdwe, derived from *Dipterocarpus Hasseltii*, are also shown here. When dissolved in benzol this resin makes a rapidly drying varnish for photographic plates. It is of pale colour, and appears to be hard. It is used by the Burmese for stiffening varnishes, and for caulking and other purposes.

CAPE OF GOOD HOPE (33).

This is only a small exhibit; specimens of dried aloes juice, bush tea (*Celopia latifolia*), and the tanning barks of *Acacia decurrens*, *Podocarpus latifolius* and *Leucospermum conocarpum*, are almost the only drugs exhibited. The wood of *Oreodaphne bullata* is remarkable for its disagreeable odour, whence its name of "stink wood." Specimens of the wood from which the natives make their assegais are also shown.

CYPRUS (34).

This is a small exhibit. Specimens of the resin of the *Cedrus Libani* and of *Pinus Laricio* are here exhibited, and sumach leaves (*Rhus Coriaria*), used in tanning.

MAURITIUS (35).

This exhibit consists principally of a fine collection of fibres. There are, however, good specimens of indiarubber, representing the different plants from which it is collected in the island, viz., *Vahea madagascariensis*, *Ficus elastica*, *Cryptostegia grandiflora* and *Manihot Glaziovii*. The last named is cultivated in the island.

CEYLON (38).

Although small in comparison with the Indian collections, the Ceylon exhibit is a well-arranged and an exceedingly interesting one. The exhibitor, Mr. J. Alexander, has an estate in Ceylon, and has evidently taken great pains to illustrate all the productions of that island.

The first object to attract attention from a pharmaceutical point of view is a series of cinchona barks, accompanied with drawings of the plants, together with neat specimens of flowering twigs mounted on cards. These are beautifully prepared, the leaves and flowers having retained their original colours better than any specimens the writer has seen. The species illustrated are *C. succirubra*, *C. robusta*, *C. officinalis*, vars. *Condaminea* and *crispa*, *C. Calisaya*, vars. *vera* and *Javanica*, *C. pubescens*, *C. Ledgeriana* and *C. micrantha*. Both

natural and renewed barks are shown, and in some instances root bark and shavings as well. A box of the tools used in collecting and harvesting the bark illustrates the process of renewing the bark, which is rendered more easy to understand by an album of photographs which represents the collection of cinchona, as well as that of cinnamon and of other products. The tools consist of an American box shaver, a east iron concave and a convex shaver, and a small and large peeler for stripping off the bark. An ordinary pruning saw and a large pruning knife are also used in the process, but as they are not special tools they are not shown.

Before the visitor has remained a few seconds in front of this exhibit he becomes sensible of a delicious fragrance, the source of which is not at first apparent; it proceeds, however, from a window-screen close by which is made of the roots of kus kus (*Andropogon muricatus*), used in Ceylon and India, when sprinkled with water, to cool and perfume the air, but in this country the root is better known under the name of "vittie vayr" or "vetivert," and chiefly used as a preventive of moths. Beside the collection of cinchona barks there is a number of other barks used in medicine by the natives, whose names and uses for these barks are not devoid of interest. As but little is known on these points, Mr. Alexander kindly allowed the use of his notes for the purpose of recording such information here. To these a few additional notes have been added, which have been enclosed in brackets.

1. *Acacia concinna* "Hingooroo-wel."—The decoction of the bark is used for ulcerated throat. [In other sections of the Indian Department these fruits are shown as a tanning material.]

2. *Acacia stipulata*, "Mara."—Used for swellings.

3. *Artocarpus integrifolia*, "Oos."—The inner bark of the root of the Jack tree, which is of a rich orange colour, is used in dyeing the robes of the priests.

4. *Alstonia scholaris*, "Rookatana."—In Ceylon this bark is used in the treatment of cutaneous and scrofulous diseases. [In the Philippines it is used in fever and in India in dysentery.]

5. *Bombax malabarica*, "Kata imbil."—An astringent gum is obtained from the bark.

6. *Briedelia retusa* "Kata-kela."—The sap from the bark is used in the treatment of sores.

7. *Barringtonia racemosa*.—The decoction of the bark is considered to be a good tonic.

8. *Careya arborea*, "Cahatta."—Used in medicine as an astringent. It is considered to be one of the best tanning barks in Ceylon. [The bark being fibrous is also made into a rough cordage, and in some parts of India is said to be prepared for use as a slow match. According to Dymock, it contains much mucilage and is used for preparing emollient embrocations.]

9. *Celtis dysanocyton*, "Gooranda."—A piece of this bark hung up near a dwelling-house is used as a charm to drive away evil spirits. This bark when broken has a disgusting odour, like that of human fæces, which is also possessed by the wood [and is probably due to the presence of naphthylamine].

10. *Cinnamon*.

11. *Calosanthes indica*, "Jobilla."—Said to be used as a dye. [In India, however, it is held to possess powerful diaphoretic and slight anodyne properties. Dr. Evers treated twenty-eight cases of acute rheumatism with the bark, and in all the results were most satisfactory. He considers that when combined with opium it is a much more powerful sudorific than the compound ipecacaunha powder. The dose of the powdered bark is 5 to 15 grains in infusion (Dymock, 'Mat. Med. of W. India,' p. 457.]

12. *Cassia Fistula*, "Ahalla."—A decoction of the bark is used as a purgative.

13. *Casearia zeylanica*, "Walwaraka."—The bark is used as an anthelminthic.

14. *Cyminosma pedunculata*, "Anu kenda."—The extract of the bark is used as an application to bruises and sores.

15. *Crateva Roxburgii*, "Lurnwarana."—Said to yield a medicinal oil.

16. *Eugenia revoluta*, "Welle damba."—Used for bruises.

17. *Eugenia assimilis*, "Kosdamba."—The juice from the bark is considered to be cooling and is used for rubbing over the skin.

18. *Ficus laccifera*, "Nugu."—The lac insect lives on the bark

19. *Glycicarpus racemosus*, "Balla."—The juice of the bark causes great pain and swelling.

20. *Garcinia Morella*, "Gamboge."—The bark is used as a yellow dye.

21. *Gmelina Rheedii*, "At-de-Mettia."—The decoction is given to women after childbirth.

22. *Phyllanthus emblica*, "Metti."—The bark is used in tanning, as well as the fruit and is considered one of the best for the purpose. [In the Indian exhibit from Cuddapah some very perfect fruits of this plant may be seen.]

23. *Leea Staphylea*, "Booreola."—The young stems are used as a remedy for fever.

24. *Macaranga tomentosa*, "Kenda."—Used for cuts and bruises.

25. *Nauclea cordifolia*, "Collong."—A cooling plaster is made from an extract of the bark.

26. *Nauclea sp.*, "Bakome."—The decoction is used for venereal diseases.

27. *Paramingyna monophylla*, "Wallangeriga."—Used as a dye. [In Goa, according to Dymock, it is used as an alterative tonic.]

28. *Pongamia glabra*, "Madul Carrandu."—The inner bark is used in medicine [probably for cutaneous diseases.]

29. *Sapindus laurifolius*, "Penella."—The decoction is employed as a tonic.

30. *Symplocos coronata*, "Allu bombe."—Used in ophthalmia. [*S. racemosa* is employed for the same purpose in India.]

31. *Schleichera trijuga*, "Cong."—Used in tanning.

32. *Tabernæmontana dichotoma*, "Diwi Kaduru."—Used as an application to bruises.

33. *Thespesia populnea*, "Gau surria."—Used for bowel complaints.

34. *Terminalia Chebula*, "Arallo."—Used for tanning.

35. *Tinospora cordifolia*, "Rassa sinda."—The young stems are used in fevers.

36. *Vitex altissima*, "Melilla."—Possesses purgative properties.

The specimens of native oils exhibited include those of *Azadirachta indica*, *Bassia longifolia* or mee oil, *Canarium zeylancium*, or kekune oil, *Calophyllum Walkeri* or kina oil, and those of *Corypha umbraculifera*, *Dipterocarpus glandulosus*, "Dorana," and *D. zeylanicus* or hora, and others which are better known.

Coconut oil is represented under three varieties,—the ordinary, an extra fine quality used for hair oil, and the oil of the king coconut, which is a large variety of the fruit. Arraek, vinegar, treacle, and numerous other products illustrate the value of the coconut palm to the natives, and a similar series of one hundred and seventy articles shows the importance of the Palmyra palm, *Borassus flabelliformis*, in native industries. Tapioca and arrowroot are two of the products obtained from this palm, and splints form another. The arrowroot, which appears to be of fine quality, is obtained from the root.

Besides the barks, of which a list has been given above, there are a series of roots and herbs used in medicine neatly arranged and numbered in separate compartments in a show case. Many of these are familiar as well-known English or Indian drugs. Others less known are—

Guilandina Bonduc (3), "Kooboora."—The root is used in diarrhœa.

Flemingia strobilifera, (4), "Han Pilla."—Use not mentioned.

Justicia Adhatoda, "Paa Wetta."—Used in fevers. [In India it is employed as an expectorant and antispasmodic.]

Jasminum flexile.—The leaves and twigs are used for toothache.

Other remedies which do not seem to be used in India, but concerning the properties of which there is no information available at present, are:—*Lagenandra laurifolia*, *Cynoctonum pauciflorum*, *Xylopia parviflora*, or "Nattu," *Gymnema rotundatum*, or "Kerri angoona," *Clematis Gouriana*, *Alternanthera sessilis*, or "Mokoo-wana," *Phaseolus radiatus*, or "Wal-maa," *Piliostigma racemosa*, or "Myla," *Nymphæa stellata*, and *Elettaria involucrata*, or "Arrata." The last-named root bears a close similarity in colour and general appearance to galangal root, and, were it not for the difference in flavour, might easily pass for that drug.

Other commercial products worth notice are a ver

fine specimen of graphite, dug from the pits in the low-country, sappanwood, the oils of lemon grass and citronelle, and cardamoms. The lastnamed is an article of considerable cultivation in the island, being reckoned by the planters as the fifth in importance, the others being coffee, tea, cinchona and cocoa.

The orchella weed exhibited appears to be the *Roccella Montagnei*.

JOHORE.

Some interesting specimens are exhibited by the Maharajah of Johore. The whole process of the manufacture of gambier, or *Terra japonica*, is illustrated by photographs, and various samples of the drug in different forms are shown. Of these there are four qualities, one of which, in the shape of parallelopipeds, is used instead of areca nut for chewing with lime the betel pepper leaf. Some very fine specimens of guttapercha are here exhibited, as well as gutta taban, a similar but inferior article. Fine specimens of a resin called damar dagang and three qualities of the celebrated Baros camphor, the finest of these being in remarkably large crystals; this product is often sold at Siogapore at as high a price as 10,000 guilders per picul of 133⅓ lb., and eagerly purchased by the Chinese. A number of medicinal roots are also exhibited, but information concerning these was not obtainable.

The soft elastic bark of *Pinus longifolia* is here shown as a substitute for cork.

JAPAN.

This is decidedly one of the most interesting as it is one of the largest exhibits in the building. The specimens are arranged in the most practical and businesslike manner, that enables the visitor to learn much concerning the condition of the science and forestry and the forest products of that singular country. The specimens of timbers are arranged so as to exhibit a dried specimen of the foliage and flowers, and a transverse and longitudinal section of the trunk and the bark, and each specimen is accompanied by a sheet of paper giving all useful details as to the value of the timber and the products obtained from the tree. The collection of drugs is a comparatively small one, thirty-six in all, and although unnamed, the deficiency is amply made up by the courtesy of the Commissioners (one of whom, Mr. Okhuho, the brother of a late student in the Society's laboratory, speaks English), who seem to have information concerning every exhibit at their fingers' ends.

Most of the drugs have been described already in the pages of this Journal. Of those not yet noticed may be mentioned the roots of bō-fu, *Siler trilobum*, Benth. and Hook.; wogon, *Scutellaria lanceolata*, Miq.; kudzu-no-ne, *Panax repens;* sai-ko, *Bupleurum falcatum*, L., and nodake, *Angelica decursiva*, Miq. Three specimens of starch are shown, one obtained from the roots of a leguminous plant, *Pueraria Thunbergiana*, Benth., another from those of *Erythronium grandiflorum*, Pursh., and a third from the rhizomes of the common bracken, *Pteris aquilina*, the latter starch being of a yellowish tint. The beautiful insect wax produced by *Aphis sinensis* on the branches of two Japanese shrubs, *Ligustrum lucidum* and *L. Ibotu*, and hence known as Ibotu wax, forms a noticeable object; it resembles spermaceti in appearance, but is much harder.

The Japanese cedar, a most useful timber tree, well known in this country under the name of *Cryptomeria japonica*, appears to yield in Japan a turpentine of semi-solid resin, which is shown here in small quantity. According to Siebold this resin, which is called by the Japanese sugi-no-jani, is very aromatic and is used to make an incense, much valued by the Buddhist priests. It is employed also in the preparation of a plaster for wounds and ulcers. The resin of *Pinus Thunbergii*, Parl, called "kuro-matsu," is applied to similar uses, and in powder is applied to recent wounds to stop bleeding. Internally it is given as a resolvent and pectoral, and is held as a specific in diseases of the lungs.

The Japanese camphor is exhibited in the crude state. Bird-lime is shown prepared from the bark of *Trochodendron aralioides*, Sieb. et Zucc., and *Ilex integra*, Thumb.; this is used by the Japanese for catching cockroaches, rats, mice and other vermin, for which purpose it is spread upon pieces of cardboard, etc.

Some boxes containing cigarettes present a tempting appearance, but the label indicates that they are made, not from *Nicotiana Tabacum*, but from the leaves of *Sterculia platanifolia*. The foliage of *Styrax obassia*, Sieb., is used for the same purpose.

The tanning materials exhibited are comparatively few and comprise the following:—Japanese galls, containing from 60-63 per cent of tannin, the catkins of *Alnus firma*, 25-27 per cent, the barks of *Myrica rubra*, 11-14 per cent, and of *Quercus dentata*, 2-7 per cent. Besides these, pomegranate bark and an astrigent liquid called "kaki-no-shiba," prepared from the fruits of the Persimmon, *Diospyros Kaki*, is used for giving strength and durability to paper.* In this connection the wood of *Kadsura japonica* may be mentioned, which contains a quantity of mucilage and is also used in paper making.

As dyeing materials there are exhibited a yellow laminated bark, which has been variously referred to *Pterocarpus flavus* and *Euodia glauca*, but is here stated to be the inner bark of *Phellodendron amurense; Imperatora tinctoria*, a grass yielding a yellow dye, and gardenia fruits, which give a saffron colour.

A perusal of the descriptive sheets attached to each exhibit of sections of trees, reveals some interesting information. Thus we learn that maple sugar, a specimen of which is exhibited, is obtained from *Acer argutum* and *A. japonicum;* that oils are obtained from the fruits of *Excæcaria japonica*, *Elæocoeca cordata*, *Camellia japonica* and *C. Sasanqua;* and waxes from the seeds of *Cinnamomum pedunculatum* and *C. Camphora*, and from the fruits of *Litsœa glauca*, *Sapium sebiferum* and *Rhus vernicifera*, the strong wood of *Zelkowa Kaki* being used for making oil presses.

The leaves of *Andromeda japonica* and the bark of *Picrasma ailanthoides*, of which fine specimens are exhibited, are employed as vermifuges; the wooden toothcombs and haircombs which are exhibited, are manufactured from the wood of *Olea Aquifolium*, *Hovenia dulcis*, *Pyrus Ussuriensis* and *Buxus japonica*, the lastnamed being hard enough to be used in making seals, buttons and abacus counters. Some of the woods used by the Japanese for engraving purposes seem worthy of trial in this country. Of these may be mentioned *Magnolia hypoleuca*, which is employed also for lead pencils, *Prunus pseudo-cerasus*, *Distylium racemosum* and *Ilex crenata*. The hard wood of the Japanese pepper plant *Xanthoxylum piperitum*, is used for making pestles. Toothbrushes are made in various forms out of a soft fibrous wood, one end being generally frayed out and the other sharpened off so as to answer as a toothpick. Some, however, are frayed out at both ends, the one end more so than the other; this is intended for washing out the mouth. They are probably cheap enough to be used once and then thrown away. *Viburnum Opulus*, a shrub which is also common in this country, and *Populus tremula*, also an English tree, afford the woods used for this purpose, as well as *Lindera triloba*, a Japanese tree.

A very ingenious chopstick made from the wood of *Nandina domestica* is almost as good as a puzzle. It consists of a piece of wood about the size of an ordinary lead pencil, but with square edges instead of being cylindrical. It is evidently split only four-fifths of the distance, and when the two pieces are pulled apart, so as to form two chopsticks, a toothpick falls out of a hollow in one of them which extends partly below the end of the split portion into the solid wood. Like the apple in the dumpling, the puzzle is to know how it got there. This is done when the wood is wet, the toothpick being then inserted in a cavity made for it by a tool used for the purpose.

The Japanese lacquer tree is illustrated by a fine series of specimens. A coloured drawing of the flowers and leaves is shown, painted on the wood of the tree itself, and framed with longitudinal sections of the branches. Thus the whole of the plant, wood, bark, leaves and flowers are represented within the space of a single foot square. A series of the products of chemical analysis of the natural varnish, including a good specimen of urushic acid, with the lacquer, the berries and the wax obtained from them, and the natural varnish in the dried state are also shown. These are accompanied by an important essay. The ingenuity of the Japanese is very evident in several other exhibits; thus the hollowed out trunks of trees are made to serve as drain pipes; the strong but thin fibrous paper is used, when required, as string by merely rolling it between the finger and thumb into a thread, and it is then amply strong enough for the purpose.

* See *ante*, December 25, 1880, p. 510-511.

BRITISH GUIANA.

A very large number of forest products from this country are exhibited in the central transept, opposite to the Indian collection, but many of them have only the native names, and the catalogue affords no particulars concerning the uses of many of the barks, seeds, etc. The specimens of anime, guttapercha and balata are very fine, and the tonquin beans are of large size. Several seeds, judging from appearance only, seemed worthy of examination, one of these closely resembles St. Ignatius' beans in shape and horny consistence, but is much smaller in size. Another is a species of *Andira* which is likely to possess medicinal properties. The seeds of *Abrus precatorius* here exhibited are of a brown colour, the usual black spot at the end being only of a somewhat darker brown colour. Among other products employed in medicine are wallaba bark, *Eperua falcata*, used for toothache, *Nectandra Rodiæi*, crab oil, the product of *Carapa guineensis*, etc. The curious fruits of *Hura crepitans*, whose seeds yield an oil, are prevented from spliting by the simple expedient of pouring a little melted lead into the centre of the fruit so as to fasten the carpels on the axis. It is much to be regretted that so little is known as yet of the products of a colony so rich in natural objects.

ST. VINCENT (143).

Although small, this exhibit is rather rich in pharmaceutical articles, cowhage pods, castor oil seeds, arnatto, arrowroot, nutmegs, cloves, and *Cassia fistula* are familiar objects. The root of bastard ipecacuanha (*Asclepias curassavica*), the seeds of the manchineel tree, and the oil seeds of *Jatropha Curcas*, and *Aleurites triloba* are not so well known. Here also are exhibited jequerity seeds of the ordinary brilliant red and black colour, and the somewhat similar but larger seeds of *Ormosia dasycarpa;* from the lastnamed seed an alkaloid has recently been obtained by Merck, and has received the name of ormosine. The fruits of the towel gourd, *Luffa ægyptiaca*, are shown in the form of ornamental basket work instead of as flesh gloves. A very beautiful specimen of elemi, catalogued as gum opal, is here shown, but its botanical source is not apparent. Bread fruit starch is another little known product in this country which might be mentioned as worthy of notice. Tadehouna bark, the botanical name of which is not given, is said to be used by the Caribs and others in the form of infusion for dysentery.

The seeds of the Frangipanni trees, *Plumieria rubra* and *alba*, are also shown.

In the Tobago exhibit nutmegs are shown in the form of a pickle, which is stated to be far superior to that of walnuts, and certainly they present a more tempting appearance. This concludes the list of colonial exhibits so far as their interest to pharmacy.

An interesting series of barks of species of Acacia, including those of *A. dealbata* and *A. melanoxylon*, cultivated in the South of France, are exhibited by Messrs. Vilmorin, as tanning barks. The experiments made by this celebrated firm show that these trees will yield a more profitable return than oak for tanning purposes in the countries where they will grow, inasmuch as their quicker growth enables them to produce more bark in a given time, and although it is not so rich in tannin, the larger amount of it gives a larger yield of tannin in consequence.

Of what may be termed that trade exhibits, and which chiefly occupy the centre of the building, one or two demand a brief notice.

Messrs. A. B. Fleming & Co. exhibit a trunk of *Pinus australis*, from Wilmington, North Carolina, showing the mode of obtaining the turpentine by removing the bark and letting the resin trickle down into a cavity near the base of the trunk; also fine specimens of rosin oil, which is now largely used in the preparation of lithographic ink.

Some fine specimens of resins and varnishes are also exhibited by Mr. R. Tait, pharmaceutical and manufacturing chemist, Edinburgh, and Messrs. Craig & Rose. Only one exhibit of pharmaceutical preparations, by Messrs. Lorrimer & Co., of London, is to be seen, and this is limited to preparations of cinchona barks and the alkaloids and scaled preparations made from them.

On the whole, the Exhibition may be regarded as a decided success, and doubtless will result in greater attention being drawn to the importance of forestry and forest products to this country and its dependencies, while the interchange of information concerning the methods adopted in different countries cannot fail to be of advantage to the students of the subject in this country.—*Pharmaceutical Journal.*

GAMBOGE.

TO THE EDITOR OF THE MADRAS MAIL.

SIR,—In reply to your correspondent "Jungle Wallah,' in your issue of the 22nd instant, allow me to state that the cheapest mode of collecting the resin known as "gamboge" is by wounding the trees, and allowing the resin to run out, and concrete over the wound. In Ceylon pieces of the bark are cut completely off about the size of the hand, or say from two to four inches in width, at early morn, and the resin oozes out from the pores of the wood in a semi-liquid state, which soon thickens on exposure to the air, and is scraped off the next morning by the collectors without injury to the trees; and the wound thus made soon heals up, so that the tree is fit to be operated on again. Three kinds of gamboge are to be had in the market:—

1. Pipe gamboge, which is considered the best and is procurable in rolls of about 1½ inch in diameter, and about a foot in legth, with a hole in the centre, half an inch in diameter. This, I believe, comes from Siam.

2. Lump gamboge, which is in masses looking like a hardened yellow paste.

3. Gamboge in tears, that is forming small nodules or lumps. The Gamboge from Mysore, Wynaad and Coorg, is the exudation of the *Garcinia pictoria*. Gamboge is chifly used as a pigment in painting and to colour varnishes; in medicine as a drastic purgative.—JOHN SHORTT.

TEA PLANTING IN THE WESTERN DOOARS.

Under this heading the *Indigo Tea Planters' Gazette* gives a deplorable account of the effects of the feverish climate on young European lads, and concludes as follows:—

What is wanted by the public at home is to know that the pioneers always suffer, that they are badly paid, that they cannot always secure the bare necessaries of life, that the climate of the Western Dooars is not quite what it has been made out to be on newly-opened gardens, and that rapid fortunes are not to be made by tea planters now-a-days; that during the first two or three years a youngster has to rough it in a style a "casual" pauper or a life convict would object to. The remedy for all this is obvious, and would not affect the dividends to the extent of 8 per cent, and would save double that percentage in doctor's bills. The remedy is simply not to send boys out to the Dooars under any circumstances, to pay the assistants well enough to enable them to live comfortably in a climate which is confessedly most trying to Europeans, and to provide good pucca houses for the European staff. Soldiers are not supposed to be sent out to India until they are 20 years old at least, because experience has proved that the youngsters whose systems are not thoroughly formed break down sooner than men of three or four and twenty. But then soldiers are worth about £200 each to the country. No European ought to be sent to a newly-opened out garden in the Dooars under three and twenty, nor unless he has previously undergone a most searching medical examination. [We need scarcely remind our readers of the superiority of the climate of Ceylon, as compared with Assam, the Dooars or the Terrai.—ED]

QUALITY IN TEA.

For a number of years past there has been an apparent desire on the part of China and Japan to ship large quantities of tea with an utter disregard to quality. The mixture that have been served up by these two countries and forwarded over here has tea were sufficiently obnoxious to ruin almost any trade. It has been useless to point out to them the damaging effect this course must ultimately have upon their own position as shippers and growers of tea, for they have kept on manufacturing and shipping the same detestable rubbish. It has been argued that the Japanese and the Chinese are not to be blamed so much as the retailer, because if the retail trade would refuse to buy the spurious mixture, the Japanese would soon discontinue its manufacture. But this argument is only true to a very limited extent and is contrary to the experience of every member of the retail trade, for no matter how desirous they might be to sell

pure tea, there is not sufficient of it upon the market to supply the wants and the requirements of the trade.

It is argued by some that the reason that the Chinese and Japanese adulterate their tea is that it pays to do it. We doubt this very much, for in the long run this adulteration of tea must eventually tell against the growers and shippers. If proof is wanted that this is already the case, it can be found in the gradual decrease in the shipments of tea from both of these countries and a comparative increase of shipments of tea from India, Ceylon and Java. While the exports from China and Japan have declined, particularly from the former country, the average price has also been materially lowered, the increasing popularity of India teas and the pure teas shipped from the two countries in question, ought to be convincing proof that if they were to raise the standard of quality, the tea trade of China and Japan would not be in its present depressed condition.

The Indian, Ceylon and Java tea producers have resolutely refused to manipulate the tea, even though such a refusal at the commencement of their operations was the source of considerable loss; but through the honest, active and energetic policy of making pure tea it has at length had the desired effect, for the consumption of these teas is increasing, and the prices realized for them are above those of their Chinese and Japanese competitors. As an indication of the ultimate triumph of pure teas, we may call attention to the curious fact that Ceylon teas have been shipped to Yokohama, and, further, that they are being sold at retail in that they are being sold at retail in that city. This instance of taking coals to Newcastle is a very forcible illustration of what the Chinese and Japanese may expect if they do not alter their present damaging practices.—*American Grocer.*

SUGAR PLANTING IN OUR COLONIES.

The controversies which have appeared in the *Times* on "The Labour Question in the Pacific" and "The Condition of the West Indies" should be read together, and if the various arguments which have been advanced are well weighed, they should serve to place the planting interest, not only in the West Indies, but in Mauritius, Australia, and Natal, on a far better footing than it has been for years past. Planters are now beginning to know—if, indeed, they are not already aware—with what they will have to contend in the future. The beet-sugar industry still thrives, and will continue to thrive while continental Governments are willing to place a bounty, not only on the export but on the manufacture; and it has been pretty well demonstrated of late that no Liberal or Conservative administration would dare to put on a duty to countervail that bounty. But because English statesmen are not prepared to alter the Free Trade policy to which this country is pledged, is that any reason why the planters in our outlying tropical possessions should be brought to ruin? The answer given by all those who know the enterprising character of our colonists and the vast resources of our Colonial Empire is—decidedly not. The West Indies undoubtedly feel the present depression in the sugar trade more than any other of our tropical colonies. But this is because the planters, hitherto enjoying every luxury, never anticipated such a decline, and have up to the present hardly been able to adapt themselves to the altered circumstances. But we are glad to say that many are beginning to see a silver lining to the dark cloud which has for some time past been hovering over them. Instead of sitting with their arms folded, they have determined to take every means to uphold the reputation of cane sugar in the London market. That it can be so upheld is evidenced by the fact that Demerara crystals still obtain the highest price here, and that a tiny consignment of 14 packets of Australian sugar from Sydney realised in the London market, on August 22, 18s. per cwt. This, we believe, is the first consignment of sugar received from New South Wales. Queensland has occasionally sent a few bags to Mincing Lane, but we believe the highest price hitherto obtainable for Australian sugar in London has been 11s. per cwt. We often hear people say that the times for making money out of sugar in the colonies are over. There never was a greater fallacy. The consumption of sugar is now treble what it was a few years ago, and it is bound to go on increasing. In Mauritius, in Australia, and in Natal, increased attention has of late years been paid to the cultivation of sugar, with the result that all three have been largely benefited. In Queensland, in fact, sugar has risen to be the third industry of the colony, and is the only one which has induced to any extent a permanent settlement on the land. Over 20,000 tons were produced last year, the average gross value of which was taken at £25 per ton, including freight, insurance, storage, commission, and charges, while the average net value to the planter—including all classes of sugars, and the average cost of production, taking good and bad seasons into account, and good, bad and indifferent plantations—was £15 per ton. The yield in Natal for 1882 was 8,007 tons, valued at £200,000. In both countries the returns, it is believed, would have been still greater if more coloured labour had been available. Especially is this the case in regard to Queensland, and it is hoped that the letters which have been published on the coloured labour question will lead to the establishment in that colony of an effective and well-controlled system of coolie labour from India. In 1882—the last return to hand—454,753 acres were taken up on the northern coast for tropical agriculture. These lands are fit for no other purpose, and planters are anxiously awating to develop them by means of coloured labour and the introduction of the most modern machinery. Looking at the sugar interest in our colonies as a whole, it is evident that the planters do not intend to hand over the sugar trade voluntarily to the beet manufacturers, but mean to do all in their power to fight them in the different markets of the world. And they are right. There is plenty of money, if not large fortunes, to be made out of the sugar industry yet, and in the failure of one of the largest Austrian beetroot firms, and the improvement which has set in in the London market, we believe we see the dawn of a new era of prosperity for our sugar-producing colonies.—*European Mail.*

CINCHONA IN MAURITIUS.

Royal Society of Arts and Sciences, 20th Nov.

Dr. Chauvin read an interesting paper on the quinine made from the cinchona trees at "Cluny." Mr. Horne, remarking the dampness of the locality had advised Mr. McPherson to plant cinchona plants. They at first grew splendidly, but having been afterwards abandoned they became choked up with wild raspberries and weeds, and the greater part of those planted on the mountain perished. The rest would have followed, but Mr. Auffray, an employé of the estate, called Dr. Chauvin's attention to them, and and on the advice of the latter gentleman, the proprietor had them cleaned and taken care of. They are now in fine condition. These plants are subject to a disease caused by an insect, but unless they are very far gone the diseased part may be removed and the insect taken out. The cavity is then covered with moss, and has to be kept damp for some days. These experiments prove that cinchona trees can be cultivated with advantage in Mauritius. Those of Cluny produced 18 grammes of Sulphate of Quinine and 4 grammes of Cinchonidine per kilogram of bark. This quinine is chemically pure, and Dr. Chauvin intends making experiments with it, of which he will give an account at a future meeting.

Acclimatisation Society, 21st Nov.

Mr. Potier congratulated Mr. Vankeirsbilk on his success with *gynocardiaodorata* (chaulmoogra). This is a success which procures not only pleasure but profit, for each tree brings in from 200 to 240 francs annually. The president drew the attention of the members to an article in one of the local papers on the banana in Mauritius. He was of opinion that new species should be imported from Madagascar and India. Mr. Lemière laid on the table a paper on *Cassia fistula.*

SLOW-GROWN *vs.* FAST GROWN TIMBER.—A general impression exists, that slow-grown timber is the strongest; but the opinion does not, it is said, stand the test of experiment. There is in London a government establishment for testing the quality and strength of all woods and metals used for government purposes, the chronicles of which are said to be very interesting. Among other things which have been proved there is the fact that fast-grown timber, oak at least, is the strongest, and bears the greatest degree of tension.—*Popular Science News.*

REAFFORESTATION.—In Fiji the necessity of reafforestation has become so evident that the Government has recently issued a regulation that every native above sixteen is to plant trees—two fruit trees and two of useful timber. Defaulters are to be fined 4s., or fourteen days' imprisonment. Very much the same sort of system prevailed in Japan until recently, each family being compelled to plant so many trees, according to its position. For instance, the families of the upper class had to rear 100 trees, while the lower class were let off with forty.—*British Trade Journal.*

PROTECTING STEEL AND IRON FROM RUST.—Professor Calvert has recently made the interesting discovery by practical tests, that the carbonates of potash and soda possess the same property of protecting iron and steel from rust as do those alkalies in a caustic state. Thus it is found that, if an iron blade be immersed in a solution of either of the above carbonates, it exercises so protective an action that that portion of the iron which is exposed to the influence of the damp atmospheric air does not oxidise, even after so extended a period as two years. Similar results, it appears, have also been obtained with sea water, on adding to the same the carbonates of potash and soda in suitable proportion.—*Public Opinion.*

HOW TO MAKE COWS GIVE MILK.—If you desire to get a large yield of rich milk, give your cows every day water slightly warmed and slightly salted, in which bran has been stirred at the rate of one quart to two gallons of water. You will find, if you have not tried this daily practice, that your cow will give twenty-five per cent more milk immediately under the effects of it, and she will become attached to the diet as to refuse to drink clear water unless very thirsty. But this mess she will drink almost any time and ask for more. The amount of this drink necessary is an ordinary water pail at a time, morning, noon and night. Try it farmers, and you will be glad.—*European Mail.*

CORAL FISHING.—Coral fishing is largely followed in Algeria, 40,000 to 45,000 pounds of coral, valued at about £38,000, being the yearly production. La Calle is the centre of this industry, and there are employed annually 160 boats and 1,300 men. The coral is obtained by means of a wooden apparatus in the shape of a cross, having in its centre a leaden slug or stone for ballast. Nets, the meshes of which are loose, are hung on the bars of the cross and dragged at the bottom of the sea, and among the nooks and crevices of the rocks. These nets, winding about the coraline plant, break up or tear off its branches, which adhere to the meshes. The apparatus is drawn up by the fisherman whenever he thinks it sufficiently laden. There is also a net which is provided with large iron nails, having thus great force to break the coral, but this apparatus is forbidden to be used.—*Public Opinion.*

THE culture of the tea trade in Transcaucasia, which has been recently advocated by Dr. Woeikoff, has already been successfully carried out on a small scale for several years —as we learn from a recent communication of M. Zeidlitz to a Russian newspaper. It was an Englishman, Mr. Marr, who has inhabited Transcaucasia since 1822, who brought to a flourishing state the Crown garden at Ozurghety, and embellished it with a number of lemon, orange, and tea trees, these last numbering more than two hundred. After the Crimean war only twenty-five tea trees were growing in this garden, and, according to Mr. Marr's advice, they were transplanted to a private estate at Gora, close to Tchakhataour. Since the estate has changed its proprietor only two tea trees have remained; but still they continue every year to flower and give fruit, and M. Zeidlitz is sure that if the culture be seriously tried it might be successful in the valleys of the Koura and Riou.—*Southern Farmer.*

NO PHYLLOXERA IN SANDY SOIL.—M. Lalande, the Deputy and Mayor of Bordeaux, France, recently paid a visit to the principal vineyards in the south for the purpose of ascertaining the efficiency of the different modes of coping with the terrible phylloxera. He tested the effects of insecticides. He found the vineyard of Baboulet near Beziers, belonging to M. Jaussan, president of a syndicate for operating with sulphide of carbon, in a very satisfactory condition. He then visited six other vineyards, and everywhere found luxurious vegetation and abundant fruit. At Valantres the Comte de Turenne's property, where American shoots have been employed with great success, all the vines are heavily laden with magnificent grapes. At Aigues-Mortes M. Lalande found all the sandy soils planted with French vines in a flourishing condition, demonstrating the revolution which has resulted from the discovery of the impotence of phylloxera against a sandy soil. Lands which a few years ago would not have fetched 100f. (£4) a hectare, are now worth 10,000f. (£400).—*Exchange.*

FLAX CULTURE.—Some interesting facts have been gathered relating to this branch of agriculture in the United States. The culture has hitherto been much neglected, although it appears that flax and the various products of that plant can be cultivated in America quite as cheaply as in the various seed-producing countries of Europe. The imports of flax seed into the United States have reached as much as three million bushels in one year, the imports from India alone reaching 1,253,517 bushels in 1883-4, as compared with 558,249 bushels in 1882-3. The imports of raw flax into the United States during the nine years from 1871 to 1880 amounted to $10,987,549. The imports of flax manufactories during the ten years from 1871 to 1881 amounted to $177,747,371, or nearly $18,000,000 per annum. The average yield and prices of flax seed and wheat into the United States for the past ten years were as follows—wheat 12¾ bushels per acre, cost 93½ cents; flax 9¼ bushels per acre, cost $1 44c. It has been ascertained that with careful cultivation an acre of flax can be produced for $24 98c, this sum covering use of land, seed, and all necessary expenses. The receipts from an acre of flax are estimated to be as follows—9¼ bushels of seed, at $1 44c. per bushel, $13 52c.; 350lb. long fibre, at 10 cents. per lb., $35; 350 lb. flax tow, at 3 cents per lb., $10 50c.—total $58 82c. This shows a net profit per acre of $33 84c.—London "Times."

PEANUTS.—One of the most important industries of the New Virginia is the cultivation and preparation of peanuts. In the popular mind this unpatrician fruit is the product of North Carolina, whose citizens possess not only the descriptive name "Tar-heel," but answer to the euphonious title "Goober-grubber." Even in North Carolina, however, before the late war, peanuts were grown only in small garden-patches, and it was only because the Yankee soldiers learned to like them, and created a demand when they returned to the North, that the garden-patches have broadened into farm-fields. North Carolina never "caught on," however, and contributes almost nothing to the trade yet. The counties that lie in the Southeastern tidewater" corner of Virginia, however, adopted the culture of peanuts vigorously, and the product has multiplied five times during the last ten years. Virginia now sends to market over two millions of bushels annually, for which the farmers receive as high as a dollar and eighty cents a bushel in some cases. The crop is easy of cultivation on suitable soil, the yield very certain, and there is no waste. It is to be expected, therefore, that it will be tried outside of the limited region now occupied, in Virginia, North Carolina and Tennessee. The preparation of the peanut for market is carried on in factories, the most important of which are at Norfolk, where the fruit is graded, cleaned of dust and polished by steam machinery. Norfolk is the largest peanut market in the world except Marseilles. In Marseilles great quantities of African peanuts (whence ours are derived) are consumed by the makers of "olive" oil. The foreign nut has no market in this country, however, nor is any oil manufactured in the United States. It is said, however, that it would be a boon to cooks, if introduced, as a substitute for animal fats, especially in pastry.—*Hour.*

THE AMERICAN EVAPORATOR.

A trial was made on December 17th at Messrs. Carey Strachan & Co's Stores, Colombo, with one of the large No. 3 size evaporators, as to the curing of cacao beans. Considering the condition of the beans which had been three days in store, and that no one was present who was practically acquainted with the working of the machine, the result was, to say the least, promising. It appears that the temperature was somewhat too high, Mr. Vollar, who was unable to be present during the trial, stating subsequently that 120° to 160° Fahr. was the proper degree of heat for curing cacao beans. As our readers are aware, tea is cured at about 280°. We learn from Messrs. Davies & Co. that the machine which was tried this morning is to be taken by Mr. Vollar to Pallekelle to be there erected and fully tested, the experiments to be conducted and reported upon by Messrs. Vollar and A. Ross. Our readers may, therefore, expect a decisive verdict at an early date, and we see no cause to doubt that it will be as favourable as that which Mr. R. S. Fraser has already delivered. At our suggestion some peeled plantains were experimented on and slices of pine-apple were added. There can be no doubt that some of our fruits, mangoes amongst the rest, can be cured for keeping and transport by means of the Evaporator. One to be tried in tea-curing has been sent to Blackstone estate, and of its performanecs we hope soon to hear.

PRACTICAL PLANTING HINTS: THINGS YOU OUGHT TO KNOW AND WANT TO KNOW.

(From an old Hand.)

"How is it some tea estates realize a good average price all round for their tea?" Such was the question discussed with a neighbour the other day on his mentioning that ——— had realized a few cents short of a rupee per lb. for his year's picking. It was said, no doubt——— took exceptional care, and in fact lived in his tea house, but my friend said never a bit of it: the secret was he tasted every roll and if any were bad he chucked them away, and it paid him better to do this than spoil the name of his estate.

Those who are planting tea in old coffee fields where cinchona is also growing, should give the following a trial. Break all the branches off the coffee, and carry them off the field; leave the coffee stumps in the ground to throw out suckers, the best of which should be left to crop. Coppice the cinchona and allow suckers to grow. The *three* products will then have a fair start, and let us hope "grow in beauty side by side." This has been tried and after one year everything looks promising, and leaves an adjoining field where the tea was planted under the coffee and cinchona, nowhere. All who want to sail in a safe boat should try and keep the *three* products growing. Give them all a fair chance, and like a good father favour none. *Cultivate the soil* as high as you can afford and leave all the products to share it *pari passu* as the lawyers say. If it is ultimately found they cannot be grown together to pay, then knock out one or two if need be, but give the three a trial first. One year's trial, as has been said, is not discouraging by any means

Sinne Durais beware and *poor men* "pattiram." Don't believe for a minute what Talbot said about whisky being a necessity. It is nothing of the sort. Politically Talbot may be right but in other respects he is (tee) totally wrong. Ask him if he ever tried to do without it: if he has not, then what is his opinion worth? After some years trial my advice is "Hark to the teetotalers and 'way with them." Talbot does not make out such a good case for his whisky as the Irishman did when he mixed his politics with whisky. He said when addressing his audience, "and what makes you shoot your landlords?—whisky; and what makes you miss them?—whisky."

Just so my boys in Ceylon, whisky you *may feel* eggs you on for the TIME *being*, but depend upon it when the "shooting time comes" you will find you have "made a miss."

THE CEYLON FOREST ORDINANCE.

Draft of the proposed Ordinance relating to forests and waste lands and to the felling and transport of timber appeared in last Government *Gazette*. Its Indian origin is shewn by the use throughout of "the Governor in Council" which in India is significant of the fact that the members of Council have real and large, if not co-ordinate powers. Here the members of the Executive Council are in a very different position, and the Governor is bound to consult them only as specific laws render the process imperative. "With the advice of the Executive Council" is the usual phrase here. By the proposed laws the Governor will be vested with extensive powers in proclaiming forest reserves and we can only hope that the interests of the great planting enterprize will not be sacrificed to an exaggerated idea of the value of forests and timber trees. Conservancy and fresh production of really valuable timber trees are desirable, but a reference to Mr. Vincent's report will show how few of the timber trees of Ceylon come under this category. In the extensive planting operations which have taken place in Ceylon during the past half century the proportion of really useful timber trees destroyed has been very small and as for the effect of forest denudation on rainfall the most careful observations show it to be nil. We notice that besides Government forests proper, the Governor will have power to regulate village forests. We notice that amongst animals trespassing goats are charged only 50 cents against a rupee for cattle, two rupees for buffaloes and ten rupees for elephants. Now there can be no question that of all animals goats are the most destructive to forests, so much so that the opinion is held in the Madras Presidency that the paucity of forests in the lowlands of Southern India is mainly due to the ravages of goats. When these animals get at young forest trees the fate of the latter is sealed. Rights to forest land or forest produce, can be recognized by Government or purchased and all the stringent legislation of existing timber laws are to be consolidated in this Ordinance. The term "Headman" is, curiously enough, not defined, and the schedule of trees to be specially protected is not given. So that we cannot at present criticize the Ordinance as complete. Laws for the protection or for encouraging the growth of good timber trees in accessible situations are most desirable, but we feel bound to repeat the hope that the Governor of Ceylon and the various forest officers, (including Government Agents and their Assistants) will so use the large powers vested in them by this Ordinance as not to discourage and repress the planting enterprize, by acting on a too vivid idea of the comparative value of forests and timber.

TEA MACHINERY IN CEYLON.

It is unquestionably a great advantage in favour of the tea planters of Ceylon that at the commencement of the enterprize here, there should be available in the shape of labour-saving machinery the results of a couple score of years of experience and inventions by the Indian tea planters, with evaporators from America and appliances locally designed and manufactured. Last mail brought us letters and advertisements from the inventors and patentees of the two tea driers which we believe to be at present most in favour, Davidson & Co.'s "Sirocco" and Mr. Kinmond's Tea Drier. The agents of the former, Messrs W. H. Davies & Co., cannot certainly be charged

with neglecting the interests of their principale, as witness their recent "comparative" advertisement, in which they exalt the "Sirocco," with the most recent improvements, against all competitors for efficiency and cheapness. There can be no question as to the excellence of the "Sirocco" as a tea drier and it is not only cheaper in itself, than most competing machines, but being self-acting the cost of providing motive power is saved. Kinmond's Drier, on the other hand has the advantage for large "concerns" of getting through a great deal of work in a limited period. Colonel Money, it will be remembered, gave the palm to Kinmond's Dryer, which fact we did not fail to notice, in reviewing the latest edition of Money's work. But we felt compelled to say that it ought to be good and to do good work, considering its high price, apart from the necessity of providing motive power. Mr. Kinmond evidently took note of our remarks, for in his letter he writes :—

"I enclose a copy of my this year's circular referring to my dryers which shows a great *reduction in price*, thus :—

	No. 1 Dryer.	No. 2 Dryer.	No. 3 Dryer.
	£	£	£
Original price ...	150	220	300
Reduced ...	128	178	250

When the *quantity* of work these dryers can turn out is taken into consideration, they are by far the cheapest in the market, and the consumption of fuel in the most improved dryers is considerably under half a maund of green wood to one maund of pucka tea dried.

"As on a former occasion last year you wrote in the *Observer* about the *high price* of these dryers I shall be obliged if you will draw attention to the *reduction* in these *prices, &c.*, in the pages of the *Observer*. Jackson's new dryer which dries about 2¾ maunds tea per hour costs £360, exclusive of cost of packing and rail and post in England, that is £400, f. o. b. My No. 3 dryer dries 3 maunds per hour and costs £250 f. o. b. and require less than half a maund of wood to 1 maund of tea dried while Jackson's, according to his own circular, requires 2 maunds of wood to 1 maund of tea dried."

We leave this extract to speak for itself, while the local agents for the "Siroccos" will not fail to notice that their comparison now must be not between Kinmond's No. 1 dryer at £150 and the No. 3 Sirocco at £90, but between the former at £128 and the latter still at £90. The difference in absolute cost is, however, still considerable, apart from the expense of providing motive power, and the great questions which remain are as to comparative work done and fuel consumed. In both respects, it will be seen, Mr. Kinmond claims superiority for his machines over Jackson's. The Siroccos he does not mention, nor do the agents of these machines go into the question of fuel, which in some parts of India and of Ceylon as well, is a matter of much importance. We should be glad to receive and publish results locally obtained as to fuel consumed in proportion to tea prepared by the various machines now in use in Ceylon. They are, we believe,

Kinmond's Dryers
Jackson's ,,
Davidson's "Siroccos."
The American Evaporators.

The latter only just introduced and being tried. We are not aware that any of Gibb's and Barry's machines, or any others not enumerated above have been introduced into the island?

It is a curious fact that while Mr. Kerr has invented a roller and Mr. Gore has patented a very promising sifter, there has been no local attempt at a drier, if we except Mr. C. Shand's hot water machine? At this moment, Jackson's new and improved driers not having been tested in Ceylon, the favourite machines here are :

JACKSON'S ROLLERS.

[Thomson's challenge roller and Mr. Kerr's invention being also well reported of. We are not aware whether any of Kinmond's rollers are at work in Ceylon?]

KINMOND'S DRYERS.	Bracketted together as
DAVIDSON'S SIROCCOS.	No. 1.

Both are *very good*: Kinmond's being the better for large concerns, although as Messrs. W. H. Davies & Co. shew, three Siroccos can be obtained, or could be, for the cost of one large Kinmond at the old price. As yet Jackson's improved driers have to be proved in Ceylon, those on the principle of the Sirocco not being quite equal to the latter machine.

The Messrs. Davidson tell us that Colonel Money has expressed a very favourable opinion of their new-make "Siroccos," an opinion which he is to convey in one of his letters to the *Indian Tea Gazette*. We may expect, therefore to see what the veteran writer on tea and tea preparation has to say on the subject at an early date.

JACKSON'S SIFTER we know does excellent work and the trial of Ansell's machine was very satisfactory. The trial also of Gore's sifter and separators was very promising.

The local inventions for the withering of green leaf have been very creditable and very successful. So with improvements in the erection of Tea "Factories."

If we have omitted anything or made any mistakes, we shall be glad to be corrected.—*Ceylon Observer, December, 22, 1884.*

AMERICAN RUBBER TREES.

To the Editor Ceylon Observer.

Colonial Secretary's Office, Colombo, 23rd Dec. 1884.

SIR,—I am directed to transmit to you the annexed copy of a letter from the Foreign Office to the Colonial Office forwarding information in regard to South American India-rubber trees.—I am, sir, your obedient servant, R. H. SINCLAIR, for Colonial Secretary.

The Foreign Office to the Colonial Office.

The Under-Secretary of State, Colonial Office.

Foreign Office, Nov. 15th 1884.

SIR,—I am directed by the Secretary of State for Foreign Affairs to transmit to you, to be laid before the Earl of Derby, a despatch from Her Majesty's Consul at Rio de Janeiro respecting the cultivation of the India-rubber tree: and I am to state that Sir Joseph Hooker has suggested that the information should be communicated to the Government of Ceylon.—I am, &c.

(Signed) EDMUND FITZMAURICE.

Acting Consul Nicolini to Earl Granville.

British Consulate, Rio, 1st August, 1884.

The Right Honorable the Earl of Granville, K.G. &c.

MY LORD,—I have the honor to acknowledge the receipt of a despatch, Commercial No. 2 of the 22nd of March last signed by Lord Edmund Fitzmaurice, inclosing me copy of a letter addressed to Her Majesty's Foreign Office by the sub-Director of the Royal Gardens, Kew, referring to the cultivation, &c., of the Indiarubber tree, and instructing me to furnish your Lordship with the further information on this subject applied for by Sir Joseph Hooker.

The reason of my having delayed so long in answering your Lordship's despatch, has been that after full inquiry here, I was unable to obtain knowledge of whatsoever description regarding the information required, and consequently I addressed Her Majesty's Consular officers at Maranham, Ceará and Pará on the subject, and I have now the honor to enclose herewith to your lordship a memorandum received yesterday from the British acting Vice-Consul at Ceará, in reply to queries I requested he would kindly answer with reference to the cultivation, &c., of the Indiarubber tree as far as the province of Ceará was concerned.

On receiving further information from Maranham and Para, I will immediately forward same to your lordship. —I have the honor to be with the highest respect, my lord, &c., (Signed) E. NICOLINI.

Answers to questions as regards the production and

cultivation of the Indiarubber tree in the province of Ceará.

Query.—What are the names and productive qualities of the different kinds of rubber trees grown within your district?

Answer.—There are two kinds of rubber trees known in this province, first the "Manicoba" plant from which the Sernamley rubber is extracted, and secondly the "Mangabeira" from which, with the application of alum, the "Mangabeira" rubber is produced.

Q.—What is the extent of land under cultivation by said trees?

A.—The Manicoba trees are only cultivated to a very small extent on the mountains of the "Serra Grande" and Serra da Uruburitama, the greater part of the trees growing wild are over the mountains, at an estimated area of 20 leagues. On the Serras of Maranguape and Pacatuba many trees are to be found, but in this district they have not been cultivated. The Mangabeira tree grows wild in nearly every wooded district where there is a sandy soil.

Q.—What is the nature of the soil most favourable for the cultivation of the Indiarubber tree?

A.—The soil most suitable for the cultivation of the "Manicoba" plant is the clay soil of the mountains. For the "Mangabeira" the sandy soil of the low lands, especially towards the coast. The planting of the "Manicoba" is very simple either from the seeds or from slips of trees. The cultivation of this plant has not been much extended in this province, the people limiting their efforts to substituting any tree that may die by another from seeds or slips. Most of the planting has been done by nature, every year when the Manicoba fruit or seed is ripe it drops off the tree, and falling into suitable ground springs up without any care whatever been given to them.—(Signed) GEORGE HOLDEM, Acting British Vice-Consul.—Ceara, 18th July 1884.

THE LANKA PLANTATIONS COMPANY, LIMITED.

COFFEE; TEA; CINCHONA; CACAO.

REPORT

to be presented at the Fourth Ordinary General Meeting of the Lanka Plantations Company, Limited, to be held at the Offices of the Company, on Thursday, the 4th December next, at one o'clock p.m.

The Directors beg to submit their Report for the twelve months ending the 30th June last, together with the Balance Sheet and Accounts as audited, showing the position of the Company at that date. Your Directors regret that from the continued depression in all kinds of produce the result of the year has not been satisfactory, nevertheless the Company has made a profit of £2,639 15s. 3d.

The quantity of coffee shipped home was 5,373 cwts. against estimates of about 6,170 cwts.; the amounts realized and estimated give a total of £16,528 13s. 2d. The average price realized during the past year has been 61s 6d per cwt., whereas in the first year of the operations of the Company the average price was 73s. 6d. per cwt.

The Cinchona Bark harvested and shipped home, or in store, or sold in Ceylon has been 147,219 lb. From various causes (over which the Company has had no control) this has not sold well, the amounts realized and estimated giving a net total of £6,320 7s. 11d. only. An increasing return may be expected in 1884-85 and it is hoped that better prices will be obtained.

To the date of this Report 1,100 of the 2,000 of the 6 per cent. £10 Preference Shares offered to the share holders to enable the Directors to pay off the Ampittiakande mortgage for £10,000, and the Arnhall mortgage for £5,000, and for other purposes of the Company, have been allotted and paid in full. The Directors hope that the Shareholders will amongst them take up the remaining 900 shares so as to avoid the expense of offering them to the public. The Ampittiakande mortgage has been paid off and with the amount to be received from the unissued shares the Arnhall mortgage will be discharged. The preference shareholders for the time being, will have as their security the whole of the Company's estates which have cost £163,721 10s. 4d.

The cultivation of tea has been carried on, there are 525 acres planted, and this will be increased to about 600 acres during the season 1884-85: this of course involves a further small capital expenditure.

The cultivation of cocoa has made satisfactory progress; the Company has now 424 acres planted; 108 cwt. has been shipped home and has realized fair prices, and the estimate for 1884-5 is 350 cwt. India rubber is being tried and 40 acres of cardamoms will soon be in bearing.

The following statement shows the names, acreage, and cost of the Company's estate:—

Name.	District.	Acreage Coffee Cinchona, Tea &c.	Patna and Chena.	Forest and Grass.	Total Acreage.	£	s.	d.
Ampittiakande	Haputale	327	3	38	368	26225	5	0
Arnhall	Haputale	308	50	15	373	18521	6	9
Fruit Hill	Dikoya	237			237	10232	14	9
Fordyce and Garbawn	Dikoya	469		153	604	16149	2	0
Gonagalla and Parramatta	Dikoya	366	12	12	390	18185	12	11
Rappahannock	Uda Pussellawa	361	86	21	471	22846	10	7
Rillamalle	Maturata	199	14	37	250	1033[illegible]	11	9
Thotulagalla	Haputale	464	47	47	558	35143	13	1
Yattewatte	Matale	479	25	443	947	6083	13	6
						£163,721	10	4

The prospects for the Season 1884-85 are good. In a letter, dated 9th October last the General Manager states respecting Rappahannock that "without wishing in any way to exaggerate our prospects I can fairly say that the promise of crop is finer than it has been since the Estate was purchased by the Company and this is the case generally all over our places." Mr. White and Captain Hayes are the two Directors who retire, and being eligible offer themselves for re-election. Mr. John Smith, the Auditor (a Shareholder), also retires and offers himself for re-election.

By Order,
WILLIAM BOIS, *Secretary.*

8, Old Jewry, E. C., 21st November, 1884.

CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AND ENERGY.

Such a heading fifteen or even twelve years ago could only apply to an extension of the great planting enterprize of the colony in coffee. Subsidiary products were sneered at equally by capitalists and planters—by merchants and proprietors. The experiments so far made in tea did not promise much success, at least judging by the fields of the Ceylon Company Limited; while as to cinchona, who would care to invest time or money in covering any acreage beyond a mere patch, with a product only used medicinally? With middling plantation coffee ruling at over 100*s* per cwt. and the utmost confidence felt that proper cultivation would dispel the *Hemileia vastatrix*, then first coming into notice, why should a rupee be invested or an acre cleared for any other than the one great and profitable staple? Such were the questions or objections raised about "new products" a dozen years ago. We remember about that time urging caution, and calling on newcomers, then freely flocking in, to base their coffee investments on no higher estimates than 3 cwt. per acre of crop and 80*s* per cwt. of value—figures then considered ridiculously low, although now they may be regarded as maxima in connection with this branch of our planting industry. It may be calculated that between 1869 and 1877, there were no less than 3½ millions sterling introduced into Ceylon for the extension of cultivation apart from the outlay on plantations previously in existence. The fresh capital brought in, therefore may be said to have then averaged some £400,000 per annum. Since 1877, we suppose one-tenth of this sum would be

above the annual average, although the interest awakened in tea especially, has made a difference within the past three years.

It is our object now to show, as far as we legitimately can that Ceylon in its new products offers as good a field for judicious investments as any with which we are acquainted in the wide circle of British dependencies. We acted on this belief in writing the letter which the London *Times* published a few months ago and in answering the enquiries of the representative of the *Pall Mall Gazette*. With the same object in view we now begin the publication of a series of papers by planters of more or less prolonged local experience for the benefit more especially of many persons outside the island who, at this time, are looking to it for the investment of their energy and money. Although there are at present several indications of capital becoming more generally available for local use; yet the influx has to continue freely if progress is to be made with tea at the rate justified by the success hitherto attained on most, if not all, our tea plantations. There is therefore plenty of room for drawing further attention to the subject. Tea among all new products, is of course the most generally believed in and the most promising, because of the hardiness of the plant and the varieties of climate, soil and altitude in which it is found flourishing. Cinchona and cacao although very valuable—in fact the more valuable perhaps from one point of view, when fairly established,—have a far more limited range and the planting of them involve a good deal more risk. Some of the advantages of tea over coffee as an investment are found in the longer duration of crop time, the greater independence of climatic conditions and the steadier employment afforded to a certain labour force all the year round. The whole year's labour of a planter over his coffee fields was occasionally rendered valueless by unpropitious weather prevailing for one month or six weeks when the bushes were ready to burst into, or to mature blossom. Again a coffee planter would come to Colombo to get advances on crop, estimated to be gathered six or nine months after date according to the blossom. The tea planter, as in the case of one whom we saw the other day, comes to an agent for an advance on the security of crop gathered month by month. "I dont' want money"—as our friend said to his agent —"to be repaid out of next year's crop; but an advance which I shall begin tomorrow to pay off by sending you leaf for shipment, my picking going on steadily month by month." There is no doubt of the additional safeguard for capital which this fact gives in the case of tea over coffee investments. It is further urged that a tea clearing can stand neglect, a temporary stoppage of expenditure, without the permanent injury which was too often sustained under similar circumstances by coffee; while in the event of severe competition between India and China bringing down the price for a time to a point that allows no margin of profit, the Ceylon tea planter could suspend outlay without injury until the crisis was over. In the case of coffee (or any fruit crop), of course, the berries must be picked when ripe or finally lost. As regards tea in India and Ceylon, enough has not been made perhaps of the greater economy with which tea can be transferred from the Ceylon plantations to the London market. The intermediate charges in Colombo are decidedly less than in Calcutta.

But there is no need that we should further stand between our readers and the Papers we have referred to. We publish No. I today, and will give the others at intervals of two or three days. We think it will be found that the subject is treated with sufficient variety. Some of our correspondents have thrown their observations into Letters addressed to enquirers at home; others will give their experiences in an almost autobiographical form; while one writer will tell us "How he kept his wattie" all through the bad years. Notwithstanding many disadvantages the last-mentioned gentleman made his coffee pay working expenses and interest; and more, to cover the cost of planting cinchona which in its turn yielded funds sufficient to enable most of the land to be turned into a tea plantation; and this again is now valued at more than ever the coffee wattie was. But enough of reference to the several Papers which will tell their own story all in good time:

THE PERIOD OF PLANTING DEPRESSION DRAWING TO AN END—OVER-SPECULATION IN TEA DEPRECATED—SALUBRITY OF CEYLON TEA DISTRICTS—PROSPECTS BEFORE INVESTORS: TWO COURSES—FORESTLAND *vs.* OLD ESTATES—CAPITAL REQUIRED—PROBABLE OUTLAY AND RETURN—UNDER JUDICIOUS INVESTMENT, 20 PER CENT ON CAPITAL.

It is generally conceded by those who have long resided in, and are well-acquainted with, the island of Ceylon, that the period of depression which has overtaken this country is coming to an end, and that a period of comparative prosperity may be confidently looked for in the immediate future. The failure of the coffee enterprize has been a severe blow to the Island, and one from which, not so long ago, it would have appeared inconceiveable that she could ever recover. Now, however, it is becoming more and more vident everyday that through the extension of the tea enterprize a fresh era of prosperity is at hand, and one it is to be hoped that will prove of lasting benefit to the Island.

Over speculation, and the hasty and ill-considered expenditure of money in unsuitable land, will, it is to be hoped, be avoided for such can but lead to disappointment in the future as it has in the past. The judicious investment of capital in the tea enterprize by those resident in the Island who have profited by the experience of past years, and by new colonists of the right stamp, is an event to be hoped for, and one deserving of every encouragement. Whether a period of *speculation* in Ceylon tea is about to occur or not, it is difficult to say. What has happened in the past may occur again; in the immediate future we have, however, to look for an influx of capital into the Island, which will render much of the land at present unproductive, profitable, and give remunerative employment to many who are now suffering from a period of depression which affects either directly or indirectly every individual connected with the planting industry. The general salubrity of the Ceylon tea districts is well-known, and the advantage which this gives us over our Indian brethren is proverbial. Any one unacquainted with the European residents in the Island would be astonished at the number of robust men who have already passed the better portions of their lives in constant residence here, and who are probably in better general health than they would have been had they never left England. Some of the lowcountry tea districts are in parts rather trying to some European constitutions, but even these districts (which are becoming more healthy every day as the country gets opened up,) are as a rule better than the other tropical colonies which offer inducements to investors. The hill districts, which comprise the large bulk of the existing tea estates, as well as large tracts of land suitable for tea, afford as pleasant and healthy a place of residence as can be desired.

Proposing investors in tea have two prospects open to them: they can either purchase forest land in localities which have not been found suitable for coffee, or they can obtain estates which have been planted with coffee, and either abandoned or cultivated as the case may be. As a rule, the soil of the districts at present in forest is inferior to that of the coffee district, but

on the other hand its fertility has not been affected by previous cultivation. The soil of coffee estates that have not been badly affected by wash appears admirably adapted to tea cultivation in most cases, as the roots of the plant, which is a very deep feeder, are able to tap stores of nourishment left untouched by coffee.

The suitability of the Ceylon climate, with its abundant and evenly distributed rainfall, for the production of leaf, need not be enlarged upon; the advantages we possess in that respect are well-known. In the wet portions of the lowcountry the climate is very forcing, and causes a growth which is remarkable in what apparently seems a poorish soil. Hence, earlier returns may be looked for in such districts, and with this is joined the advantages of cheap production. Such land, being in all cases jungle, requires of course more capital to bring it into cultivation than coffee land.

On the hills in almost every case the only land available is that which has at one time or another been in coffee. If recently abandoned the cost of clearing such land is great: abandoned coffee of old date here showing a considerable advantage. In the case of cultivated coffee, however, much of the cost of putting the land into tea will be covered by the crop from it, whilst the cost of felling, roading and draining, and in most cases the erection of lines, bungalows and stores is avoided. Under such circumstances, the conversion of a coffee estate into a tea-garden becomes an undertaking requiring a comparatively small outlay of capital, apart from the original purchase.

R250 per acre should be amply sufficient to bring a tea estate into bearing, where the original purchase has been that of a block of forest land. Such land can now be procured for about R30 per acre and upwards. Where a coffee estate has been purchased a far smaller sum will suffice: the exact amount will depend on the thoroughness with which the land has been originally opened, and the extent to which the old product assists towards the introduction of the new.

A capital of R60,000, or say £5,000 sterling, should be sufficient to bring into full bearing, with all the necessary machinery and buildings, a tea garden of 200 acres, allowing also for the purchase of a reserve of timber. A garden of this size, if care has been taken in selecting the seed, and if the soil is fairly good, should give a continuous yield of 400 lb. per acre, costing from 30 to 35 cents per lb. (according to circumstances) to put in Colombo, and netting at present prices 60 cents.

Low prices are, at the present moment, the burthen of most reports regarding Indian Tea Companies. The margin between cost of production and sale price is, just now, at the very lowest point compatible with the realization of a fair dividend; many concerns, in fact, yield no dividend at all under the present circumstances. Allowing, therefore, for a further fall in prices of 10 cents per lb., one which would have a serious effect upon many of our Indian friends, we still have a margin of profit of 15 cents per lb. or R60 per acre. This on a 200 acre estate, costing R60,000 to bring to a bearing age, shows interest at the rate of 20 per cent on the invested capital.

In the cases where coffee estates are purchased for conversion into tea gardens each investment must be considered on its own merits. As a rule such investments offer great inducements to capitalists, for the returns from coffee and cinchona will usually go a long away towards meeting the cost of planting with tea, whilst the prices at present ruling for such land are very low.

In the foregoing letter I have not thought it necessary to support the statements made by any proof, nor has space allowed any entry into details: abundance of such are at the command of any one who is desirous of enquiring closely into the subject. My object has been to shew briefly the inducements which Ceylon now offers for the investment of capital in the tea enterprize, and to illustrate the fact that the present moment affords opportunites which may not for long be so readily offered.

T. C. OWEN.

CALCUTTA TEA SYNDICATE.

CALCUTTA, 1st Dec. 1884.

DEAR SIRS,—The last circular issued by the Committee was dated the 31st July 1884, and since then there has not been anything of importance to communicate until now, when more satisfactory advices have been received, which the Committee wish to place before you in the hope of encouraging further shipments to the new markets which have been opened out by the Syndicate.

AUSTRALIA.—Messrs. James Henty & Co., in their letter of 22nd October, advise the sale of two breaks of tea shipped by the Syndicate per steamer "Bucephalus," at a price equal to about 3d per lb. over the London valuations put upon the teas here at time of shipment, and they say that at the same auction some 600 packages sold exceedingly well and left a handsome profit to the importers. The biddings were brisk, and the prices obtained were 1s 9½d per lb. in bond for medium orange pekoe, 1s 3d to 1s 8d for pekoes, and 1s 2d to 1s 4½d for pekoe souchongs.

They strongly recommend further and full shipments of Indian teas, and they say that small quantities packed in whole-chests would meet with a ready sale; but as the market for these large packages has proved so precarious, the Committee think it would be prudent to confine shipments to half chests of 38 to 40 lb. nett.

It is satisfactory to find that the exports to Australia and New Zealand during the past two months have amounted to 400,000 lb., and that the total shipments to these markets compare favourably with those of last season.

AMERICA.—Messrs. John C. Phillips & Co., the New York Agents of the Syndicate, write, under the date of 12th August, that Indian teas are certainly better known and more generally used each season, and from what they can learn they think the number of mixers is steadily increasing. In a subsequent letter these friends say that Indian teas are well enough known now to lead to a rapid increase in their consumption if supplies from China were seriously interrupted in consequence of the hostilities between that country and France.

As regards the future demand, they write on the 14th October that they think their market is prepared to take an increasing supply at steady prices; but without regular shipments somewhat in excess of the demand, the enquiry for Indian teas will not extend but will die out again gradually.

In this view of the matter, it is disappointing to find that the exports to New York have fallen off considerably as compared with those of last year, but it is hoped that the trade will not be allowed to languish for want of further support.

NORTHERN EUROPE.—The Committee are happy to be able to say that a very fair quantity of the present season's tea has been received for shipment to Amsterdam. Judging from sales already advised, it seems probable that fully London prices will be realized for all suitable qualities, provided the demand for Indian tea in Holland is progressing in proportion to the increased despatches from this side.

The shipments of the Syndicate since the 1st May have been:—

To Melbourne.	To New York.	To Amsterdam.
23,890 lb.	25,644 lb.	30,395 lb.

And the total exports from the same date to the 30th November from all sources have been:—

To Australia and New Zealand.	To America.	To Amsterdam.
569,453 lb.	30,738 lb.	32,255 lb.
Against last year—		
206,536 lb.	101,831 lb.	1,800 lb.

—Yours faithfully, A. G. WATSON, *Honorary Secretary.*

"TROPICAL AGRICULTURIST," VOL. III.

(A Review.)

Judging from the numerous testimonials received from all parts of the globe, the *T. A.* has evidently obtained a world-wide reputation. Practical agriculturists from all parts of the compass trumpet forth its praise. Thus, from the north, Mr. W. T. T. Dyer, F.L.S., C.M.G., dating from Kew Gardens, Dec. 1883, writes:—"Sir Joseph Hooker and myself always look out for the successive numbers of the *T. A.* with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed." From the south, the editor of the *Australasian* writes:—"This serial is quite a cyclopœdia of tropical agriculture." From the east, a correspondent from the Wynaad writes:—"The *T. A.* is highly appreciated by all who read or have read it, and one and all declare that it supplies a long-felt want." And from the west, Mr. D. Morris, F.L.S., of Jamaica, writes:—"I sincerely congratulate you on the *T. A.*, which supplies a great want; I only wish that we had in Jamaica a paper like yours to work up planting subjects."

The third volume (1,090 pages) as full of information for the people "as an egg is full of meat," well sustains the reputation of the work. This volume derives additional and special importance from the fact that it includes Mr. Vincent's valuable and exhaustive report on the "Forests of Ceylon." The clear and well-executed Map of the Island which accompanies this report is well worth the price charged for the whole volume.

At this epoch of our agricultural history, TEA, the hope of the hitherto despairing planting world, naturally occupies the first place in the present volume. No less than 325 articles—many of which are of considerable length and of unusual interest and importance—notably those by Mr. Armstrong, pp. 250-7; Mr. Owen pp. 273-8, and Mr. Hay pp. 383-7, being devoted to the discussion of this valuable product.

Coffee is discussed in		164	articles

I. THE CULTIVATION OF TEA.—Planters who would "turn the corner" will do well to study these pages, and then, having made up their mind as to the most suitable soil and climate, and as to the best jât, let them fall to and "fell" and then "peg" away at tea. Our old friend (p. 61) who formerly wrote lamentable accounts of the ravages of crickets, white ants, etc., now confesses himself to have been beaten "all along the line," so far as his efforts to grow cacao and Liberian coffee are concerned, and having himself become a tea-totaller, advises planters on all sides to forswear all more doubtful products, and addict themselves to tea. Sound advice my friend, and may your bushes flush, until you yourself are flush of all good things.

(1.) *Climate and Soil.*—Mr. Armstrong (p. 252) speaks of the Kelani Valley District as having the beau ideal of a tea climate. If the report is true that the Government have resolved to reserve the greater part of the Crown forests, in this district, land from Hanwella upwards already in the hands of private parties should be invaluable, when the anticipated "boom" comes. In the coffee districts, land which is "most suitable for coffee" is declared to be "most suitable for tea." The planting of tea on old washed coffee land is deprecated. "Where coffee makes most wood (called leaf in tea) there will our tea do best."

(2). *Jât.*—This subject is discussed on p. 133-4. "Indigenous Assam" or a hybrid closely approaching it in character is recommended as best for Ceylon. The indigenous if used at all must be confined to lowcountry estates. Mr. Armstrong also (p. 252) insists upon the importance of obtaining seed from the "highest class hybrid." Mr. Owen (p. 274) says:—"In India none but indigenous seed at R150 per maund is bought, and on the hills a good high-class hybrid is gone in for. He then warns Ceylon planters against planting China or low-class tea at any elevation. Inferior jât means decreased yield and a comparatively weak tea (see also Mr. Hay's remarks on this point, p. 383). Thus, the *T. A.* finally settles the important question of jât.

(3). *Yield.*—Mr. Armstrong—page 255, speaks of Gallebodde and its 800lb per acre and the older portion of Dunedin with its 730 lb. He also mentions a field of his own—3 acres at 7½ years, which has given 1,200 lb!! I should think therefore that the average of 400 lb. for up-country and 600 lb. for low-country estates may be accepted as correct. Abbotsford has already reached 663 lb. See Mr. A. M. F. jnr's. letters pages 424 and 789. [Average 500 lb. for the year.—ED.]

(4). *Profit.*—S. on on page 383 works out a table of profits to be expected from tea from which we learn that an average yield of 400 lb. per acre will give a profit of R120 and that an average of 600 lb. will give a profit of R200. For every 50 lb of tea add R20 per acre and for every 1d. improvement on 1s 3d. add R5 per 100 lb. yield. S. cannot be very far out when he states that with tea up to 1s 10d. to 2s. per lb. good estates will be worth R1,200 per acre.

II. THE CULTIVATION OF COFFEE.—An interesting paper on this subject by Hon. J. L. Shand, pages 176-8, will amply repay perusal. The Report of the "Spring Valley Coffee Company" p. 73, speaks very hopefully of the prospects of coffee in Uva. The Manager answers the Directors that with plenty of manure there is little to be feared from leaf disease. Mr. Storck, p, 350, recommends the expenditure of £2 10s. per acre on his vapour cure. No, thank you, Mr. Storck, no more vapouring please. It is rather late in the day to tender us such advice, we mean to stick to manure as they do in Spring Valley and if that does no good, we shall addict ourselves to tea.

III. THE CULTIVATION OF CACAO.—An instructive paper on this subject appears on pp. 371-4. Intending Planters will note that the very best land that can be got should be secured for cacao. An estimate is given for opening and bringing into bearing 200 acres, from which it appears that the total cost for 6 years (including interest on outlay) will be R107,946. The crop however of the 3rd to 6th years is estimated at a total of 2,800 cwt. which at R45 will realize R126,000, or R16,050 clear gain, plus an estate worth R140,000 or a total R156,050, on six years' work!!!

IV. COCONUTS.—Articles on this produce will be found on pp. 609, 772 and 819. In Fiji Coconuts are said to be in full bearing at the 8th year; in Ceylon double that time should be nearer the mark.

V. GENERAL.—Mr. Morris (pp. 746-55) writes a most interesting article on St. Helena. Elephants are dealt with on pp. 870-77. Astriches on p. 861, Sugar by G. W. on p. 659, Nutmegs on p. 656, Paddy (rice) by Mr. Weerakody on page 785, Oranges on p. 74. On p. 891 we have a chat about Ceylon fruits, in which our oranges are grossly libelled. Some years ago Mr. R. L. M. Brown planted a small orange estate at Mahara, perhaps Mr. Brown would *pro bono publico* let us have the result of his unique experiment.

Scattered throughout the pages of this most interesting volume are papers on very many other interesting and important topics. I cannot dwell upon these just now, so beg to refer your readers to the book itself, where they may "enquire within" about everything (agricultural) for themselves.

NIREFONOS.

TEA IN AMBAGAMUWA.—Aberdeen estate, Ambagamuwa has been recently reported to have given for the season nearly as large a yield of leaf as Mariawatte. The manager answers our enquiry as follows:—"How could you expect to hear from one who has not yet got the proper average for his tea? When I can double the price it will be time to let you know the whereabouts of "Aberdeen Awa." Meantime, it's no use disgracing a *rising district* with a bad name. My own opinion is that Ambagamuwa will yet stand second to none for quantity as well as quality of tea produced in Ceylon. Some of the district estates—Benachie for instance—have a fine lay of land, good soil, perfect aspect, catching the first glimpse of the rising sun, and so far started with a good jât of tea, which I have no doubt will add more to the future success of a good tea estate than people are aware of at present. My ideas coincide quite with your correspondent 'R. L.' from Assam about *jât* and *hybrid*. Figures of quantity (clearing planted in 1879) will follow at end of this month."

Correspondence.

To the Editor of the "Ceylon Observer."

THE DEMAND FOR COCA.

LONDON, E. C. Nov. 21st, 1884.

DEAR SIR,—I have written to you and many of the planters in Ceylon upon the great value of coca (*Erythroxylon coca*).

We have held considerable quantities of this leaf, and the extracts and alkaloids prepared from it have given such excellent results that the demand has increased to such an extent that we are nearly sold out of stock.

The samples that we have received from India have arrived in the form of a dark brown burnt-up leaf with an appearance of their having been dried in the sun. We had them tested for alkaloid and could find hardly a trace.

If the leaves can be sent over in the state of the sample I send to Dr. H. Trimen by this post, they would command upon this market from 3s 6d to 5s per lb.—I am, yours faithfully,

THOS. CHRISTY & Co.

P.S.—E. M. Holmes read last night at the Linnæan Society a paper on a "Ledger cinchona" that has flowered at Mr. Howard's at Tottenham.—[Mr. Christy has sent us a sample of coca leaves which can be seen by any one interested.—ED.]

COCA: THE NEW ALKALOID COCAINE.

LONDON, E. C., Nov. 28th, 1884.

DEAR SIR,—You no doubt see the *Lancet* and *British Medical Journal*. In these papers you will find this week an account of the great work that has been done with *cocaine* which is produced from the Erythroxylon coca leaves.

You are well aware how I have urged the planting and introduction of these trees, and in the *Lancet* you will observe that an idea is held out that it will be impossible to furnish an adequate quantity of the leaves for the manufacture of the alkaloid. It is most important that you should at once disseminate the information that it is quite useless to send home the leaves in a brown, withered state. It will be necessary in my opinion to treat them perhaps by slight fermentation, then by drying them on a kiln, and they should be sent home by the most expeditious route. There is no duty on them, and if, they were here today, they would fetch, if in first-class quality, such as the sample sent you last week, 5s per lb. if not more.

You will observe at the end of the *Lancet* a promise by the editor to furnish the information respecting the action of cocaine in *dentistry*, within a week or so.

I promised to send you the particulars respecting papaïne, but I only received the detailed information last night, By post today I send you a small quantity of the powder which you are at liberty to hand over to any of your hospital surgeons; it is guaranteed to dissolve 1,000 times its weight in fibrine. When I tell you that the finest sample we have ever had from Ceylon will only dissolve about 10 per cent, so you see there is a long way to fetch up. We have had papaïne from other places which dissolves up to 300 per cent.

Professor Finkler, knowing that I had introduced papaïne, sent over a relative to beg me to take the representation for England, her Colonies and America, and, as soon as his document is printed, a copy shall be sent to you showing the immense value of this drug.—I am, yours obediently,

THOS. CHRISTY.

"BAD SEED AND BAD PLANTS."

5th December 1884.

DEAR SIR,—A few months ago I wrote several letters to the *Observer* on the subject of "Tea Jât," in the hope of provoking a discussion on a subject of much importance. Planters were either deaf or indifferent; but your senior editor, recognizing the necessity for more light, came to my aid with valuable extracts and articles. Your correspondents "S." and "R. L." now re-open the discussion, though too late, probably to save many from much useless work and outlay. We all know how prone even one year old plants (of the worst jât) are to blossom and seed. Is not the temptation great to dealers in seed to gather these seed of seedlings to meet the demand made upon them? I have always suspected them. Verb. Sap. But I believe in *hybrids*. But as regards "S.'s" conclusions respecting the coffee-leaf-disease, I must be excused if I conclude that he does not arrive at them from sufficient scientific data, but jumps to them. The trees upon which the fungus first appeared were not weakly things, and if they are not as vigorous now *as any in the country* (has "S." made any enquiry respecting their recent or present condition?) it is, I think, rather in consequence of cinchona than of *Hem. vast.* I believe this pest to be new in Ceylon and in a given time fatal to the coffee plant whatever its origin and however good. Bad seed will produce bad plants which by speedily dying out will be their own cure. C. S.

RESTORING COFFEE BUSHES BY CAREFUL CULTIVATION—WILL IT PAY ON A LARGE SCALE?

Dimbula, 11th Dec. 1884.

DEAR SIR,—Here is the result of the restoration of 100 coffee bushes; six bushels of cherry, trees looking fresh and green will give more next crop. Almost every acre in Dimbula would be as productive with the same mode of cultivation.—Yours truly,

J. HAWKE.

[What mode and at what cost?—ED]

WANTING TO KNOW ABOUT VARIETIES OF CACAO.

12th December 1884.

DEAR SIR,—As one interested in cacao cultivation I should be much obliged if you or any of your correspondents would inform me whether the names "Caracas" and "Forastera" are peculiar to two kinds; or whether they are general terms applicable to two classes, each of which may embrace several varieties; or whether the two words are synonymous.

In other words—am I perfectly safe in purchasing anything that is guaranteed to be either one or other?

ONE WHO WANTS TO KNOW.

CARDAMOM CULTIVATION: A QUESTION FOR MR. OWEN.

12th Dec. 1884.

DEAR SIR,—When cutting out, this morning, a large clump of cardamoms (some 4 feet in diameter) to be divided into bulbs for planting, I found in the centre a large quantity of racemes covered with fine well-formed fruit-pods. These were quite invisible from outside while the clump was standing, and equally inaccessible on account of the crowded stalks. Is it always the case that a large percentage of the fruit is thus wasted when the plants have attained to a large size, or should they be thinned out so as to bring all parts within easy reach?—G. E.

THE SWEDISH PLOUGH INTRODUCED INTO RICE-FIELDS AT HANWELLA.

Hanwella, 20th December 1884.

DEAR SIR,—Although agriculture in Ceylon has been long neglected, yet no native has ever thought of improving its mode, but follows his ancestorial plough.

However, it is a great treat to see that Mr. G. E. Ameresekere is endeavouring to impress on the minds of poor gowiyas the advantage of the new plough.

He has brought over here a Swedish plough and tries it for owita ploughing, with success so far, since Saturday last.

There was a great gathering, some of them came even from a distance of 10 to 12 miles to witness the first start.

Many of them condemned the plough, at the first sight of it, as they always do, but Mr. Amarasekare explained to them with great patience the numerous advantages that is to be derived by the use of it. He is of opinion that when his plough-men and cattle are well-practised, one new plough will beat the work of ten native ploughs. Perhaps you are not aware of that before the seed paddy is sown in an "owita" land, the poor gowiya has to give it ten ploughings the least, still not a single furrow deeper than half-an-inch. But the new plough will clear away any "owita" land; however, it may be of use in two ploughings of two to three inches deep. Thus you will understand Sir, how, advantageous is the new plough to native cultivators if they will only try. Our heartfelt thanks are due to Mr. Amarasekare, for the trouble he takes to introduce the new plough. In wishing him all success we trust that others who can afford will follow his example.—I am sir, your obedient ervant.

GOWIYA.

THE CACAO in Dumbara has not recovered sufficiently from the last drought to place it in a position to stand another. In fact, some of the trees will be severely enough tried if the weather in January, February and March is, as it ought to be, fine and dry. *Helopeltis* on some places; none on others.

THE AMERICAN EVAPORATOR FOR CACAO.—Messrs. W. H. Davies & Co. write:—"You will be glad to learn that a No. 2 machine, at Messrs. Geo. Steuart & Co.'s mills, was on Saturday tested with cocoa, by a well-known Matale cacao planter. About seven bushels of cocoa were dried in 1½ hour, from time of firing to finish, and the machine is described as an 'undoubted success' and the 'best drier in the country for cocoa.' Two men can easily work it, and there seems little doubt about its capabilities for drying tea, especially the larger size, No. 3. Wood was used, and very little was required to obtain the desired heat. Indeed, the experimenter is so thoroughly pleased with the performance of this small machine that he has decided to go in for one of the largest size capable of turning out 12 times the quantity of the No. 2."

THE ABERDEEN TEA PLANTATION, in Lower Dikoya or Upper Ambegamuwa, is shown by the Superintendent to have yielded as follows since it came into bearing:—

"The clearing was planted at the latter end of 1879; plants distance apart 3 × 2½.

Yield	1882	450	lb.	made	tea
„	1883	735	„	„	„
„	1884 over	1,000	„	„	„

"In August, September, October, and November, 1883, this tea was made along with tea from bushes of same age and realized an average price in London during the 4 months of 1s 5¾d. Since then it has been made along with the other ⅞ths of the estate, two years and under, and only plucked once a fortnight and over, according to circumstances. I may mention that about ⅛rd of the field in question is of very poor soil, and on this portion a large percentage of the plants died in 1882 from white-ants or othercauses."

But financial success, or at any rate profit, does not depend on large production only and many argue after the fashion of a very sagacious planter whose practical hints elsewhere deserve careful consideration, that a medium yield with careful preparation, (the rejection of bad "rolls" even) and a consequently high average price will prove more profitable in the long-run. The one bugbear before us at present is a possible scarcity of labour for all the requirements of tea planters; but this cannot last long when the Tamils in Southern India fully learn that rupees in prompt payments are to be earned for honest work in Ceylon.

CINCHONA BARK UP!—A good authority writing by the English mail of Nov. 28th states:—"It is rumoured that the cinchona market, to be held on December 2nd, is to be the best sale since the stoppage of the Milan firm" On the top of this comes the telegraphic news that quinine is up 1½d the unit in London.

SUGAR CULTIVATION IN CEYLON.—The editor of the *Australian Tropical Planter* writes us:—"Sugar is very 'dicky' here; but I think the price of sugar is at lowest ebb as the Europeau Bounty system cannot last, as it is just bolstering up an unprofitable industry. I hope your coffee crops are not complete failures. I do not agree with the correspondence in *T. A.* that sugar will not pay in Ceylon. Since it was tried new machinery, chemical process and tramways, should make cane sugar pay well—you have got such cheap labour and great chances to rrigate."

ARECANUTS: THE SHEHRIWADUN VARIETY.—As our readers will have seen from the advertisement, Mr. Creasy gives a high character to this new variety of areca. He says:—

The excellence of the nut consists in the large proportion of the white fleshy part of the inside, and this *cures white*. At the same time it is close-grained standing curing and export well which the Hamban, Rata and other poaks do not. These nuts in India fetch a much higher price than any others, being of a far finer flavor to connoisseurs. The variety is only known in one neighbourhood of a native State in India.

The planting of arecas in likely to attract special attraction from Europeans in Ceylon erelong and we are promised a paper on the subject from a gentleman who has had experience of this product.

QUININE MADE BY MR. AUFFRAY.—It is only a few days ago that on seeing that R110,000 was paid yearly for the quinine imported into the Colony, we said that if we could make our own quiuine, it would be so much saved to the Colony. It appears that the problem has been solved by Mr. Auffray, a person employed on an estate at Grand Port. Mr. Auffray from the bark of quinquina, has produced sulfate de quinine. This deserves more than an honorable mention, it deserves a good reward. And he has succeeded in doing it with the utensils the most primitive possible. We have to thank Dr. Chanvin for letting us know the fact. In spite of the "*nothing but sugar doctrine*" of some papers—we perceive that many are turning their minds to new culture &c.,—we have Bagasse paper and quinine just come to light; the impulse is given, the idea will progress.

"THE YATIYANTOTA TEA COMPANY, LIMITED," is the heading of a long Memorandum and associated Articles in last Friday's *Gazette*. Such announcements, some years ago, in the days of our prosperity, appeared almost too frequently; but it is a considerable time now since we have had to chronicle the establishment of a new Plantation Limited Company in Ceylon, and this may be said almost to mark a new departure, and let us hope to indicate the early approach of a time of greater confidence and activity. As already announced, the Yatiyantota Company take over some 556 acres of land belonging to the late Mr. J. H. Young, and they take power to clear, cultivate and develope the same, also to purchase or lease adjoining lands, and to purchase tea leaf or other raw products for the manufacture, manipulation and sale. The nominal capital is R100,000 divided into 100 shares of R1,000 each and the subscribers include the following well-known names of local gentlemen:—W. H. G. Duncan and Charles Young, each 10 shares; A. Thomson, Jas. Anderson and Jas. K. Morrison, each 5 shares; D. Edwards 3 shares; G. W. Carlyon 1 share. We wish the new Company all the success its directors and shareholders can desire.

THE "T. A."—A planter writes :—"Kandy, 16th Dec. —I feel very much interested in the *T. A.* I like it very much indeed, and only wish I had had it from the beginning, this I would have done too if I could have afforded it, but circumstances, not my will, have seen fit to step in and ordain it otherwise."

TEA of very good quality is said to be grown at the Andamans. A small supply received at Rangoon met with ready sale. It is thought that if tea is more extensively grown and manufactured in the convict establishment, the demand among the Burmans will soon set in. China tea up to the present moment is largely consumed in Burmah.—*Madras Standard.*

TEA MACHINERY; KELANI VALLEY, 14th Dec.—With reference to the notice that appeared in your issue of the 12th instant, referring to Mr. "Gore's Tea Sifter" I understand that a like delay in putting out of hand Mr. "Kerr's Tea Roller" is taking place.* Messrs. Walker & Co. are not in a position to manufacture the machines of either of the above gentlemen, owing to some arrangement come to between them (Messrs. Walker & Co.) as Messrs. Jackson's agents for Tea Machinery in this country, and the Government Factory are rather slow.

TEA.—The *Indian Tea Gazette* claims "that India is now not only master of the situation as regards excellence of quality, but that, in the matter of price, also, we are gradually becoming *conquering* competitors. An old vested interest like that of China takes a long time dying; but dying it surely is, and it only needs that we should still persevere and persevere in enhancing quantity (out of a like area,) while still maintaining quality; reducing to the lowest safe minimum production cost; availing ourselves of all the knowledge around us which can in any way be utilized for our advantage; and joining 'hip, heart, and hand' with our brethren in the tea industry in any and every way that may conduce to the general good."—*Madras Mail.*

JAVA—The *Locomotief* of the 22nd Nov. reports the price of sugar in Java to be steadily falling with every prospect of becoming lower still hereafter. It is no better with quotations for coffee, though for a while a slight improvement was manifest on the strength of rumoured short Brazilian coffee crop this year. The Netherlands India Commercial Bank, when on the point of suspending payment, which would have brought about a widespread mercantile crisis, succeeded in warding off the danger by raising a loan amounting to nine millions of guilders, and making over the estates under its management to a newly started planting company in return for its co-operation in advancing the above amount.

IN DELI, of late, on several of the smaller estates, the planters, to save the expense of employing coolies, have been letting their land to Chinese tobacco-growers whom they supply with seedlings or small advances in order to buy up from them the crops so raised. The Deli Planters' Association on the ground that these small growers might prove dangerous, as receivers of stolen tobacco leaves from the regular estates, has decided upon forbidding this letting system among its members. The Batavia *Dagblad* deems this decision a wise one on wholly different grounds, basing its opinion on experience gained in Java where the system of landholders buying up tobacco from small growers instead of cultivating the article on their own account has been baneful to tobacco cultivation there, by keen competition among buyers in furnishing higher and higher advances to growers, or in the buying at high rates tobacco for which others had given advances or seedling. The latter form of dishonesty has proved ruinous in its consequences.

* Mr. Kerr, we believe, has several orders now on hand waiting to be attended to for customers.—*Cor.*

JAVA, 20th DEC.—The Samarang *Locomotief* of the 15th Nov. states that this year's sugar crop in Java is an overflowing one. Thus, on one estate, the yield has been 50,000 piculs against 40,000 last year. Owing to the low quotations ruling for sugar, six guilders per picul even being offered for No. 16, cane growing has been relinquished on twelve estates in Java. The Colonial Bank has obtained leave to suspend payment for a month owing to the heavy fall of sugar in value. The Netherlands Indian Commercial Bank was on the eve of doing the same when timely assistance enabled it to tide over difficulties for the present.

TEA.—The *Produce Markets' Review* makes the following complaint :—"The quantity of Indian tea brought forward has not diminished, but the quality of the supplies has been decidely inferior to previous sales. A much larger proportion of common teas has been offered, and as these have to compete with cheap common China Congous, the Indian sorts have sold slowly at lower rates. Many of the teas brought forward this week have been almost devoid of the strength which has hitherto given Indian growths their superiority over those of China. This applies mainly to the lower qualities of whole and broken leaf, and the infusions of many of the former are at present singularly weak compared with those of teas previously offered."

SUGAR.—The prospects of sugar planters everywhere, and those in the West Indies in particular, are about as bad as they can be. The average yield of actual sugar from the beetroot in Germany is returned in Herr Light's annual review, recently published, as follows :—

1883-4	...	...	10·75 per cent.
1882-3	...	...	9·9 ,,
1881-2	...	...	9·9 ,,
1880-1	...	...	8·85 ,,
1879-80	...	...	8·55 ,,

The yield from the cane in Barbadoes, a material containing 18 to 20 per cent. of saccharine, is 6½ per cent. of sugar, so badly made that by the time it reaches England it is reduced by drainage to 6 per cent. of the weight of the cane. The beet growers thus get two-thirds more out of their raw material than Barbadian planters do, and against such a vastly increased yield, the very cheap production of the West Indies cannot hold its own, even if there were no bounties.—*Home and Colonial Mail*, Nov. 21st.

THE FLORA of northern Formosa is rich and abundant; the ground being plentifully covered, except in the neighbourhood of the sulphurous streams, with Indian lilics, roses, orchids, rhododendrons, tree-ferns, and a host of other unprofitably gay plants of tropical growth. The fauna, too, is extensive, and, with the exception of cobra-capellas and centipedes, possesses nothing that the French invaders need concern themselves about. But probably Admiral Courbet will prefer confining his operations to the immediate neighbourhood of the Keelung coal mines to advancing into the jungle retreats of these reptiles. He certainly will find quite enough to occupy him at the pits' mouths if he intends to work the coal. By the latest accounts we learn that the Chinese have fired the principal mine with kerosene oil, and have thus destroyed the entire plant of foreign machinery as well as burned out an immense quantity of coal. This mine has been worked under the superintendence of Mr. Tyzack, an English mining engineer, for the last ten years; and between 1874 and 1879 yielded the following very creditable results :—1874, 15,221 tons; 1875 27,665 tons; 1876, 31,593 tons; 1877, 28,948 tons; 1878, 25,788 tons; and 1879, 28,823 tons. If, turning from the burnt-out foreign mine, Admiral Courbet should direct his attention to the other pits, he will find them equally unavailable. Water, the enemy which next to fire is most dreaded by miners, has by long neglect been allowed to accumulate in the workings to such an extent that only after much tribulation would he be able to fill his bunkers from their seams.—*St James's Gazette.*

ACEEN.—The Batavia *Dagblad* of the 25th November states that M. Brau de St. Pol Lias, the wellknown enterprizing colonist, is expected in Java in April next, along with several associates, to apply for the sanction of the N. I. Government to a planting contract entered into by him and M. Errington de la Croix in 1881 with the chief and headman of Lohong in Acheen, where they intended at the time to open out a plantation, but were prevented by hostilities breaking out.

FREIGHT ON TEA.—We learn with some satisfaction that the Oudh and Rohilkhand Railway Company have, with a full appreciation of their own interests, lately reduced the freight for Indian teas over their line. This reduction, though somewhat tardily conceded, is none the less valuable. Hitherto the rates in force have been all in favour of the route from Saharunpur to Karachi, but the new tariff on the O. and B. Railway will now permit the planters of Kumon and Dehra Dun to export their tea from Calcutta upon as reasonable terms as from Karachi. The tea interest in these Provinces has lately been a good deal handicapped in competing with the other tea-exporting districts of India, and the reduction of freight now granted will doubtless be widely appreciated.—*Pioneer.*

SORGHUM SUGAR-MAKING APPARATUS.—Mr. C. Benson, M.R.A.C., Agricultural Reporter to the Government of Madras, recently submitted to the Director of Revenue Settlement and Agriculture, a copy of a letter received from the Blymyer Manufacturing Company, regarding their mills, &c., and calculated that "the cost of the set in New York would be about $146=£29-1-0, say R510." He added:—"If by the importation of such a set of machinery we can settle the question, whether Sorghum sugar can be profitably made in Southern India, the expenditure would not be large. The evaporator also would doubtless be very valuable in producing higher grades of sugar than the ordinary pans used in this Presidency." Mr. Wilson submitted the letter to Government, through the Board of Revenue, with the recommendation that a set of the apparatus be procured. The approximate cost in New York, he repeated, would be R510. The Government sanctioned the expenditure, observing that "the equivalent of £29-1-0 at the usual rate of exchange is not R510, but approximately R348. The cost of carriage to Madras has, it is presumed, been taken into account."—*Madras Mail.*

CINCHONA BARKING.—Says the correspondent to a Madras paper:—I referred last week to the discussion on cinchona barking, which is especially interesting to us all now. I think experience and the close observation of results is fast condemning the old system of shaving the trees. It is proved that the trees are severely injured, eventually, by the process which resembles slow starvation; that the bark, after its first renewal, rapidly deteriorates both in quantity and quality; and that the original plan of coppicing on an improved system will be found the most remunerative as well as an absolute necessary method of working in the future. The improvement is in allowing three or four stems or shoots to grow from each root, to coppice one or more of this at a regular interval, so that some portion of an estate may always be available for harvesting without the ultimate destruction of the trees. Already I hear of the evil results or the new plan of planting ledger clearings without the necessary support of "expense" playing—young coffee. An eminent proprietor actually wrote the other day to his manager complaining that "his three-year old ledger clearings were not yet giving any returns," and wanting "to know, you know," why he had to pay for their cultivation, and get none of his money back!! A curious fact, yet too impressed, I fancy, on many a sanguine but ignorant "absent proprietor."

CULTIVATION OF PATNA LAND.—The *South of India Observer* notices the discussion about the as-yet-untouched-patnas as follows:—If grass land has a good retentive subsoil there is no reason why tea, coffee, and cinchona should not thrive on it as well as on forest land, provided that proper manure is used, and the climate suitable. We have always been of opinion that in Ceylon the first principles of arboriculture were but little understood, though it must be admitted that the planters are a very enterprizing set of men. We may remark that the first coffee plantations in Wynaad were formed in grass land, and that land consisting of nothing but yellow, white, and pink, decomposed felspar, the result could easily have been foreseen. The small amount of available potash was soon exhausted, and the roots unable to extract the large amount locked up in the silicates, could obtain no food, so the plantations died out. Whereas the Kew estate on the same soil, and formed about the same time 1840, was giving excellent crops in 1862, when we saw it, because all the manure from the bazaar close by, and from the Club stables, was freely applied to it. We need scarcely mention many tea plantations on these hills formed on grass land, which have given fair returns and would give better, if potash were more freely applied.

ST. VINCENT, W. I:—GLOOMY OUTLOOK.—The leading proprietors of estates in St. Vincent have taken steps to reduce both the area of cultivation and the amount of their pay lists. As a rule, the overseers will be discharged, and the managers will be called on to accept an overseer's salary or leave. No canes will be planted for crop 1866, and the present acreage will be tilled and kept clean by jobbers and not by estate gangs. The coolie gangs must, of course, be kept up, but there are now very few indentured coolies on estates in St. Vincent. There is now no scarcity of labour; instead of that, many labourers will find difficulty in getting work on estates even at starvation wages. This, of course, will cause emigration to other places, such as Panama or the mines of Venezuela. Molasses are now almost worthless as a marketable commodity; and the only profitable way to utilize them is by giving them to the stock or turning them into rum. In two or three years (unless the price of sugar should rise to be remunerative) the cultivation of the sugar cane will be abandoned; and what in the meantime will be the state of the public finances? Where will the money come from to pay taxes to maintain the institutions of the colony? The outlook at present is very gloomy. Even at Guadelope, where large crops have been reaped, and where the finest *usines* in the West Indies exist, with the latest improvements that skill or capital could devise, ruin is staring planters in the face, unless they can get a bounty from the French Government to enable them to compete with the Continental beet producers.—*St. Vincent Witness.*

EUCALYPTS AT HOME AND ABROAD.—This was the subject of a lecture delivered in the committee-room at the International Forestry Exhibition just before its close by Dr. Howitz, of Copenhagen. Dr. Cleghorn presided, and briefly introduced the lecturer, who, after a few introductory remarks, said that his speciality in the science of forestry had been the cultivation of new forests. As he had a few years ago the opportunity of studying the eucalypts or gum trees of Australia, and had been subsequently engaged to report upon the introduction of those trees as forest trees into Algiers, Dr. Cleghorn had requested him to give a short lecture on the subject. The jarrawood *(Eucalypt marginata)*, would supersede all others for piles for wharves and a certain class of shipbuilding; while the red gum *(Eucalypt rostrata)* and its congeners wood be placed foremost as railway sleepers, wood pavements, &c. Where hardness, durability, and resistance to the attacks of insects were required, these trees were preferable, and it was certain that they had a great future before them. He believed that the large quantities of our native trees, which had hitherto been used for such purposes, would be forced into other branches of industry if the use of the eucalypts became general. The cultivation of gum trees in South Africa and the countries round the Mediterranean Sea would bring the products within reasonable distance of the markets of this country, and lessen their cost considerably. Dr. Howitz explained at some length the hygienic properties of the eucalypts, and mentioned, as showing the astonishing influence they possessed, that the village of Ain Mokra, near Bona, Algeria, owed its fame as a healthy spot to the presence of the eucalypts.—*Colonies and India.*

QUININE.—It is announced that C.F. Boehringer & Soehne, the quinine manufacturers, of Mannheim, Germany, have established a branch house in this city, with Mr. L. Engelhorn, a brother of one of the members of the firm, in charge. Mr. A. Boehringer has been here for some time to establish the branch house which has become necessary by reason of the increasing demand for the products of this house, which have a high reputation here.—*N. York Independent Journal.*

AUSTRALIAN TIMBER.—From a report of the Board appointed to inquire into and experiment on the best kind of timber grown in the Australian colonies, and adapted for the construction of railway vehicles, it appears that the woods which the Commissioners mention as among those suitable, are blackwood, mountain ash, bluegum, and Gippsland mahogany. Under test the blackwood presented results which were superior to any other timber. The mountain ash was second to the blackwood for railway purposes. It should be felled, the Commissioners think, during the winter months, when it has attained maturity, and is between four and five feet in diameter, and it might remain felled for six months before being broken down into planks for seasoning. Bluegum should be treated in the same manner. Going somewhat beyond its reference, the Board deals with the question of timber licenses, and recommends that getters be compelled to pay for the timber felled, and to confine their operations to a given area, or otherwise that selected lots of trees be sold by tender. It is also strongly recommended that a forest board should be called into existence.—*Wool and Textile Fabrics.*

THE LI-CHI FRUIT.—This very typical Chinese fruit, which has attained a certain amount of popularity in England, possesses an interest far exceeding its virtues as a pleasant luxury. Its history dates from 140 B.C., when the Emperor Wati endeavoured to introduce it from Annam, its native habitat, into his garden at Chang-an. Hundreds of plants were brought to China for many successive years, but they all failed to acclimatise, and it was found useless to make any further efforts. This fact, however, only increased the value of li-chi, which in 200 B.C. was sent as a tribute from Annam to the Emperor Kao-tsu at a frightful cost of human life. As the fruit only keeps fresh for ten days at the most, and it was necessary that it reached Chang-an in good condition, relays of men were required to run at full speed, bearing a load of li-chi, and in this forced travel the majority of them broke down through sunstroke by day and the attacks of serpents and wild beasts by night. In the middle of the eighth century, the Princess Wang, whose appetite for li-chi was unappeasable, established a pony express, and although this also was carried out at a great sacrifice of horseflesh, the end justified the means, as, smitten by her great beauty, the Emperor Husan Tsung made her chief lady of his harem, notwithstanding that she was already his son's wife. This little family difficulty was soon arranged, and an exchange was made of another beauty out of the seraglio, with whom the son was quite satisfied. The Princess Wang was not peculiar in her liking for li-chi, for although the medical men of the time considered them as heating, persons have been known to eat a thousand a day. The poet Su Tung-po, who was in exile at Canton, allowed himself the moderate quantity of 300 per diem, and wrote a poem in their favour, declaring that they were delicious enough to reconcile a man to eternal banishment; moreover, it is stated in the Genii Records that there were individuals who, from having attained immortality by using its flowers and fruits, were called li-chi genii. Ko-Hung, a great authority among the Taoist philosophers, praised it unceasingly as a "marrow tonic," but, notwithstanding his constant use of it, he died at eighty-one under some uncertainty as to whether he had become a li-chi genius or not. Perhaps some of these attributes may be accounted for by the fact that the li-chi tree does not come to maturity until it is fifty years old, but, once begun, it will continue to bear fruit for 500 years, while its timber keeps sufficiently sound for use for nearly a thousand years. With such virtues, one ought scarcely to speak of its minor good qualities, which are of value in hastening small-pox pestules, and as a tropical application for boils, swellings, and toothache. It is singular in its habit of growth, being found in China growing on the hills in Kwangsi and in the plains in Kwang-tung, but in all cases at a distance from water. For the first five years, according to Dr. M'Gowan in the *North China Herald*, it requires to be protected from cold, being remarkably sensitive to frost and electricity, which is very prejudicial to it, so much so that a thunderstorm will cause the flowers and fruit to be small. It is singular that when the fruit is cut it should be at once taken from the tree, otherwise the birds and bats will make a clean sweep of it, although they will not touch it as long as it remains upon the tree uncut.—*Public Opinion.*

FENCE POSTS THAT WILL LAST.—A writer in an exchange says:—"I discovered many years ago that wood could be made to last longer than iron in the ground, but thought the process so simple that it would not be well to make a stir about it. I would as soon have poplar, basswood or ash as any other kind of timber for fence posts. I have taken out basswood posts after having been set seven years that were as sound when taken out as when first put in the ground. Time and weather seemed to have no effect on them. The posts can be prepared for less than two cents a piece. This is the recipe:—Take boiled linseed oil and stir in pulverized coal to the consistency of paint. Put a coat of this over the timber, and there is not a man that will live to see it rot."—*Florida Dispatch.*

THE SHAPE OF ORANGE TREES.—"Just as the twig is bent, the tree's inclined." You can give your trees almost any shape or form by a judicious pinching of the soft, delicate young shoots. Do not let these get large enough for the knife or clipping-shears; but if they are inclined to grow off weak, long and straggling, pinch them into proper shape with the thumb and finger nails. Tie the drooping recumbent shoots upright to the main stem of the tree, or to a stake set for the purpose, and nip the end off to give them a "stocky" growth. Do not allow more than a single stem or trunk to grow up from the ground; let the branches come out low, and endeavour to give your tree the form of an obtuse cone, or blunt pyramid. Go among your trees often, and observe them carefully. All irregularities of growth may readily be corrected, if taken in time, and the wonderful *vitality* of the orange tree makes it an excellent subject for correction an experiment.—EDS. *Florida Dispatch.*

A GREAT FOOD STAPLE.—The last *Gazette* contains a very interesting report by Mr. Benett, the Director of Agriculture, on the wheat production of these Provinces. It brings the whole information available up to date, and sketches with some pretence to accuracy the future of the wheat trade. On an average of the past five years we learn that in the N.-W. Provinces there are 1,859,755 acres of irrigated and 1,724,419 acres of unirrigated land under wheat; in Oudh there are 962,817 acres irrigated and 364,301 unirrigated, making up the imposing total of nearly five millions of acres under the cultivation of a food staple which, though largely consumed in the place of production, is available also in large quantities for export. The question naturally arises—how much of the produce of this area is available for export, and what are the chances of Indian wheat in competition with the outturn from the almost inexhaustible stores of North America? Mr. Benett calculates that the average outturn per acre may be taken as 22 bushels on irrigated and 12 bushels on dry land. An estimate framed by the Government of India has put the average produce at 13 bushels only, a little more than is estimated as the average produce in America; but this estimate can only have been obtained by supposing that half the area under wheat is grown on inferior land, which is, as Mr. Benett justly points out, far from being the case. Wheat is always sown on the best land in the village, where there has been no previous crop (except in some cases indigo), and is almost invariably manured where irrigation is available. Moreover, it is much more carefully cultivated than other food crops, and is indeed, as pointed out by Mr. Wright in the Revenue Administration Report for last year, next to sugarcane the mainstay of the intelligent Jat cultivators, who make the Meerut Division a rival to the Province of Oudh as the granary of India. In the Meerut district as much as 52 per cent of the *rabi area* is under pure wheat, of which 60 per cent is irrigated. That the cultivation of wheat is steadily increasing is beyond doubt, and there is no reason to believe that the limit of increase has been reached. Nor is there any need to fear, as some alarmists would have us that wheat is being cultivated to the exclusion of other food staples. . . . We can only say that we cordially agree with Mr. Benett's recommendations as to the opening up of good metalled feeder roads to the principal stations where wheat takes the rail. There can be little doubt, he says, that the present market price of wheat is materially increased by the cost of dragging it along miles of sandy unbridged roads, and it is not unlikely that the cost of carriage by road keeps many tracts out of the market altogether.—*Pioneer.*

A NEW INDUSTRY has just been started in East Kent—that of growing crops of lavender and peppermint for the purpose of extracting the oil and supplying it wholesale. A large breadth of land at Grove, near Canterbury, was planted with lavender and peppermint by way of experiment, and the result proved in every way satisfactory. It has, therefore, been determined to establish extensive works on the spot (which is in close proximity to the South-Eastern Railway) in order to carry on the process of extracting the oil from these plants, neither of which, it is stated, has ever been cultivated before in Kent.—*European Mail.*

THE RUBBER INDUSTRY OF THE UNITED STATES.—The rubber industry of the States has no rival in foreign countries. There is something like $75,000,000 invested in the business of manufacturing rubber goods, $30,000,000 of which is confined to the rubber boot and shoe industry. The total number of employés is placed at 15,000, and the total number of factories at one hundred and twenty. According to a recent census bulletin the value of the annual product is $250,000,000. Some 30,000 tons of raw rubber are imported every year, which, when combined with other materials in manufacturing, amount to 300,000 tons. The market price of the raw material has been forced up to $1·25 per lb., while six years ago the price was scarcely fifty cents. In consequence of the advance in price, several substances have been prepared as substitutes for it, of which celluloid is the most important.—*Industrial South.*

INSECTS AND HOT WATER.—Speaking of the destruction of insects on plants, a writer in an English publication gives his experience of a novel remedy, and one that to the inexperienced would perhaps appear quite as fatal as are the various insects. He advises the application of hot water. He says:—"Hot water at a temperature of about 120° I find the most effective remedy I have ever tried for destroying insects on plants in the green-house. The plants may be either immersed in it, or the hot water may be applied with a plant-syringe, which is the more convenient of the two modes of applying it. If applied with a plant-syringe the water may be a few, say 10° hotter. While death to insects, the hot water seems not to injure the plants in the least. I find one drenching of hot water with a plant-syringe has been sufficient to rid plants of red spider, where time after time cold water drenchings had been in vain."—*Planter and Farmer.*

THE WIRE WORM.—This insect is about the thickness of a pin, with a stiffish, yellow-brown, shiny appearance. He may be found almost anywhere in gardens, to which he is a determined enemy. He devours all kinds of agricultural produce, roots, grain, and fodder crops all coming alike to him. The click beetle is his father or mother, or both; and *Knowledge* describes the skipjack or click beetle thus:—Skipjacks are narrow, elongated insects, with short legs and hard integuments. The head is small and often much sunk into the thorax, and carries a pair of long, distinctly jointed antennæ; the thorax is of a large size, and roughly speaking, more or less quadrangular in outline, and convex above and beneath. The elytra or wingcases cover the body, and conceal a pair of ample membranous wings. Each is somewhat triangular in shape, and they form when closed a strongly-arched, shield-shaped surface; they are usually marked longitudinally with parallel grooves or furrows, and covered more or less densely with short hairs. The under surface also is strongly convex, and the legs are short, and capable, like the antennæ, of being folded close up to the body. When surprised or alarmed it will thus feign death, relaxing its hold of what it may have been clinging to, and falling to the ground as often as not, on its back. There are about 60 species of skipjacks, some of which are very common. Wire worms are the larvæ of these insects. Fortunately they have a good many natural enemies. A variety of artificial remedies has been proposed. To apply liquid manure freely. This first of all strengthens the plant and has the effect of driving away or killing the enemy; paring off a thin coating of the soil, which will contain most of the insects, and then burning it; imbedding in the soil at short distances apart slices of carrot and turnip to serve as traps. By the latter method as many as 150 wire worms have been entrapped close to a single hop-hill. In this case as in many others insect-pests are the outcome of careless or bad management.—*Ibid.*

INSECTICIDE.—What is known as the kerosene emulsion is one of the cheapest and most easily applied insecticides that can be used. It is made by adding one quart of kerosene to five quarts of skim milk in a close vessel, and shaking till the two unite, after which it can be diluted with water to five or six times its bulk, applied to vegetation with a sprinkler, or force-pump sprayer. It is effectual against the entire class of insects which feed upon vegetation.—*Indian Agriculturist.* [Yes, but unfortunately even if sufficient skim milk could be obtained, there is the difficulty and expense of application over large surfaces. It seems likely enough, however, that much good might be done by means of pumping machinery dashing jets of ordinary water on patches of plants known to be affected by insecticides.—ED.]

FERTILISERS: WOOD ASHES.—Now that the question of fertilisers is coming more and more to the front, the following hint will be of value to every farmer and selector, for all have more or less wood ashes at their disposal. According to a recent authority, the best results are obtained from ashes by the admixture of a small proportion of salt. As is well known, wood ashes contain nearly all the mineral elements necessary for plant life. There is one exception to this—burning causes the chlorine to be carried off in the smoke; this is readily supplied by the application of chloride of sodium, or common salt. Hence a sprinkling of salt on a heap of ashes will very materially enhance its value. Besides and beyond this, it should always be remembered that the application of salt to land has two specific advantages: it keeps the soil moist, and it destroys insect life—two most valuable properties in this climate. —*Planter and Farmer.*

THE VALUABLE MEDICINAL properties of the *Eucalyptus globulus* or blue gum of Australia are, we are glad to find, becoming more and more recognised every year. The latest use to which the product of the tree has been put is in the manufacture of soap, and, according to the *Rangoon Gazette*, Mr. Hugh Fraser, a native of Aberdeen, has established a factory at Poozondoung for the manufacture of a soap which will impart disinfecting properties, as well as thorough cleanliness, to all linen and to the skin. It had been ascertained beyond a doubt from extensive wooden hospitals and other buildings constructed from the wood of the Eucalyptus that highly satisfactory results, and an influence beneficial as a preservative and preventative against fever, cholera, and smallpox, from the strong, pungent, but most agreeable and pleasant odour, had been the outcome, and this fact led Mr. Fraser to utilise the product of the blue gum in the manufacture of soap. If the "Eucalyptal Soap" is a success in India, surely there is an opening for some enterprising Australian to start the manufacture of a similar article in the colonies.—*European Mail.*

ROSELLAS.—By an advertisement in this issue it will be seen that a firm of Brisbane jam makers, Messrs. McLeod & Co., are proposing to enter into contracts with growers for the purchase of any quantity of rosellas. We are exceedingly glad to be able to make this announcement. Rosella jam is purely and distinctively a Queensland production, the *hibiscus sorbifolia* growing in no other part of Australia, nor so far as we know, in any other country occupied by a European race. It is, too, one of the best, if not the best, of all the local products as a jam, having a flavour and piquancy of its own, superior to any other jam. It is, therefore, highly desirable that this much-prized delicacy should become widely known; it is then certain to be very much sought after. As the roscella becomes more widely known, its cultivation cannot fail to be a source of wealth to the East Moreton gardeners and farmers. Unlike all other fruits—if indeed the rosella may be characterised as such—this is an annual and can be raised in consequence with great expedition. There is no reason why the poorest farmer should not grow an acre or two of rosellas this coming season. One strong point about this crop is, that it does not require particularly rich soil. Given deep cultivation and liberal manuring around each plant, with stockyard manure, and the poor clay soils around Brisbane will produce the very best crops of rosellas. —*Planter and Farmer.* [The rosella grows freely in Ceylon and could be turned to account if there arose any appreciable demand for the preseve, which can be made from it.—ED.]

THE TONGA PLANT.—Of this celebrated plant Mr. Wm. Bull says:—"A remarkable Arad introduced from the South Sea Islands; it has large shining dark green elliptic-oblong pinnatisect leaves, more or less oblique, and having numerous pellucid spots scattered along the region of the midrib. When the plants are small and young, the leaves are entire, but gradually develop, until they finally become pinnatisect. The large inflorescence resembles that of Monstera deliciosa. From this bold and ornamental stove Arad, a very valuable and important drug is prepared, known as 'Tonga, the specific for neuralgia.'"—*Gardeners' Monthly.*

RULES IN PRUNING.—In a prize essay on the philosophy of pruning, J. F. Wilhite, Boone county, Mo., gives the following rules in pruning:—1st—Always leave an inch of wood beyond their terminal bud, and let the cut be on the opposite side from the bud. 2nd—Always cut upward and in a sloping direction. 3rd—Prune so as to make but few wounds, and cut the surface as smooth as possible. 4th—In cutting out an old branch prune even to the stem, that the wounds may heal over quickly. 5th—Prune so as to obtain the quantity of fruit desired from the smallest number of shoots.—*Florida Dispatch.*

THE USE OF HOT WATER to destroy insects appears to be quite as effectual for the destruction of subterranean enemies as those on the foliage. At the last meeting of the Indiana Horticultural Society, in December, an extensive amateur fruit grower spoke of having used hot water—pouring a quart about the root of each tree—for the borer, which of course was done in early spring while the trees were yet dormant. In this manner he went over his young peach orchard of several thousand trees; and while the trees had previously suffered badly from the borer, he never saw signs of them afterward.—*Planter and Farmer.*

CRANBERRIES.—Wisconsin is the leading cranberry State. Michigan is the second. The average yield of a marsh is 150 to 200 bushels to the acre. The picking season lasts two weeks, and three bushels is a good day's work. Seventy-five cents per bushel is the picker's pay. The Wisconsin crop is nearly all shipped to Chicago commission houses, at $2 75 to $3 per bushel. A well-managed marsh containing 400 acres of vines will yield about $50,000, and with a very large crop the sum can be nearly doubled. The entire crop of the United States is consumed at home. Englishmen don't take kindly to the fruit, and a ship load sent to London a few years ago could be sold for the cost of carrying.—*American Grocer.*

EXTRACTS OF TEA AND COFFEE AS SUBSTITUTES FOR COCA AND GUARANA.—Dr. Squibb, in the *Ephemeris*, quoted by the *Detroit Lancet*, gives in detail the reasons why he has sought to bring to the notice of the profession the extracts of tea and coffee as substitutes for the extracts of coca and guarana. Briefly, he found by observation and experiment, that there was but little of good coca and guarana to be found in the market. The price asked for the poor article was very large. As a result, the profession has been asking the people to buy poor inefficient drugs at a high price. The results have been very unsatisfactory, both to scientific physicians and to patients. To obtain a real substitute for these drugs, Dr. Squibb has taken the trouble to make careful physiological tests. All of these drugs contain caffeine, or an alkaloid having an analogous action. Apparently most of their virtues depend upon this alkaloid. Hence he took as a standard a dose of caffeine which would always, under definite conditions, produce a given effect. Then he took such doses of each drug as were needed to produce the same effect as the standard doses of caffeine. In this manner, he has ascertained that three grains of caffeine are equivalent to 180 grains of coca, to 70 grains of tea, to 60 grains of guarana, to 150 grains of coffee. The details given as to the process by which the extracts of tea and coffee are made is such as to gain the confidence of all who investigate it. The differences between the effects of caffeine and the extracts of green coffee, tea, coca, or guarana, are difficult to describe. In general terms, it may be said that each of these is caffeine and something more. The effect seemed broader, more comprehensive, more agreeable, and giving a better sense of rest and well-being. We shall await with interest the result of a wider clinical experience in the use of these agents.—*British Medical Journal.*

LIQUID MANURE.—Labor is too dear in this country to profitably use liquid manures. If the soil is kept well fertilized, frequent cultivation will supply crops with moisture more cheaply than it can be drawn on the land and distributed.—*Southern Planter.*

MEALY BUG.—A paint made of gas tar and clay, used with a brush over the stems of grape vines before the leaves push out, is found by hothouse grape-growers in England a sure remedy against mealy bug.—*Gardeners' Monthly.*

RICE IN QUEENSLAND.—A Chinaman living near Cairns has harvested a crop of excellent rice, of which he ha about a ton and-a-half per acre. At the present rulins prices that will pay handsomely.—*Planter and Farmer.* g

A LINSEED FACTORY has just been started in Canterbury, New Zealand, with a capital of £3,800. It is proposed to make oil, cake, and rope and twine. The object is to encourage the growth of other crops than wheat, which threatens to become too cheap to pay.—*Ibid.*

EXTENT OF LAND IN FRUIT.—Few people have any idea of the enormous extent of land under fruit culture in the United States. A correspondent from Barnesville, Ohio, tells us that about 6,000 bushels of Raspberries were sent from that station last season, and, as we suppose, seventy-five bushels to the acre would be a good crop, this gives about eighty acres. It seems almost incredible, but suppose it must be so.—*Gardeners' Monthly.*

SOIL ANALYSIS.—Not so much is said now as formerly about the advantage of analyzing soil to learn what fertilizers are needed. It is a very uncertain and unpractical method of finding soil deficiencies. If crops are poor in favorable seasons it is evident that some element of plant food is deficient. The lack is more likely to be phosphoric acid than anything else. Try that. Then if it does not produce the desired result, add nitrogen and potash. These will invariably bring a crop if applied in large enough quantity, however barren the soil.—*Southern Planter.*

THE HYDRANGEA AS A TEA PLANT.—The *Gardeners' Chronicle* says that a Japanese shrub, Hydrangea Thunbergia of Siebold, and called by the Japanese Amatsji, or "Tea of Heaven," is found on the mountains of Aiva and Souaki, where the leaves, which are oblong and serrate, are, when dried, used by the natives as tea, under the name referred to above, and by the Chinese as "Di-sido-san." It is sometimes known as "Sweet Tea" by the Japanese, who assert that there is a variety of the same plant with bitter leaves, which they call "Kakassoo."—*Gardeners' Monthly.*

FIBRES.—In the course of a comprehensive treatise on "Fibre Culture in Southern India," Mr. W. J. Kemp draws particular attention to the collection of the crop, which may be regarded as the most important item in the whole system of fibre culture. Mr. Kemp writes:—"This is a subject requiring unremitting attention in order to secure, as near as possible, a uniform bulk of fibre suitable for marketable purposes; the stems suitable for harvesting must be carefully picked out and selected from amongst the green and partially developed ones, and, although it is a difficult matter to draw a hard-and-fast line as to when the stems are ripe enough to be cut, it may be taken for granted that the most suitable time is when the full-grown stems commence to appear yellow from the base upwards, thus denoting a ripened appearance approaching maturity which will be found the best time to harvest the stems. Well-grown stems of rhea should have but few or no lateral shoots, as should lateral shoots prevail they can only be considered as signs of slow growth and inferiority as regards quality of fibre. The stems should be cut as closely as possible to the crown of the plant, and after being carefully trimmed of any shoots or limbs, should be tied in conveniently-sized bundles in readiness to be carried to the fibre cleaning machine, and for the purpose of carrying, young boys or women will prove the most economical. Should the estate, however, be of large extent, and well roaded, small pack-bullocks would be found useful for purposes of carriage on account of the greater number of bundles they could transport to the machine at the same time. In order to prevent as much as possible the after expense of sorting and sizing the various lengths of fibre, it will be found very desirable that the stems should be tied in bundles according to their different lengths at the time they are gathered, and decorticated accordingly."—*Indian Agriculturist.*

THE SOUAJNA: OIL OF BEN.

TO THE EDITOR OF THE INDIAN AGRICULTURIST.

SIR,—Referring to "C. S. F.'s" letter in your issue of the 6th idem, the *Souajna Oil*, if it is from the Anglo-Indian horse-radish, procured by expression from the ripe seeds, is a very superior hair oil, when boiled, dyed, and scented, and far more efficacious than all the Macassar, and other hair oils, and douches, that I have ever employed. Especially is this the case in diseases of the hair, and baldness, after fevers and other eruptive diseases, when the hair falls off in tufts.

The juice of the roots possesses the pungent taste and smell of the horse-radish of Europe. It is added to mustard for the table, and to sinapism (mustard poultices) to render its action, as a rubefacient and vesicaut, energetic in acute affections.

Decoction of the root is very serviceable as a gargle in sorethroat and hoarseuess. The pods, tender leaves, and flowers are esculent vegetables for curries (*chickee bajee* of the natives). The soft reddish gummy exudation is employed as a sweetmeat boiled in syrup or honey. Blocks of its wood are converted into floats to teach boys to swim, and two large blocks excavated and lashed together are used as "fishing boats." The oil, if denuded of its stearine, is very useful for protecting guns, swords, instruments, watches, &c., from rust. I have used it for all the above purposes most successfully for nearly half-a-century. I consider it a most valuable tree, and I have dozeus of it in the garden always.

P. O.

[The *morenga* plant is referred to. We saw it growing so far in Northern India as Allahabad, but were told that the pods were never used as food. We never before heard of the use to which the wood is said to be put.—ED.]

THE FORESTRY EXHIBITION AT EDINBURGH: INDIA.

The Indian exhibits form a splendid collection of forest products; indeed, this department is the largest and the most valuable in the Exhibition. It occupies the whole of the middle transept, and is under the superintendence of Colonel Michael, who, as Lieutenant Michael, was appointed the first forestry conservator in Madras thirty-six years ago. Though systematic forestry in India is of so recent origin, it has already made great progress. The Forestry Conservancy is now a great department of State, and the reserved forests cover 40,000 square miles. An important part of the work of the department is the survey of the Indian forests, which is being rapidly pushed forward. The result is shown in a series of upwards of 100 excellent maps, partly exhibited on the walls and partly shown in portfolios. In the official catalogue the Indian collection has had greater justice done to it than any other. It is treated with exceptional fulness and particularity, as is indicated by the fact that "India" has had nearly one-half of the catalogue given up to it. Sir George Birdwood contributes to this division a preface containing an interesting account of the origin and progress of forestry in India. From the Forest Department of Assam there come specimens of india-rubber collected from creepers growing in the forests of the district, and also specimens of tools used by the foresters. From the Government of India there comes the "Index Collection" of timbers and forest products. Besides upwards of 100 specimens of gums, resins, dyes, tans, fibres, oils, seeds, perfumery, and medicinal products, it presents nearly 500 examples of different kinds of wood grown from the Himalayas to Cape Comorin. From the Coimbatore district there come 138 specimens of various woods and wood products. There are also extensive collections sent from the North-West Provinces, from Malabar, from Rangoon (including specimens of teak, both in sections and in planks), from the Punjab, from Travancore, from Bombay, from Madras, and from the Andaman and Nicobar islands. There are no finer specimens of polished wood in the Exhibition than these of padowk and poore from the islands last named. In the Indian Court there are valuable contributions to the literature of forestry, in the shape of reviews and reports bearing on the forest administration in the several provinces. From India's jewelled pendant, Ceylon, there come specimens of woods, barks, fibres, gums, and vegetable oils. There are also complete collections of the products of the coconut and the palmyra palm, and of cinchona barks, with specimens of the flowers of the tree. This is, perhaps, the most convenient place to notice the remarkably fine collection of forest produce sent by the Maharaja of Johore, in the Malay peninsula. It comprises specimens of timber prepared at the Johore sawmills, which are superintended by a brother of the Maharaja. There are samples of 350 different kinds of wood produced in the State, chiefly varieties of cedar. As Johore produced the first guttapercha known to commerce, it is natural to find specimens of it in the collection. There are also specimens of caoutchouc, gum, and camphor; and besides models of timber-rafts, there is a complete set of Malay forestry tools and implements.—*European Mail.*

CULTIVATION OF CIGAR TOBACCO.

WHAT THE CIGAR TRADE WANTS.

The trade demands, at the present time, a fine silky leaf, of good fragrance and of good burniug quality, and the grower who proceeds counter to the demands of the trade will have to accept of low and unremunerative prices at harvest. The day has gone by when tobacco of the Irishman's lot, who, in describing it, said that "the leaves were as big as a barn door and as thick as his coat," will sell.

DIFFERENT VARIETIES OF TOBACCO CONTRASTED.

In contrast with the above described lot, look at the Sumatra leaf. I have seen bales of it carrying nearly 150 leaves to the pound, while twenty and twenty-five leaves of thick seed leaf, and sometimes even less, will weigh a pound. The pound of Sumatra is worth $1·50 to $1·90, while this large Connecticut leaf is worth only about ten to fourteen cents per pound. Our growers now have a variety known aa Havana Seed, of which I have tied up hands taking 108 leaves to weigh a pound. Ordinarily, sixty leaves will weigh a pound. Now, suppose we take fifty leaves as an average. Fifty leaves will make 100 first wrappers, and fully an equal number of second wrappers. Thus one pound wraps 200 cigars; or five pounds to the thousand, and when used the veins are very small, and the cigar is beautiful, commandiug a higher price than the coarse ones usually made from heavy wrappers. The fine ones sell readily, white the others are disposed of only at low figures.

TO PRODUCE FINE, DESIRABLE LEAF.

Again, we find fiue tobacco selling readily and at remunerative prices, while the other is a drug on our hands. To produce fine, desirable leaf, we should fit our land well, supplying such plant food as will produce the quality of leaf desired and to have it in abundance at the proper time. A sufficient number of plants should be set to the acre, so that a great overgrown leaf may be avoided. I think somewhere about 6,500 to 7,000 plants to the acre is the most desirable number. Constant attention in the growing season should be given to the crop, so as to induce a rapid growth, that there may be abundant time for ripening properly. It is all idle for growers to say that these attentions are of small avail in getting what is desirable. It isn't all luck in producing a good crop. There is a necessity for an intelligent manipulation of the crops for us to produce what we most desire.

Frequent hoeing is of great advantage. It keeps the crust broken, lets heat and light and moisture into the ground, and thus hastens the growth. Hoeing oftentimes disturbs the cut worm. I do not think that so much time should be expended on the hoeing as was the case in olden times. Some growers would pull away all the earth from the plants, often disturbing the roots in so doing, finally pulling up clean fresh earth about the plants, I prefer to leave the plant wholly undisturbed if possible. I have seen a man work all day on a third of an acre, while another grower would do an acre in the same time. I prefer to spend the time in hoeing it over again, and think better results will follow such a course.

THE BEST TIME FOR TOPPING.

The question of the best time for topping tobacco is settled by different growers according to their own preconceived opinions. Much depends on the fertility of the soil, the amount of manure in the soil to throw out the upper

leaves and fully develop the lower ones. If the land is in high condition and the season is propitious, I prefer to let the blossoms show pretty well before topping. The upper leaves are apt to leave a whiter ash, and attain a larger size. Again, the grower can usually top a larger portion at the time he goes through the field the first time. The true Havana seed is liable to blow over, producing crooked, uncouth looking plants, and this is a strong objection to letting it stand long after the seedbuds make their appearance. The weather, too, has something to do with it, if very dry. I don't care to exhaust any of the resources of the plant and hence top earlier. It will be seen there are many circumstances which come in to modify any and all rules.—*Farmer's Home Journal.*

MADRAS TEAK.

The *Rangoon Gazette* does not see why the trade in Teak timber with Madras should not expand, as that with Bombay and Bengal. It apparently seems to overlook the fact that Madras has her Nellumbore Plantations, her Teak Forests on the Anamullais and in Wynaad. The *Gazette* also complains that the Madras demand for teak has only gone up from seven-and-a-half to twelve lakhs. We are only surprised to find that with our large depôts of teak to draw from, that the Burmah supply should have risen from seven to twelve lakhs. There must be something rotten in the management of our teak supply to allow Burmah, not only to send this amount to Madras, but to charge about three times as much for teak in Madras as it is sold for at the Madras Forest Depôts. For instance, a great deal of teak is sold in Wynaad for some 12 annas the cubic foot; the same would realise in Madras at least 2 rupees, which would leave a handsome profit for Government and at the same time undersell all Burmah teak. We find by the *Gazette*, that the price of teak in Burmah rose from 48 rupees the ton in 1879-80 to 95 in 1883-84. This is nearly 2 rupees a cubic foot in Rangoon; and to meet all risks and a profit, this Teak commands from 150 to 200 rupees a ton in Madras. In his work on *Forestry in Southern India*, General Morgan has shown that teak can be delivered from the various Government Forests, in Madras for 75 rupees the ton, thus leaving a handsome profit to Government, if sold in Madras for 125 rupees a ton. Against this price Burmah teak could not compete. Madras last year took 14,000 tons of Burmah teak: the greater part of this could have been supplied from Madras Forests. Nellumbore alone could supply five thousand tons annually, and why it does not, is one of those inscrutable things that no one can fathom. The 1884-85-86 Plantations are quite fit for felling, as the timber in them averages 40 years, and one hundred acres contain something like ten thousand tons. Assuming only half of this amount is cut out annually and we have the 5,000 tons for Madras, and so far from this amount having any effect upon the annual outturn, we believe, in a few years it may be doubled, as the planting is over 2,500 acres, and every year a new lot attains an age of forty years, this being the age when it is timber To pour 5,000 tons into the Madras market would at once raise the Forest Revenues by about six lakhs of Rupees. Then again from Wynaad and the Anamullais some two thousand tons could be sent to Madras at the same amount of profit, or the sale of teak alone from these forests would equal the whole of the present Forest Revenue.—*South of India Observer.*

MANGO CULTIVATION

is thus described in the Report on the Gennesh Khind Botanical Gardens, Poonah:—

Mango Trees.—4,300 grafted trees have been produced this season. The number was limited by the quantity of suitable pots procurable. As the demand for grafted mango trees is very high, I have laid in a stock of pots that will permit a much larger number to be prepared next season. The price of the trees is ans. 8 each, packing securely to travel fifteen days costs Re. 1 per doz., and rail carriage by goods train may be calculated at Re. 1 per doz. per 100 miles. The varieties of mango grafted are chiefly Alphonse and Pirie. It is well known that those varieties are more delicate than seedlings, and I find an impression prevails that grafting is the cause of the weakness. From my knowledge of plants, I am unable to take that view of the subject. A badly-executed graft will no doubt form an impediment to the flow of the sap, but if the tree survives, it must get over that impediment in a few years, and in a well-made graft the union becomes perfect in a few months. The delicacy of the varieties beforenamed is more probably due to constitutional weakness, and there are several seedling trees throughout the country, the fruit of which I am assured is sold under the name Alphonse. It is probable that among those trees some of good constitution may be found, which although not quite equal in flavour to the real Alphonse may be valuable for hardiness and other good qualities, and by skilfully grafting those trees, we can have large groves of grafted mango trees thriving with as little care and attention as the groves of seedlings may be seen at present, if suitable soils and situations are selected. I append a few notes on the soil and climate of Sivapore, which has at least 5,000 mango trees as an instance of suitable conditions.

Mango Enemies.—The grafting work was interrupted this season by a horde of bandycoots that invaded part of the garden and destroyed over two hundred of the best stocks, young seedlings, by eating them through near the surface of the ground. It appeared that the pith in the centre of the stem was the part sought after. The destruction was begun suddenly on the plants being taken to the proper place for grafting, and next morning about 100 were found destroyed. Phosphorous paste was the only poison at hand, and it did not prevent an equal amount of mischief from being done the next night, but arsenic mixed up with bread crumb and fat was thoroughly effectual, and we had no further trouble from that source.

Soil and situation fit for Mango growing.—The mango grove at Sivapore with at least 5,000 trees is a good example of a suitable soil and climate for mango and fig growing, and as I have recently examined the grove carefully, I may give my notes here.

The soil from the surface downwards, as may be seen in many places exposed by water currents and in unfinished wells, is—

1*st.*—Dark brown or black loam, about ...	5	feet.
2*nd.*—Calcareous marl, about	9	,,
3*rd.*—Coarse gravel, about	2	,,
4*th.*—Very porous nodular trap, about ...	3	,,
5*th.*—Rock in an extremely disintegrated condition, not sand, but resembling what one would imagine would be the effect if lava had flowed into water and been cooled suddenly, at least	4	,,

Water is found abundantly in the last-named strata. The slopes are gentle, permitting the rain to percolate freely. Laterite outcrops occur in the neighbourhood, and the site is sheltered by hills on all sides except the south-east. Thanks are due to Rao Saheb B. R. Natu of Poona for permitting his famous mango tree at Kadus called Khunt to be grafted. I expect to remove 80 grafted plants at least from that tree in a few days. To that gentleman I am also indebted for an opportunity of successfully performing a grafting operation that has very seldom been done in this country. A branch was brought by a cartman from the Khunt mango at Kaduz, 40 miles away, and grafted to a six-months old seedling here. The graft made is what is known as the saddle. Grafting branches on to old trees in the ground is common, but the operation described is adapted for plants to be distributed.

I fear that the delicacy of the operation will prevent it from being much employed.—*Indian Agriculturist.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, September 29.

Dr. Köning, of Münster, has made known the results of his analysis of beet pulp, derived from the diffusion process, in a fresh and in a dry state. He operated on 2½ tons of the fresh pulp, from which he obtained 6 cwt. of dried stuff. The practical results corroborate those obtained by Maercker, namely, that it is more advantageous to employ the pulp in the desiccated state, then when preserved in silos in the fresh condition, and the loss consequent on the acidulous fermentation.

In 1858 M. de Troguindy purchased at Plouaret, in the north of France, a property of 500 acres. It was a valley half marsh, half underwood; he drained and reclaimed, tried several systems of culture, till at last he "struck ile." He resolved to cultivate only green crops and fat stock, and very little cereals. Thus in 1871 he produced through stock at the rate of 3 cwt. of meat per acre, and in 1880 nearly double that amount. The forage crops on which he relies, and sown to come into use in due season are rape rye, ray-grass, crimson and ordinary red clevers, cabbage—the lien and thousand-headed varieties, and furze or whins. Beet and turnips follow in his rotation, and yield 30 to 35 tons per acre, the cabbage from 25 to 30 tons.

There is a tendency to cultivate cabbage more extensively than hitherto for cattle feeding. It is a very profitable crop near large towns for culinary purposes. No vegetable can be healthier; it is very rich in potash. In France a very nutritive soup is prepared with cabbage, potatoes, bread, and a little bacon. The French always give in cooking cabbage a good preliminary scald; this first water deprives it of much of its strong flavour. In the lands watered by the Mense and the Rhine, and their tributaries, immense plains of rich, argillaceous, and marly soil are cropped with cabbage destined to prepare. Saurkraut or choucroute, in other words fermented cabbage, and of which more anon. A good, white, close, cannon-ball—hardness of head is aimed at. In February a plot of 120 square yards, in the kitchen garden or a home field, is well prepared and manured; $3\frac{1}{2}$ ounces of seed is sown broadcast and raken in, the whole being covered with a slight coating of well-decomposed straw manure to keep the surface moist; if the spring be dry a watering may be necessary. That quantity of seed ought to yield about 15,000 plants.

The soil for planting out having the requisite tilth by ploughing, harrowing, and rolling, and enriched with 25 tons of farmyard manure per acre, the plants are dibbled in lines 32 inches asunder, selecting a humid day in April for the work. The after-culture consists in keeping the land clean. At the close of October the cabbage is fit for harvesting; each head is turned over on itself; a man follows to cut off the root and all green leaves; then they are piled in the cart, looking like snow balls, and to market. The selling price is from 20 to 30 fr. per 100, and if the yield per acre be taken at 6,000 heads, and the price 20 fr. per 100, the return will be satisfactory, as the expenses of cultivation and rent are about 280 fr. per acre.

Anglo-Saxons have yet to learn the utility of *choucroute* as an aliment; it is "grateful and comforting," and withal nutritive; it is an excellent aid during the winter and spring when vegetables run short. It is a standing dish on Continental tables. Then it is easily prepared; two implements: one to cut the stalk clean out, without disfiguring the head, and the other, a kind of jack-plane, with movable knives, to share the cabbage held in a bench into the necessary strips or shreds. These are put into a barrel having a false bottom, the empty space to be filled with water and changed in eight or ten days; place a layer of the shreds with alternate sprinkling of salt, and add some juniper berries; cover the top well with stones—not calcareous—placing a cloth over the surface of the upper layer. In ten or fifteen days it will be sufficiently fermented and can be used: 1 lb. of salt to 1 cwt. of "shavings."

To cook: wash it well with water several times and press the mass strongly, then place in a saucepan with some butter, lard is preferable, or even goose fat, simmer during five hours. A large quantity can be prepared at once, as it keeps well and re-heats admirably. With a slice of bacon, a sausage, &c., families and farm servants can feast like a king on the dish.

Implement Fairs are progressing in France; to these are now to be added Ambulatory Libraries of the best agricultural works.

The Exhibition of 1889 will give an extensive development on this occasion to the agricultural section. It is not unlikely that a special building in the suburbs will be devoted to implements and machinery, and no expense spared to test exhibits at work.

The supply of wine being now short in France, many farmers have planted orchards and so prepare cider. The latter is prepared by families to be adulterated and artificial beverages baptized wine, and which are innocent of all relationship with grapes. The pulp residue is employed for cattle feeding. Bossingault attests that very good eaux-devie can be obtained by preserving the residue in vats, well compressed, during six months, and then distilling the fermented mass. Made into a compost it is excellent as a top-dressing for meadows in the month of March; a little lime is generally added to neutralize the anti-fertilizing action of the tannin.

Many cows have suffered this season from poppy poisoning. The evil can be corrected by administering a mixture of vinegar, pure wine, and olive oil, to be followed later by an infusion of strong coffee.

This being the period for fattening grease, French farmers—to remove the strong flavour naturally of the flesh, a peculiarity with aquatic fowls—mix powdered charcoal with the food a few weeks before killing. Where the food is oil cake, this corrective becomes a necessity.

NATIVE AGRICULTURE AND IRRIGATION IN CEYLON.

If the native agriculturalists of Ceylon in their excusable ignorance will persist in jumbling together seed time and harvest, and planting at a season of the year which was never intended by Providence, and consequently fail to produce a crop, without coming to the Government to supply them with artificial means of irrigation, is the Government, in its inexcusable ignorance of the real wants of a people who do not know their real wants themselves, to continue to be misled by their representations, and carry on a policy, year after year, of throwing away large sums of money to encourage them to persist in their mistaken ideas without any material advantages to be derived by doing so? I would suggest that a series or chain of example farms or agricultural stations of a moderate acreage be established in each district of the island where the system of cultivation and irrigation may be carried on in a scientific manner.

In the course of time the success of some one of these stations must come to be observed by the surrounding cultivators who will be induced to adopt the same method of cultivation in preference to their own antediluvian system as soon as they perceive that the question of money is involved in a practice requiring less than half the quantity of grain used at present for seed. A spirit of emulation will be awakened amongst them. Its influence will spread and extend itself until it meets with that of the next district, and so on, until by degrees a universal system of improved agriculture will take the place of the old, and the dawn of prosperity begin for the whole Sinhalese race, and not only that, but an industry long neglected, owing to the widespread ignorance regarding its capabilities, will be made to rank in value alongside of any now being practised by the European community of this island.

When the Government has thus fulfilled its part, these example agricultural stations may be allowed to revert into the hands of private enterprize.

As a single instance amongst a multitude of others of the utter ignorance which prevails amongst native cultivators of the physical nature and capabilities of high cultivation of the very plant that yields their principal food, and their want of knowledge of propagating it according to the mode that nature itself points out to them, I may just mention this startling fact, which is worth the consideration of the Government in these depressed times, namely, that, if we take the whole cultivated acreage of Ceylon to be what it is supposed to be, 500,000 acres of paddy, no less a quantity than 1,125,000 bushels are every year actually wasted for seed grain, and the enormous sum of *Rupees one hundred and twelve thousand five hundred* uselessly thrown away, owing to their mode of sowing or planting, which does not admit of their taking advantage to the full extent of the valuable economic property possessed by paddy, as well as other cereals, of tillering from the root, when the soil is properly worked and brought by scientific means into a proper condition for the plant to do so. From paddy treated in this way I have obtained a return of nearly two hundred grains from the single seed.

With regard to the rice plant, artificial irrigation has a three-fold effect, although, as it will be observed, the first effect is produced by virtue of the actual necessity in the tropics of the second. Firstly, and by virtue of the second effect, it must necessarily supply sufficient moisture to the

roots of the plant, but no matter how much water may be applied, the plant can take up no more than what it requires through the spongioles of the roots. Secondly, the main principle in allowing the water to remain at a certain depth in a semi-stagnant condition, on the surface of the ground is because, in consequence of its being a bad conductor of heat, it prevents the radiation of heat caused by the sun's rays arising from the surface of the ground, and keeps the atmosphere for about two feet above the plant comparatively moist and cool, thus preventing the plant from being withered up owing to the property it possesses of evaporating its moisture from the leaves and stem faster than it can take in an equivalent quantity by the roots. Thirdly, the water being allowed to remain in a semi-stagnant condition on the surface must afford a valuable specific manure for paddy, for, wherever there is great evaporation over such a large surface as that of a paddy field, there is always the presence of electricity in quantities, or intensity varying in proportion to the extent of evaporation. This mysterious agent, in its action on the water and on decomposing vegetable or animal matter in the soil, splits them up into their constituent atoms, and thus supplies the plant with its carbo-hydrous elements.

From a series of experiments which I have conducted in the field in order to ascertain the least quantity of water required to be artificially applied to overcome the force of radiated heat and bring the paddy plant to perfect maturity, I find that that quantity is sufficient which just allows for filtration and daily evaporation.

This quantity, of conrse, must vary according to the general amount of moisture in the atmosphere of other districts, the color of the soil (the darker this is, there will be less radiated heat), and the way in which the soil has been worked up, pulverized and manured; but in Uva, one inch in depth of water per day, spread over the surface of the field, was quite sufficient, and a greater depth had no more appreciable effect. But during rainy weather and no dark cloudy days, with a moist atmosphere, no artificial irrigation was required, the plant deriving sufficient nourishment from the moisture held in the soil by capillary attraction only.—TAPROBANE.—Local "Times." [The statements that native rice cultivators use too much seed paddy, and injure instead of benefit in their crops by keeping them constantly flooded with water, are doubtless correct, but surely the Sinhalese and other natives are not so grossly ignorant as to confound seed time and harvest in the manner represented. There is only the assertion, but no indication of the change of seasons for sowing which the writer seems to advocate.—ED.]

SUGAR CULTURE IN THE AUSTRALIAN COLONIES.

In the *Tropical Planter*, a publication lately started in the interests of the sugar industry, the following instructive comparative statement of land under cane, acres of cane crushed, and sugar produced in Queensland is given:—

District.	Extent of land under cane 1882-83.	Extent of land under cane 1883-84.	Area of cane crushed 1882-83.	Area of cane crushed 1883-84.	Sugar produced during 1882-83.	Sugar produced during 1883-84.

Totals...	32,159	41,367	16,324	25,792	15,182	36,148

The total sugar production for New South Wales for last season was 15,723 tons of sugar.

According to the *Argus*, the consumption of the Australian colonies, including New Zealand, does not exceed 130,000 tons a year.

From the figures given above it will be seen that toward the consumption of 130,000 tons the sugar plantations of Queensland and New South Wales contribute 51,871 tons. To this has to be added the sugar production of Fiji, and refining sugar sent to colonial refineries from Java, Cuba, China, &c., not included in the above. To again quote the *Argus*:—"About 100,000 tons out of our requirements for the year are in view, leaving a small portion to be supplied from other sources. Besides Mauritius, an increasing trade is now being done with Bourbon, while China is sending down regular shipments, and is evidently looking for an outlet in these colonies for their surplus. Should exports continue on the same scale as heretofore from these countries, it does not seem improbable that, with our increased production, our market may be seriously affected by being overstocked."

From these facts it is evident that to hold their own the planters and manufacturers of sugar in the colonies will have a hard battle to fight in the struggle of competition. Practically shut out from the European market, the competition must necessarily centre more keenly in what hitherto may have been regarded as outside market. True, the demand—that is to say the consumption of sugar—is yearly increasing, consequent as much upon the reduced cost of the article as upon increase of population, but this increase is not in anything like the same rate as the increase of supply within the past few years, at all events. Some statistics with regard to the consumption of sugar per head of the population may, in passing, be of interest. In 25 years it has increased from 15 lb. to 65 lb. per head of the general population. This would give each individual a ration of nearly three ounces of sugar per day. In America, England, and Australia the amount per head is estimated at 70 lb. a head per annum, making the ration in these particular cases over three ounces a day. It is said that Mr. Gladstone remarked that the consumption per head would reach 165 lb. per head as society advanced. Why the consumption of 165 lb. of sugar a year per head, or nearly half-a-pound per day, should be a corollory of the advancement of society, is one of those enigmatical things that men, whose wisdom is supposed to be beyond question, occasionally utter for the bewilderment of their fellow-creatures.

THE MARYBOROUGH DISTRICT.

Maryborough, one of the oldest sugar district in Queensland, is situated on the River Mary, which, rising on the northern slopes of the main range, flows northward about 150 miles, through agricultural and mineral country, into Hervey Bay.

The following tabulated statement gives the acreage of the land under sugar in the district, yield, &c, from the season 1876 to 1877 to last season:—

Season—1st April to 31st March.	Area of Land under Sugar Cane.	Quantity of Cane crushed during Season.	Tons Sugar produced therefrom.
	Acres.	Acres.	Tons.
1876-77	2851	1851	2455
1877-78	3583	2331	2909
1878-79	4149	2996	3167½
1879-80	4285	3487	4763
1880-81	4638	3496	4157
1881-82	4981	3849	3570¾
1882-83	4760	3549	2147
1883-84	4842	3915	4880½

The president of the Planters' and Farmers' Association of Maryborough, at a late meeting, read a paper in which he stated:—

"I regret that, owing to the difficulty of procuring a regular supply of suitable labour, the future of the sugar industry is not so cheering as it was this time last year. Every year during the last four the supply of kanaka labour has been more and more limited and expensive. The seasons, also, during that period have not been so favourable for agriculture as those that usually prevail in the Wide Bay

country. The present crop, owing to the late drought, is very backward, and unless the rest of the winter continues mild, the output for the next crushing will be far below the usual average. The average yield per acre for cash of last four years was as follows:—1880-1, 23¼ cwt.; 1881-2, 18½ cwt.; 1882-3, 12 cwt.; and in 1883-4, 25 cwt. This gives an average for the four years of 18¾ cwt.; but the very satisfactory yield of the last year, viz, 26 cwt. per acre, was most encouraging, and the prices realised were so good that the whole value of the sugar produced in the district amounted to £140,000. It is as well to state how I found this money value, so as to avoid the appearance of inaccuracy. In the first place we see by the Government statistics that the total quantity of sugar produced in the Maryborough district was 4,880¼ tons. Of this quantity no less than 4,000 tons were manufactured by the Yengarie process; and this sugar being refined, it realised £30 a ton all round, or £120,000 in all. Then of the 880 tons remaining about three-quarters of it was made by the vacuum pan process, the rest by the open pan; and as the whole of the two sorts was sold in the local market, £22 per ton is within the average price. There was also 159,050 gallons of molasses, at say 1d. per gallon. I need only point out that these two items will yield over £20,000, and that the whole will make over £140,000, as before stated. Now there can be no doubt that this £140,000 goes into local circulation, or, at all events, the planter's share of it. For, after all that can be said in favour of the sugar industry, my experience is that sugar in this latitude costs as much in its production as it is worth in the market, taking one year with another, and allowing a fair percentage on the capital invested. The people engaged in it must stick to it, because they cannot afford to lose the money invested in machinery and other appliances."

CONCLUSION.

The employment of coloured labour, or labour equally reliable and equally cheap, on the sugar fields of Northern Queensland is, I am convinced, essential to the success of the industry, and my reasons for so thinking I will hereafter give; but I must protest against the position of martyrdom the planters have taken up. The present crisis has been precipitated by their own utter want of forethought, the selfish demeanour they have assumed, and also by their having stretched the bounds of the cheap labour they have had beyond its necessary, rightful, and legitimate lines of limitation.

It is my earnest conviction that the labour trade will never be satisfactorily carried out under the present regulations. Some system is required by which it can be controlled at the islands, and the only way that presents itself as feasible and calculated to attain the object desired is the establishment of recruiting stations at the islands, say one to each principal group, and under the command of responsible officers, whence by small steamers or sailing boats the work of recruiting could, within a reasonable radius, be conducted. Let the engagements be finally made at these stations, giving the boys time to think over the matter and thoroughly grasp the nature of the contract they enter into; and there, also, let them for a time be engaged in the cultivation of yams, taros, coconuts, &c., and in becoming accustomed to the manners of the white men, their diet, and, as far as possible, teaching them the language. Then let these boys be drafted off to the plantations. With reference to the plantations, let efficient means of inspection be taken in order to prevent the labour of the kanakas —unless in such cases sanctioned by official authority—being used outside of the drudgery of the cane-field and work associated therewith. Also make it compulsory that with each new arrival of recruits a sufficient quantity of yams, coconuts, &c., be brought from the recruiting stations to enable the boys to be gradually weaned to their new diet. Also, if it be practicable, define the hours of work according to the season, so that the boys may not be called into the field before the sun has risen in the winter mornings or be forced to work from 14 to 16 hours at a stretch in crushing time.

There is a class of extremists who say that if it be not possible to carry on the sugar industry without coloured labour then better than employ such labour let the industry perish, but there are, I think, few persons who, looking at the question fairly and dispassionately, would for a moment desire such an end. It would be of a piece with the act of that notorious individual who cut off his nose to spite his face. The value of sugar as an export, the immense impetus it has given to the development of the trade of the colony, the opening up and settlement by its means of lands that were before but pasture fields for cattle, and, not least, the effect it has had of employing directly and indirectly a great quantity of white labour, should, apart from many other reasons, place its importance to the colony beyond question. Hence I think it may be assumed that the desirableness of, at all events, maintaining the industry is generally admitted. Sugar has been the staple agricultural product of Northern Queensland for many years past, and the fact that no other tropical cultivation has there reached anything like equal proportions, may be taken as a proof in part that sugar in the crop that can be most successfully cultivated in that portion of the colony. It is reasonable to suppose that had any other crop been found to be more productive and more lucrative, it would have long since been started, and have taken the place of the less successful. If it be urged that trial of other tropical cultivation has not yet been made, that will be no argument against sugar-growing. It would be the very height of folly to check what is known to be successful in order to try some other, the success of which has not been assured, and is at the best but problematical.

As upon almost all points in connection with the subject of these articles, there is a difference of opinion. So also is there with regard to the possibility of white men being able in the climate of Northern Queensland to do the work of the black man. Upon this question of the white man and the climate there is much diversity of opinion, but it can at best be only taken as in the main theoretical, white labour in the canefields never yet having been thoroughly tested. Isolated instances of success or failure cannot be magnified into a general rule. Mr. Bashford, one of the largest railway contractors in Queensland, gives his opinion against the possibility. Whilst engaged in constructing a tramway at Mourilyan Harbour, the mortality among the labourers from malarial fever was alarmingly great, and during my visit to that district it was said that scarcely a man in the place but had had at some time or other an attack of fever; quinine and fever mixture were, indeed, among the staple drinks at the local publichouse. This certainly was the most unhealthy district I visited, and the number of complaints from men with pale, sickly-looking faces that they had never "rightly shook that fever off" was certainly not an inducement to me to remain there longer than was absolutely necessary. At Mackay and the Burdekin and Herbert, fever is also one of the evils the sugar planters have to contend against; and, as I have already stated, it is one of the principal causes of mortality among the coloured labourers. Now, against these facts is set the opinion of others, of whom Mr. A. Meston is a fair representative. Writing to the *Brisbane Courier* Mr. Meston says:—"I have previously asserted, and I again repeat, that white men can work as well in North Queensland as in the neighbourhood of Brisbane or anywhere else on the South Coast." The district of Mourilyan Harbour and the Johnstone River will, he thinks, be freed from fever when the dense scrubs are cleared and the land is under cultivation, permitting the sea breeze to reach the clearings from one side, and the tableland breeze to sweep them from the other. It will be seen from this that Mr. Meston argues not upon what is, but upon what may be in the future. In the meantime the dense scrub surrounds the plantations, and the sea breeze has no opening to cleanse the land of its malaria. Mr. Meston then quotes a number of instances of public works such as the railway from Townsville to Charters Towers having been constructed by white men in Northern Queensland. He further says, in the course of his lengthy letter—"During the three years of my residence in Northern Queensland I have paid special attention to the climate and its effect on all nationalities, and I find that the thermometrical temperature does not correctly indicate the degree of discomfort or oppression experienced by the individual. I have felt the actual sun heat more severely at Grafton, on the Clarence, at Ipswich, Brisbane, and Warwick than ever I have done in North Queensland, but I am bound to admit that in the tropics there is a slight feeling of lassitude and disinclination for exertion which is without doubt a characteristic of the climate. . . . When Mr. Bashford says Europeans cannot work on our north coast lands, his usual sound observ-

ation is at fault. Both Europeans and Chinese have worked for me, and many others, for the past two years, and I have carefully compared their performance. At some kinds of work the Chinamen will do as much as the European —that is, even work, or any light labour at which the perseverance of a weak man counts as much as the frequent 'spurts' and frequent 'spells' of a stroug man." Elsewhere, Mr. Meston states—"There are two formidable obstacles in the north to the employment of white men, and these are the refusal to work except at wages on sane planters can offer, and the disinclination to do any agricultural work whilst there is anything else available."

It may interest my readers to learn that years ago, when Queensland was comparatively an unknown land, the late Dr. Lang, after a visit, wrote:—"I hardly believe it possible that sugar, rice, or the iuferior kinds of cotton can be successfully cultivated wholly by European hands. I do not think that the continuous field labour under a tropical sun would be found compatible with the Anglo-Saxon constitution, and I cannot resist the conviction that if these articles are to be raised in quantities to have any commercial importauce, it must be by aid of Asiatic labour, as in the Mauritius."

It is not the man in the south who farms a few acres of sugar-land that feels the effect of a check in the supply of labour. He possibly utilises the cheapest of all labour—the hands of his children, and such men cultivate only in the south, near the centres of population. In the north the small farmer has his labour—either kanaka, wandering black or Chinaman—but seldom iudeed a white man in the field. The opponents of the planters in the north say the creation of large sugar estates and the encouraging of capitalists to settle on the land is a mistake, and that it would be far better to have the land in the hands of small growers, and that the mill would soon come where there was sugar to crush. A few minutes' reflection will show how impracticable such a scheme would be. In Northern Queensland the sugar plantations are large estates, excepting only those small farms which have become, as it were, parasites of the larger areas, being dependent upon them for a market and a livelihood. To clear these lands and erect mills upon them very large sums of money have been expended, and other large sums have been spent in opening up means of communication with the far distant markets for the product. In order to produce the first ton of sugar and get it to market, an expenditure of thousands of pounds has been necessary. How would it be possible for men without capital, the immigrant or small farmer say with his few hundred pounds to carry out such a work. To clear a sufficient area of land, in order to grow enough produce to keep body and soul together, would take the whole of his little stock, and then he would find himself in the midst of a forest uncared for and unthought of. No benevolent capitalist would erect a mill for him to crush his sugar unless there were a sufficient quantity to pay for crushing, and to do that, when the expensive nature of the machinery is considered, there would require to be thousands of tons turned out. Co-operation, combination, and so on is a thing we never find in such matters. No one is more jealous of his fellow than the man of little means. The capitalist attracts trade and population by making it worth while to go to him; but the efforts of the little men are not sufficient to pay others to do business with them alone. When the large mill and the large plantation have opened up the land, the small men having a market to their hand, can settle round about and benefit by that expenditure of capital which has been the means of making communication with the outside world. Lands that would still have been cattle runs have been made fields of cane, and new centres of white populatiou have been established; shipping has been extended, manufacture encouraged, and benefit given to all classes of the community by the investment of capital in the sugar lands of Northern Queensland, and yet the very people who have been benefited turn round and would refuse any share in the wealth of the colony to the men whose money has been the means of creating new avenues for labour and establishing prosperous communities, where a few years ago were but forest and scrub.

The question of the substitution of cooly for the present labour has been so fully entered upon in these articles, that nothing further need be said regarding it. The whole question is fraught with difficulties through the many interests involved in it, and in the many subsidiary, though not unimportant, considerations to be kept in view, and he who finds a solution of the matter which will give general satisfaction, neither wronging the capitalist on the one hand, nor on the other injuring the labourer and depriving him of his rights, will deserve the highest thanks, and, I believe, will win the hearty gratitude of his fellow colonists.

The views on a subject such as this of one whose knowledge of the question can at best be but cursory, and the result of hastily-gleaned information may not be of the gravest weight, but I think that the following words, written by the late Anthouy Trollope on the labour trade, are not unworthy of consideration. He says:—"An ill-conditioned enthusiasm may not only debar Queensland from the labour which she requires, but debar also these poor savages from their best and nearest civilisation."—*Sydney Mail.*

PLANTING IN SOUTH COORG.

For a good many miles after leaving Mysore the country is bare and very little cultivated. Then the road towards Coorg, which is bordered on both sides by trees, some old, and others newly planted, and all carefully looked after, leads through a jungle. This is composed of a great variety of shrubs and dwarf trees, many of them covered with creepers, and here and there, grassy spaces are interspersed. At Hunsur there was formerly a considerable European establishment in connection with the Remount Depot of the Madras Government. Of late years this has gradually dwindled down, and the depot is now in charge of a Sergeant. There are extensive works for the preparation of coffee, and the neighbouring jungle affords good tiger and other shooting, and for this reason the place is frequently visited by sportsmen. There is a trim Wesleyan Chapel, in which services are occasionally held by Missionaries of that enterprising denomination, and by visiting Chaplains. The soil in the Hunsur district is very poor, and the condition of the ryots is far from flourishing. Just below Hunsur, the road crosses a large river on a substantial stone bridge. The green grassy banks, and tall trees, and overhanging foliage are suggestive of home scenery. As usual the road is bordered by trees, and not far from Hunsur becomes one of the finest avenues to be seen anywhere in Southern India. The trees are large and well-growo, and the branches interlace overhead. This continues for several miles. Then the road leads into the heart of the jungle, which abounds with great clumps of feathery bamboos, hence the name familiarly given to South Coorg. There is abundance of good wood, which would become very valuable if the railway were brought nearer to it. Frequent streams pass merrily under the bridges, and soon became lost to view in the jungle at the other side. The road is in very good condition, in preparation for the marches of the 67th and 7th Regiments from Cannanore to Bellary, and *vice versa*. Coffee plants now shew themselves among the trees close to the sides of the road. In about six hours we had travelled twenty-three miles, and meeting a friend we started with him on a trap for his bungalow, perched on one of the loftiest heights in "the bamboo." The road, or rather path, led through coffee the whole way, for some five or six miles. Sometimes it went up hill, sometimes down, then along "the face of the brae" or by the side of water courses, where grew magnificent clumps of bamboo, mingled with giants of the forest. The prospect from the bungalow was very engaging. All around were ranges of hills—from 2,800 to 3,200 ft. high—planted to the top with coffee, but with a sufficient number of natural trees left,—for shade to the coffee,—to give them the appearance of being well wooded. On the most elevated peaks the white bungalows of the planters gleamed through the trees. To the south lay a vast plain, for the most part covered with primæval jungle. Bounding this plain, and running in an easterly direction, the Nilgiris stood out distinct. To the north and west were the richly-wooded hills around Mercara and the Brahmagery range, part of the Western Ghauts rising into great mountains.

The part of South Coorg devoted to coffee, covers, roughly speaking, twelve miles square. The estates are

carefully managed, and every acre is taken up, except patches in lowlying places, or marshes, where grass is grown. The most common indigenous trees are black wood, Indian walnut and jack fruit, with the smaller wild fig, orange and lime. The fig is often planted on estates to givemore effectual shade to coffee. Oranges are produced in great quantity, and with care apples and peaches also do well. In fact for orchards and market gardens the district is admirably suited. The residents would rejoice to have the railway to connect them on the one hand with Mysore and Madras, and on the other with Tellicherry and the Western Coast. Then the district would be easily accessible, and would have an outlet, not only for coffee, but for fruit, vegetables, wood and other produce. Coorg is celebrated for its wild honey, which is brought to Europeans by the natives, who collect it in hollow bamboos, and sell it along with the wax for very little. It is much improved when the bees are kept near a bungalow. Large earthen chatties are smeared with wax, and have small holes drilled in them, and are then placed in a quiet corner not far from the house. After the bees have taken possession of the chatties they are covered by a shed, and suspended from a beam in the roof. Formerly agricultural work was done by sorfs, the original inhabitants whom the Coorgs had dispossessed. Now, owing to emancipation and free trade in labour these hereditary bondsmen have, to a great extent, deserted the service of their old masters who have learned to plough and reap their fields, and tend their cattle themselves, and teach their sons to do the same. They are said to number between 30,000 and 40,000. They are a loyal and intelligent race.

The coffee industry has not been very remunerative of late, owing to over-production in other parts of the world, but it is looking up notwithstanding. This year the crop in Coorg will be below the average, and from a month to six weeks late. The planters have a good life of it in many ways, with a delicious climate, attractive scenery, healthy occupation, capital bungalows, and a pleasant society. The houses, with their polished timber floors and ceilings and other appointments, comare most favourably with the average bungalow in large military stations in the plains. The district is not a jungle, but a carefully kept garden. The presence of many charming ladies makes society very much what it is in more accessible places in India, while of tennis parties, occasional concerts and other gatherings there is no lack. Owing to the proximity of unlimited jungle good sport is to be had. The wild animals are deer, jungle sheep, wild pig, with the more formidable panther, leopard, cheeta, and an occasional tiger; and plenty of hares, snipe, teal, etcetera; and for a sensation, herds of wild elephants, which, however, are the sacred property of Government. —*Madras Mail.*

CINCHONA ALKALOIDS.

M. A. Lawson, Esq., Director of Government Cinchona Plantations, &c., Nilgiris, reports to the Secretary to Government, Revenue Department, dated Ootacamund, 25th Nov. 1884, No. 36:—In accordance with the promise which I made in my letter, dated 15th November 1884, No. 33, I have the honor to inform you that I have despatched to your address one gallon of De Vrij's extract of the cinchona alkaloids, which has been prepared at my request by Mr. Hooper. 2. Each fluid ounce contains twenty-four grains of the mixed alkaloids, or three grains in every teaspoonful of the mixture. The preparation may be diluted to any extent with water, acid fluids or with alcohol. 3. I shall be much obliged if you will kindly forward the bottles containing the preparation to Surgeon-General Dr. Cornish in order that he may, after due trial, give an opinion respecting its value. 4. I am unable to give you much information as to what the cost of Mr. Hooper's preparation would be if made upon a large scale, but I can give you the cost of all the ingredients which have been required to make the 10 lb. contained in the bottles which I have sent—

	£	s.	d.
10 lb. bark (Natural Red) at 10*d.* per pound (Madras rate, 17th November 1884)	0	8	4
Other ingredients	0	1	8
Total ...	0	10	0

or one shilliug per pound, each pound containing 384 grains of the solid mixed alkaloids. 5. The other expenses connected with the manufacture of the extract which would have to be incurred I am not able to estimate with any accuracy, but they would be distributed over the following heads:—

* 1. Evaporating pans; 2. Fuel; 3. Labor; 4. Skilled supervision; 5. Sheds or houses for manufacturing the febrifuge under.

The two bottles containing the extract referred to will be forwarded direct to the Surgeon-General.

CINCHONA CRUDE BARK.

On the 15th ultimo, Mr. M. A Lawson, Director of Government Cinchoua Plantations, Botanical Gardens and Parks, Nilgiris, wrote to Government, with reference to G. O., dated 4th idem, enclosing a letter from Dr. Cornish, the Surgeon-General, dated the 20th October, which has advertence to certaiu remarks which Mr. Lawson made in paragraph 62 of his Administration Report to Government ou the Cinchona Plantations. The Surgeon-General says in his letter "that the use of crude bark is very wasteful and expensive, owing to the fact that infusions and decoctions soon ferment in this country." With reference to this remark Mr. Lawson observes that in his report he made no mention of either an infusion or decoction being attempted. "Such a mode of administrating the febrifuge might undoubtedly be adopted, but the infusion or decoction would of course have to be made at the time it was required to be given to the patient; just as in England an infusion of senna is now made by the poorer classes. But even if this was done there would still result a considerable waste, inasmuch as a portion only of the cinchona alkaloids is removed by either of these processes. If, however, instead of the bark being infused or boiled it was to be steeped in some weak spirit, such as arrack, the loss of alkaloids would be extremely trifling, for a weak spirit dissolves out nearly the whole. If then a powder of a fairly constant value was made (and this could be easily done), I see no reason why it should not be sold in every country village, and the natives be allowed to obtain, either by instructions or by experiment, the amount of powder necessary for a dose. With respect to the suggestiou of the Sergeon-General, that the Government Quinologist should give his attention to the preparation of a fluid extract of cinchona, I am happy in being able to state that this is already being done by Mr. Hooper, and I forward by today's or Monday's post a small quantity of Dr. De Vrij's extract which he has made; and before the end of next week I hope that this gentleman will be in a position to furnish you with a further much larger supply for experimental purposes. The preparation which Mr. Hooper will send you will coutain a definite amount of the ciuchona alkaloids in every ounce of the fluid. I believe he intends to make the amount 24 grains to the ounce. This preparation, or any other, which the medical profession may determine te be the most convenient, can always be maintained without difficulty. Mr. Hooper's extract is not more uupalatable than the sulphate of quinine itself, and it possesses moreover this advantage, viz., that it may be diluted to any extent with water. The keeping properties of the extract will probably be great, but this is a matter which must be tested by experiment. The manufacture of the extract would be inconceivably economical, and could be carried on equally well on these hills or in Madras."—*Madras Mail.*

KOTAGHERRY.—Since I last wrote we have had really good rain, many estates registering as much as 35 inches in October, and today, as I am writing, we are enjoying a glorious burst of sun. Last month very little tea was manufactured, but this month so far has been a good one, and a good deal of lost ground will be made up. From invoices to hand all the hill teas had suffered a good deal from the prolonged drought, "want of flavor and weakness" being generally referred to by the brokers. Pruning has begun on most properties, and I fancy those men who began early will be fortunate, as there is every appearance of there being less frost than usual.—*Indian Planters' Gazette.*

* Out of every ten parts of the original liquor nine parts have to be evaporated off at 98° C. A great deal of the evaporation might be carried on in the open air without fire.

COFFEE AND TEA PLANTING ON THE HILLS OF CEYLON.

THE WEATHER—GOOD FOR TEA—RAINFALL—TEA PRUNING AND FLUSHES—CROP AT A HIGH ELEVATION.

LINDULA, 29th Dec. 1884.

There has been a complete change in the weather and the surface of the ground looks as dry as if the heavy rains between the 10th and 19th had never fallen. But in shaded spots and in forked-up earth abundance of moisture is apparent. We have now the true end-of-the-north-east-monsoon-weather, in the shape of cool, indeed *cold*, nights and mornings with blazing hot days. Last night the thermometer here (elevation 5,800 ft.) went down to 52°, while as I write at half past 1 p.m. it marks 70°. The whole vast series of mountain ranges is clearly defined and scarcely a speck of cloud is visible, although as evening approaches, we may expect a recurrence of yesterday's phenomenon. Volumed masses of cloud appeared over Dikoya and Maskeliya, more snow-like than anything to be seen out of the Oberland Alps in Switzerland. "Presage of a hot, sunny morrow," was our remark, and our anticipation has been fulfilled. A temperature of 70° up here is quite the equivalent of 85° at Colombo. Such weather, following on abundance of rain, is most favourable for tea; all except the seedlings put out about a week ago, which are drooping but which, owing to the moisture in the soil will probably hold their own. For flush, nothing better could be desired; and the same may be said as regards the coffee crop now ripening rapidly—what there is of it. Here we are likely to get 2 000 bushels instead of the 8,000 at least which would be due had the fungus pest not intervened with its desolating and deadly influences. But even the 2,000 form a considerable improvement on last year, and black-bug not having put in an appearance here, the coffee trees look fresh and clean after the recent washing they have received. We should entertain sanguine expectations regarding "next year," but for past experience of virulent attacks of *Hemileia vastatrix* following immediately on apparently total exemption from the plague. How fervently we wished the realization of the prediction we heard from a traveller yesterday, that in a few years the fungus would disappear from the coffee, except as a partial and insignificant affection. What we know as matter of fact is, that since the latent pest emerged into activity and notice in 1869, it has, not only spread over all Asia and portions of the Pacific, but that it has found its way to Africa and is likely, therefore, to be soon heard of as infesting the indigenous plants of Central Africa and Abyssinia. Whether the exotic coffee of Southern and Central America are destined to preserve the present immunity from this worst of all "the enemies of the coffee tree," remains to be seen. The probability seems to be that the fungus will ultimately be co-existent with its special food. On the other hand it is no more conceivable that coffee will be entirely snuffed out of existence by a pest, than have been the potato and the vine. It is on a patch of tea and not on coffee that the scale insect has been seen up here, and this will be the subject of notice subsequently. The really heavy rain ceased here with 0·22 of an inch on the 19th, and only 0·16 have fallen since then spread over four rainy days, 0·07 falling in a gentle drizzle yesterday. The total rainfall of the expired portion of the month has been 6·30 inches, against the Langdale average for the whole month of 4·57. It is possible that enough rain may follow the present heat to make up 7 inches for December.

In that case the rainfall for the twelve months will be :—

January	... ...	0·61 inches.
February	... ...	0·72 ,,
March	... ...	6·34 ,,
April	... ..	1·12 ,,
May	... ...	5·80 ,,
June	... ...	9·00 ,,
July	... ...	11·19 ,,
August	... ...	14·39 ,,
September	... ...	7·85 ,,
October	... ...	12·86 ,,
November	... ...	8·45 ,,
December	... ...	7·00 ,,
	Total...	85·33 inches.

against 100·10 last year and an average of 110 inches. There has thus been a re-action in the past two years against the abnormal rainfall of 1882, when about one-fourth above the average was recorded.

The past year, or rather the year just closing, has been favourable for tea and an average of 500 lb. an acre will be shown at this elevation of 5,000 to 6,000 feet. As a considerable portion of the plants were pruned at a period which lessened flushes in the best months, it is reasonably anticipated, that, if meteorological conditions are not specially adverse, fully 600lb. per acre will be picked and cured next year. A Darjeeling planter objected to nipping off the tops of tea bushes at an early age, that, although lateral growth might thus be promoted, it would be at the expense of robustness of stem. Experience here has not verified this theory: the early topped trees shew good surfaces and equally good stems, and growth altogether is wonderfully luxuriant. Our most formidable enemy as yet is a "poison tree," the stem and roots of which kill a good many plants, but of this more hereafter.

JUST THE WEATHER FOR TEA-FLUSH—NO BLIGHTS OF ANY KIND VISIBLE—PLUCKING A CHECK ON INSECTS —POISON TREES.

LINDULA, 30th Dec.

Yesterday, before my letter was dispatched, the sky began to darken; and last night the temperature was so mild, comparatively, the mercury going down to only 57°, that we anticipated what has come to pass, a gentle drizzling rain occasionally, just the weather for the tea-flush and equally good for ripening up coffee. I mentioned that coffee showed no signs of leaf disease, and I have now to add that I have never before seen the tea bushes so clear of blight of any kind. There is no sign even of the little white moth, which has hitherto been our chief trouble, and no *second* specimen of *Helopeltis Antonii* has been discovered. When the one specimen which was sent to Dr. Trimen was found with a few other bugs of a kindred nature, strict search was made for affected leaves, and all found were destroyed. Ever since, too, the pluckings of "flush" have been frequent, and I think there is much force in the remark of the superintendent when I expressed my surprize at the entire absence of insects: "We pluck so frequently—on an average once a-week—that the insects do not have undisturbed periods sufficient to breed in; and our constant pickings and consequent shaking of the bushes in Ceylon must tend to give us greater immunity from blights than is the case in India where the bushes lie untouched sometimes for thirty or forty days during flushing time." Be the reason what it may, since the disappearance of bug from "the cattle-shed field" (where it hindered flushing but left the trees uninjured), the clean condition of the luxuriantly flushing tea has been most satisfactory. The only exceptions have been a few of the large seed-bearers, from the stems of which

patches of moss had to be rubbed off. The remedy is to keep the soil stirred about the roots of such trees, as to prevent the growth of moss on the surface of the ground. The chief enemy of the tea tree we have to contend with at present is a subterranean one, in the shape of the decaying roots of the "poison tree." Our attention was first directed to the baneful effects of this tree in 1879 by an experienced planter from Assam, who asked: "Do you not lose patches of plants growing round a certain tree?" Up to the moment we had not noticed anything of the kind, but our visitor soon came upon a vacant spot and showed us the cause. We ought then to have done what we are now doing, that is, employ a gang of men to go round uprooting the destructive tree, around which from two to twelve bushes have died at from three years old to eight, when, as we have reason to believe, their feeding rootlets come in contact with the poison in the roots of this "Upas." It has been suggested to us that the destructive agents are fungi or baccilli developed in the decaying wood, in which small white fungi are certainly abundant; but we have learnt from the intelligent head-carpenter of this estate that the tree is notorious amongst his people for its poisonous juice, resembling, he said, the juice of the Euphorbias in its milky appearance and its blistering properties. Until today we have been unable to identify the tree further than that Mr. W. Ferguson pronounced it to be a *symplocos*, from the twisting habit of the fibrous timber, no doubt. But we have now obtained specimens of the foliage, bark, stem-wood and roots of the living tree, which, with portions of the decayed roots we intend to send to Dr. Trimen for such remarks as he may have to offer. I am sorry we cannot at present obtain flowers or fruits, but the carpenter describes the blossoms as white, small and inconspicuous. The foliage, on the other hand, is most conspicuous; the leaves being large, glabrous and light green in colour. The tree does not attain a large diameter at this elevation, but lower down, the carpenter tells us, it is a big tree. But everywhere it is useless either for timber or firewood. The carpenter spoke of it contemptuously as commencing to decay as soon as it was cut down. In the burning of felled jungle it is described as sending forth a noisome smoke. In cutting our specimens today, surprize was expressed at the absence of milkiness in the juice, which only showed slightly in the root pieces. The juice may probably assume the consistence and colour of milk only at certain seasons. But there can be no doubt the trees pointed out to us in the standing forest today are our enemies of the tea fields. Comparison of the green wood and the decayed roots was quite conclusive, and we advise all tea planters to lose no time in rooting out from amongst their bushes, the stems and roots of the tree known to the Sinhalese as *diya ala-hera-liya*, the vulgar name being *lab-labu*. "Labu" means a pumpkin, and "diya-ala" means a watery yam, the names being descriptive of the tuberous juicy roots. The leaving of the roots of the tree in the ground here has cost us at least the loss of 10,000 tea plants in stages advancing to maturity.

There is another poison tree, the *badul*, known to the Tamils as *muha-vingi maram*, "the face swelling tree." A man from this estate had to be sent to the hospital for treatment in consequence of the serious swelling of his face which followed a squirt of juice from a badul tree which he had struck with his axe. But we have not traced any loss of tea to this tree, although the root resembles that of the tree which has done such harm.

PERFUMES IN FLORIDA.—It is said that the perfume industry in Jacksonville, Florida, is yielding products fully equal to the best French articles.—*Gardeners' Monthly.*

PLANTING IN JAMAICA.—No. II.

THE "BLUE MOUNTAIN COFFEE" DISTRICT OF JAMAICA—PRICES RANGING UP TO 140s. PER CWT—TRANSPORT BY MULES—COFFEE TREES 60 TO 80 YEARS OLD—COMPARISON WITH UVA—CULTIVATION IN JAMAICA—JOB WORK—MR. AND MRS. QUASHIE.

Blue Mountain District, Jamaica, 1st Nov. 1884.

I take advantage of a wet day to commence my second letter, and purpose telling your readers about the well-known *Blue Mountain* coffee district of Jamaica, which produces such a very fine bold samples, and which still fetches very high prices in the Liverpool market, such estates as "Cold Spring," "Chestervale," "Radnor," "Whitfield Hall," Pleasant Hill," "Clydesdale" "Sherwood Forest;" have lately realized from 127s. to 115s. for their best, and last year in face of low prices one tierce of "Arntully" sold for 140s. These are prices which in some measure make up for a sm,all average bearing per acre, and a higher wage than is paid in Ceylon and India. The Blue Mountain range is situated at the Eastern end of the island, the Peak rises 7,360 feet above the sea, the range is very bold, and runs off into many spurs on which some of the estates are located. Above Kingston rises the "Port Royal" range, the highest point of which is about 4,500; it is separated from the Blue Mountains, by the "Yallaho" river, a stream with a very broad bed, but except when in flood very easily fordable. In the old slave days these "Port Royal" hills were covered with fine coffee properties, but it is now very melancholy, to see the abandoned works, and stone houses in ruins or perhaps only a few patches of coffee kept up in the hollows, by people who have purchased the property for a trifling sum. There are now only two or three properties on the Port Royal hills, producing sufficient coffee to make them worthy the name of a coffee estate. On an average the Blue Mountain estates may be said to be 20 to 25 miles distant from Kingston, only 9 of which are cart road, the rest is a steep bridle road, in some places tolerably broad, but in many spots very narrow, scarped and dangerous; all transport therefore to "Gordon Town," the terminus of the cart road, has to be done by mules or by head loads. A mule will take down 200 lb. coffee (100 on each side) and costs 3s. to 3s. 6d. if by hired mule, but most estates keep their own stock, and there is generally an enclosed pasture on every estate for the animals, taken from some of the old abandoned coffee, or the negro grounds of the old slave days.

To compare the Blue Mountain range with any district in Ceylon I would select "Onvah" and specially "Hapntale" and "Uda Pussellawa"; for in soil, climate and steepness of land they are not unlike; the coffee is equally fine, and even trees 60 to 80 years old respond most gratefully for kind treatment, simple weeding and pruning work wonders, the soil and climate being so excellent. But Jamaica lacks the noble Uva "patenas," the terraced paddy fields, and the Kandyan villages nestling amongst their coffee, plantain, jak and arecanut trees. In lieu thereof the hills are very steep and precipitous, the valleys narrow and admitting of no cultivation; but we have a grand prospect of mountain and ravine, and the glorious sea 8 to 10 miles off as the crow flies.

As to cultivation a Jamaica coffee plantation is very behindhand, as compared to upkeep in Ceylon 10 years ago, and in appearance quite different, for in Ceylon estates were commonly 200 to 300 acres in extent, all in one large field; what Ceylon planter does not remember "Rothschild," "Delta," "Meddacumbera," "Gampaha" and "Spring Valley." In Jamaica, the fields are mostly small, and all detached, suitable spots have to be selected, where there are flats, or nice hollows amongst the hills. The largest

estate in Jamaica is about 200 acres in extent, and the finest about 160 acres, but covering a very much larger area from end to end; the latter possesses some of the largest fields in the district and is a very fine paying property; it has yielded at times 100 tierces, which with a moderate expenditure, and prices netting about 100s, must leave a good profit.

Three or four weedings a year have I believe, been the rule in Jamaica of later years; nor does it follow that the trees are pruned and handled every year; no doubt bad times, scarcity and dearness of labor have contributed to this mode of culture, and as I have before said, the soil and climate are so fine that the trees do not suffer, as they would in Ceylon—the *one* advantage of the system is that the land being weedy often saves wash on these very steep hillsides. I am determined to keep my new fields decently clean, and weed them at least once in six weeks, and have already introduced the use of iron scrapers, and small weeding hoes.

Most planters seem to prefer *job* work when it can be given, for the Creoles then work with a will; at day labor they are harder to drive than coolies, and being so independent, living on their own grounds, and being pretty well off, one has to be very careful in the treatment of "Mr. and Mrs. Quashie." On this property we are fortunate in being near to large settlements, so are better off for labour than many others less favourably situated. The prices of labor range from 1s to 1s 3d for men and lads, and from 7½d, fd, 10½d to 1s for small boys, girls and women. In crop time no doubt, women can earn more picking br the "Tub" "which is a vessel, beating our Ceylon "boxes" hollow, as it holds two Imperial bushels oy 64 quarts loosely cut. On most of the estates the cultivation is now generally at the top, as the lower lands are either worn out or are too steep for cultivation, for instance this house is 2,900 feet above the sea, and my principal fields between 4,000 and 5,000 feet, so I have a good climb to my work, and always ride up, as it is such a long distance to come down, have my breakfast sent up to the field. We only get four days work from the people, on Fridays they work in their own grounds, and Saturday is general market day; none of these people live on the estates, but various distances off, some two or three miles away, and they do not muster till 7 o'clock, and have the aforesaid climb at a slow pace, and moreover have an hour allowed for breakfast, each gang having a cook to prepare it (relic of slave times), the Jamaica coffee planter does not get much more than 7½ to 8 hours' actual work out of his people. Coolies who have served their time are well off, as they are housed, and if able-bodied get 1s 3d a day.—W. S.

REVIEW OF PLANTING OPERATIONS IN CEYLON IN 1884.

TEA—COFFEE—CACAO—RUBBER—ARECA—BREAD-FRUIT—COCONUTS—RICE—CINNAMON.

Tea is fast usurping the position of 'king" among our planting staples. Very great is the area planted with the new product duri g the past year, and not the least over old coffee land; but we refrain from an estimate of the extent, seeing that before long, in connection with our Handbook, we hope to have information as nearly correct as it is possible to obtain. The utmost activity and very great hopefulness at present prevail and not the least feature is the firm belief of natives—Kandyans especially—in the permanent character of the new plant (tea). A striking illustration of this fact was stated to us the other day by a Visiting Agent who had occasion to travel across country from Gimigathena through Yacdessa—once "the classic" land of Caledonian and Saxon coffee planters—where after some miles of walking he came on an unused grass-grown estate cart road. Meeting a Kandyan he asked him, who had constructed this road and was told it was made for the coffee watties on the hillsides above (now grown up in chena) by Harper Mahatmeya—(curiously Mr. Forrest Harper returned to Ceylon again a few weeks after this occurrence)—but that the coffee had ceased to yield and had become choked by weeds and scrub jungle. 'Well then, may not the tea, the new plant, go out in the same way?' was the rejoinder. 'Oh no' was the reply, 'this is a jungle plant itself—it grows as quickly and as strong as any of the weeds or jungle stuff'! It is certainly a fact that patches of tea which were neglected or abandoned in the crisis a few years ago, have held their own against all intruders and grown apace, in a way that never could be said of coffee. As to coffee, the past year opened very favourably and it closes with good prospects on the whole; but the drought told on the filling out of the bean, especially in Uva, so that "light parchment" became the rule and the deficiency in crop was very lamentable in consequence. Our estimate framed early in October for the exports of season 1884-5 was 385,000 cwt. (against 360,000 cwt. given two months later by our daily contemporary); but from all we learn now, we doubt if more than 320,000 cwt. will be made up. On the other hand it is very certain that of cinchona bark we have still such reserves that if the price continues encouraging we can ship during the present season a good deal more than we ventured to estimate. There are indeed some of our mercantile authorities who say they expect the outturn to be as large as in the previous season and certainly an export of 10 million lb. is not unlikely in the face of nearly 2 million lb. already shipped to 31st ult. against 1,650,000 lb. in the same period of 1883-4. The scare which arose over "Cacao" in connection with the effects of drought, want of shade and of Helopeltis during the early and middle part of 1884, has nearly died out and the plantations well established in the Kandy and Matale districts are recognized as permanent investments of value. Among new and minor products croton oil seeds and coca leaves are beginning to attract attention; while the collection, preparation and shipment of silk cotton (kapok) for mattress stuffing and other similar purposes, have given employment to a considerable number of natives and formed an acceptable addition to our shipping trade in a time of depression. The absurdity of expecting immediate returns from rubber trees is now recognized, but those who are persevering with the enterprize expect to have properties nearly as valuable and permanent as those under the coconut palm. The way in which the cultivation of the latter and of other fruit trees has extended among the Sinhalese in the South and West and far into the interior along the Valley of the Mahaoya shows how readily the people and especially the capitalists, discover the enterprize which best rewards their labour and investments. There are signs that native attention is now being given to tea and we quite expect to see the Ceylonese—Sinhalese and Tamils—become owners of tea gardens all over the divisions of the island with a suitable climate. The cultivation of arecanuts long a profitable industry with natives has attracted the attention of Europeans and with satisfactory results; a new and better kind of nut has been introduced. This reminds us of the need for introducing a better kind of breadfruit than at present is found in Ceylon: that careful horticulturist Mr. W. H. Wright has long been urging the Government to obtain the best species from Australasia or the South Sea islands and we trust this may be accomplished in Sir Arthur Gordon's time. The following communication from an old planting resident gives a retrospective glance over the year that is gone,

from a special point of view :—

"In looking back on the results of planting operations of the past year, I think there can be little doubt that the lowest depth of depression was reached in 1883, and that the improvement anticipated by you and many others has been fully realized.

"*Coffee*: Though the greatest and most fatal of all the calamities that ever visited the island, is still undiminished, and prices have been almost as low as they ever were, crops have on many places been better, and estates that have been well cultivated have given good results, and by their vigorous condition show that it is possible for coffee to be enabled to resist the ravages of the disease, and be kept in heart for that good time that after all may not be far distant for the old staple.

"*Cinchona* has certainly done no worse than in 1883, and the recent rise in the price of bark is encouraging to those who are fortunate enough to have thousands of trees still growing.

"*Cocoa*.—The disease that at one time appeared so alarming has turned out to be not so serious as it threatened, and is probably, in a great measure, the result of exceptional dry weather. There does not appear to have been much extension of this cultivation during the year: in fact, the extent of land suitable for it must necessarily limit the acreage.

"*Cardamoms* have been quietly planted up in many districts, and generally with satisfactory results. The principal drawback to their cultivation seems to be, the depredations of thieves; the produce occupies so little space, that it is very tempting to the villagers.

"*Tea*.—The most sanguine expectations with regard to this product, have been fully realized, both as to yield, and the rapid growth of new clearings, and it is now beyond all doubt, that Ceylon is destined to be a great, if not *the greatest* tea country. A very large acreage has been planted up in 1884. I cannot venture to estimate the figures, but there is scarcely a district that has not contributed an addition to the great expanse of tea that is now steadily spreading over the whole Central Province, not in small experimental clearings, as at first, but with the confidence of certain success, in fields of 100 acres and more, in both new and old lands; and in the latter coffee that did not pay for cultivation has been remorselessly pulled up, to make room for its more prosperous rival.

"Vast as is the tract of land suitable for tea, in Ceylon, there is a growing demand for land in districts found to be favourable, a considerable rise in the value of property has been the result. Old estates have exchanged hands at prices that would have been deemed incredible a few years ago, in fact somes of them would have been put down as almost valueless. Of course it is a mistake to think that it will pay to grow tea on any soil, but there can be no doubt that it will grow well and give paying crops, on land where coffee has failed, and where nothing else we have hitherto been acquainted with, would pay. Improvement in tea machinery may also be put down amongst the gains of the closing year, and the readiness with which they have been adopted and the skill and care Ceylon planters have brought to bear on the new cultivation is a guarantee that Ceylon will take a first place in the preparation of tea as she did in that of coffee.

"With the success of tea cultivation so well established the planting prospects for 1885 in Ceylon are decidedly brighter, and promise to many a happy New Year."

From our bi-weekly contemporary of the "Examiner" we take the following reference to low-country native products for the past year :—

"The paddy crops throughout the island have suffered more or less from the prolonged droughts which marked the beginning and middle of the year; and large tracts failed to yield much more than the seed which was sown. As a result there has been considerable distress among the poorer classes, aggravated, we regret to think, by sickness, and by the relentless recovery of taxes. It is to be hoped that the large sums which have been voted for Irrigation will be profitably spent, and will render the cultivator less dependent on rainfall than he is in too many parts of the island. Coconuts, on the other hand, a product which also is chiefly in native hands, have fully realized during the year the expectations formed of them and have generally yielded satisfactory returns to proprietors. Flowering as the tree does every month, and taking a full year to mature its fruits, prolonged droughts cause the dropping of the immature nuts; but the losses caused by two or three scanty pickings have been fully compensated for by satisfactory prices. Although the price of coconut oil has disappointed those whose experience justified the expectation of an increased demand during the winter months, copperah has been extensively purchased for export, and has made the growers to a great extent independent of the local manufacturers of oil. This is a comparatively new demand, and has led to considerable activity in trade, and, if continued, promises to benefit the natives very largely. Cinnamon, however, has shown no signs of recovery, and can have yielded adequate returns only to those who combined systematic cultivation of the shrub with most careful preparation of the bark—by no means the least important of a superintendent's duties. Monthly sales have failed to arrest the downward tendency of prices; but those who have persuaded themselves that frequent auctions are the cause of the present prices forget that low prices commenced with quarterly sales, that they were then referred to over-production, that production has since increased, and that other products, in the sale of which there has been no change, have also suffered from a falling market. We should not object to a reversion to quarterly sales by way of an experiment; but we continue to believe that the intervals between the sales have far less influence on prices than production. If the market continues to be stocked with cheap and coarse bark and with chips, prices must continue low; and if intelligent men refuse to set a good example to their ignorant neighbours, they must suffer in their pockets. A fair compromise would be for the advocates of monthly sales to withdraw their objections to quarterly sales, if the believers in the latter consent to abandon the scraping of chips."

The first part of 1884 was remarkable as being one of the driest seasons throughout the island on record: the south-west monsoon was an almost entire failure in several districts and notably in Matale East, where the "oldest inhabitant" declared that not in the present century could so dry a year be recalled. Most promising fields of cardamoms were irretrievably damaged so far as the current year's crop is concerned, and other crops greatly affected. The effect on tea-plucking was also observable; but this need create no alarm for the future since the season was so markedly exceptional.

QUEENSLAND ACCLIMATISATION SOCIETY.—The following are some of the plants, seeds, &c., which were received during the past two months (July and August), namely:—From F. J. Ivory, Brisbane, seed of native bottle-tree; from J. P. Williams & Bros., Ceylon, seed of *Cinchona ledgeriana, C. Calisaya, C. officinalis, C. hybrid, C. Robusta, Cardamom robusta*, Malabar cardamom, divi divi, eroton oil, sappandy wood, Ceara rubber (printed directions as to the cultivation of cinchona and divi divi can be seen at the society's office); from L. A. Bernays, F.L.S., Brisbane, seed of Dinde, said to be the best timber tree of Columbia, of three varieties ornamental grasses, and of varieties of nasturtium; from Botanic Gardens, Mauritius, case of various plants; from Dr. Bancroft, plants of asafœtida, rare native orchids, variegated lantana, cuttings of a variegated maclura, seed of seedling grapes; from R. S. Hews, Brisbane, seed of *Jacaranda mimosifolia;* from J. W. Stewart, Daintree River, seed of Davidsonia plum and of native banana, plants of rare native ferns, orchids, bamboo, &c., from R. Harper, Ipswich, seed of *Jacaranda mimosifolia;* from Botanic Gardens, Toowoomba, various *Conifera*, &c. During the last three months 4,630 plants have been distributed either to members of the society, public institutions, or as exchanges. Seeds have been gathered of teak (first time of ripening), *Spondias dulces*, &c.—*Queenslander.*

Correspondence.

To the Editor of the "Ceylon Observer."

PRESERVING VITALITY IN TEA SEED.

Overdale, Dunblane, Perthshire, 1st Dec. 1884.

SIR,—In your issue of the 13th October, *Enquirer* asks "the best way for packing tea seed, to be kept out of the ground nearly two months after packing?"

About three years ago, I recollect the same question being put in this part of the world without for a time eliciting anything more satisfactory than is to be found in Colonel Money's book. At length in the columns of the *Glasgow Herald* of 24th September 1881, a letter to the Editor appeared headed "Successful Experiments in Tea Planting," and signed "Stuart Cranston." Mr. Cranston is a tea dealer there, and it appeared that a friend of his, Mr. R. D. Cruickshank, a returned Assam tea planter of ten years' experience, had made the discovery in India that tea and other similar delicate seeds can be kept sound and vital for a considerable length of time if packed in air tight boxes amidst perfectly dry mould. He recommended the use of strong, loamy soil which had been thoroughly dried in the sun, afterwards broken small, then passed through a fine sieve; and it was stated in the letter that tea seed had been kept sweet and in life for fourteen months by that simple plan, germinating readily and without appreciable loss at the end of the period. As a visible proof of the honesty of the assertion it was further mentioned that before leaving India, Mr. Cruickshank had gathered some tea seed on the 1st November 1879, preserved it in dry earth hermetically sealed tins, and had it planted near Glasgow in one of the Garscube hot houses on the 20th June 1880. Every seed germinated, although the removal from tropical Assam to temperate Lanarkshire, and an interval of nearly eight months, must have proved a crucial experiment. Some of the resulting plants, then about a yard in height, were afterwards exhibited in the windows of Mr. Cranston's shop, No. 76, Argyll St., Glasgow, and had been seen, examined, and admired by thousands of the citizens before the *Herald* letter above alluded to appeared.

On observing the inquiry in the *Ceylon Observer* of 13th October, I wrote to both gentlemen and I am informed that the dry earth system of preservation has been well-tested since: that tea seeds have through its agency retained their vitality for two years, and have yielded when planted, eighty per cent of seedlings. —I remain, sir, your obedient servant,

WILLIAM COCHRAN.

[This plan for preserving seed—dry earth—has been successfully adopted by some of the large dealers in delicate foreign seeds in London, with satisfactory results.—ED.]

TEA MACHINERY: KINMOND'S TEA ROLLER

29th Dec. 1884.

DEAR SIR,—In your issue of the 27th you publish a correspondent's condemnation of Kinmond's tea rolling machine. This machine, I believe, bears a good reputation in India, and I have heard it well spoken of in Ceylon, presenting as it does to the ordinary mind advantages over various other rollers. Your correspondent would therefore confer a benefit on the uninitiated by explaining the defects that become apparent after continuous working.

It would be of immense benefit to the tea industry in its present stage if the merits and demerits of machinery were openly and impartially discussed. I would therefore propose that managers and superintendents now having practical experience record their opinions of the various machinery in use. Jackson's roller seems to carry the palm, but we have heard great things claimed for the "challenge," the "brush action," the "Kinmond," &c. What are the results of experience? Firing and drying and sifting machinery and other tea-house appliances might also be publicly criticized with advantage to the tea industry and the most deserving makers.—Yours truly,

NEUTRAL.

INDIGENOUS TEA PLANTS.

December 19th, 1884.

DEAR SIR,—Will you kindly allow me, through your columns, to ask of those of your corresponnents who have already gained Ceylon experience with indigenous tea plants, the following two questions, viz.:—

1st. What is the most suitable distance to put out indigenous plants for seed-bearing purposes?

2nd. Is it advisable to put them out as supplies amougst hybrids?—hybrids of course being all cut back for leaf.

I have referred to Money's work, also to 1st volume of *T. A.*, for possible replies to these questions; but unfortunately hard times prevent me from further access to the latter work.—Yours respectfully,

HARD TIMES.

MANURES FOR SUGAR PLANTERS.—I would direct the attention of sugar planters, to whom the improvement of their crops is now of such vital consequence, to the export price list of superphosphates and concentrated manures issued by Messrs. E. Packard & Co., of Ipswich. All their superphosphates and special manures of every description are sold by analysis, and will be based upon the analysis of each consignment; and the chemist, Mr. Packard state, may be selected by the buyer from any of the well-known public analysts of London. The demand for phosphoric acid of great purity, and in a form easily soluble in water, has been created by the Bernard-Ehrmann process in the manufacture of sugar, and, at the suggestion of Mons. Erhmann, Messrs. Packard have commenced the manufacture of a substance which they call Erhmannite, containing 'fifty-five per cent of phosphoric acid, all soluble in water, and non-deliquescent." [See *Advt.* elsewhere.]

TEA.—The efforts of Russia to establish tea cultivation in the Trans-Caucasus are brought to notice with some emphasis by Mr. J. H. Elwes, our representative at the Botanical Exhibition and Congress held last summer at St. Petersburg. Mr. Elwes was not able to visit the scene of the industry himself as he wished to do, but what he heard was enough to make it evident that a vigorous endeavour will be made, with every assistance from the Government, to monopolize the supplying of the Central Asian markets. There is nothing of course that is surprizing in this, nor is the Indian trade likely to suffer vitally if the attempt is successful. The only serious thing, most people will think, is that the Russian Government should bother about planting in Caucasus at all, seeing what her expectations are of coming into so much better a property in Himalayas.—*Pioneer.*

NOVEL APPLICATION OF INDIARUBBER.—In a recent number of the French journal *La Nature*, we have an account of a new, curious, and original application of Indiarubber. The inventor manages to give to various household objects in earthenware, porcelain, glass, &c., a remarkable adherence to the body supporting them. This result is obtained by the simple expedient of forming a swallow-tail groove in the bottom of such objects, and fixing therein a projecting band of vulcanised Indiarubber, forming a kind of circular cushion. Objects thus furnished are almost incapable of falling from their places. It is said that they may be placed on a wooden table, and the table inclined to an angle of 45 or 50 degrees without their being upset. It is evidently in the supply of table services for use on board ship that this invention can be most directly utilized. It will also be found advantageous for nursery tables, and for invalids taking their meals in bed, &c.—*Indiarubber and Guttapercha Journal.*

TEA-BLENDING AND CEYLON TEAS.

A copy of the "Tea Trade Circular" of December 1st of Messrs. Lewis & Co. (Tea importers and wholesale dealers, Crutched Friars, London) has been sent to us, in which we find our article of two months ago on "Tea Culture and Profits in Ceylon" reprinted bodily, without any acknowledgment; and on another page "Chapter IX." of a paper on "Tea-blending" which in treating of "Ceylon Teas" may be quoted as follows :—

On another page we give an exhaustive account of the present position of the Ceylon tea trade, from which, together with the striking figures which we published last month, our friends will be able to judge of the rapid growth of the trade in these teas, and of the high position which they have already attained in the estimation of the trade and of the tea-drinking public. From an experimental consignment of some 300 lb. in 1876, the imports have progressed by "leaps and bounds," and the import this season is expected to exceed 4,000,000 lb. and this rapid rate of increase bids fair to be maintained, for everywhere in the island, on the hills as well as in the lowcountry, fresh estates are being cleared and planted with tea, and old coffee estates which have ceased to be remunerative are having the coffee plants rooted up to make room for its more profitable new rival, and on the virgin soil of the island the plants not only produce teas of the highest quality, but are prolific to an unprecedented extent, the outturn per acre in some special cases being put down at no less than 1,500 lb. per acre. The plants, or "Jât," from which the crop is raised, differ in the various estates, and experiments are still going on to decide which kind is the most suitable. There are three main varieties of plants, viz., the Chinese, the Indian indigenous, and a hybrid obtained by crossing the two. To the variety of the plants and to the difference in soil and elevation the distinguishing characteristics of the product of the various estates are mainly due, as the method of manufacture by machinery is now almost universally adopted.

The teas from most of the estates are divided in a similar manner to Indian varieties, into the following grades :—

Orange Pekoe ...	the youngest and smallest leaves,
Broken Orange Pekoe ...	with golden orange tip.
Pekoe	young leaf, closely rolled, usually
Broken Pekoe... ...	well tipped.
Pekoe Souchong ...	the more mature leaves, care-
Broken Pekoe Souchong	fully made.
Souchong	mature leaves, more roughly
Broken Tea	made.
and sometimes	
Congou	eldest, roughest leaf.
Pekoe Fannings and Pekoe dust	names sufficiently descriptive.

The prices obtained for these various qualities vary greatly according to the characteristics of each particular parcel. The teas from the more celebrated estates, such as Rookwood, Loolecondura, Blackstone, Oonoongalla, &c., command very extreme rates, but an expert taster may often find teas of equal quality from less known estates at much lower prices than the crack marks are fetching.

As regards the value of Ceylons for blending purposes, we may say that, as a rule, they are matchless for fulness of body and richness of flavour, but they lack the strength and grip of many Indian varieties. These qualities render them more valuable for drinking unmixed than for blending, and those retailers who are doing the largest trade in Ceylon teas are selling them unmixed as a speciality, and find their superb quality thoroughly appreciated by the consumer. Many estates, indeed, put their tea up in air-tight leads, containing from 1 lb. upwards, thus preserving intact the quality and aroma, and these form very convenient packages for retailing.

FASHIONABLE NAMES.—Sericulture is now the fashionable name for silk culture; Dendriculture for tree growing; Fragariculture for the strawberry; Solanituberosiculture for the potato; and Znidroykstchantsthautzuidkleiniculture for we do not know what.—*Gardeners' Monthly.*

TEA DRIERS.

On next page will be found a letter addressed to us by Colonel Money, the well-known writer on Indian Tea, on Davidson & Co.'s improved Siroccos; another letter from Mr. Kinmond in reply to Messrs. W. H. Davies & Co.'s comparison of the Kinmond Drier and the Sirocco; and an extract from the *Indian Planters' Gazette* on improvements in Gibbs & Barry's machine, by which a ton weight of metal is saved. Mr. Owen wrote in favour of the latter, and we quoted full descriptions of it from a pamphlet we received from Mr. Horsfall, but we are not aware that any attempt has been made to import one into Ceylon. When the half-dozen improved driers which are being constructed for the Assam Company have been fully tried, we have no doubt reliable information will reach us as to the real merits of this adaptation of a corn-drier, as the American tea drier is of a fruit evaporator. Messrs. Davidson & Co., in their improved No. 3 Sirocco which is so highly spoken of, seems to have adopted the principle of the evaporator in the inclined addition to the machine which has added so much to is efficiency. Colonel Money, who, in the latest edition tf his book, gave the palm to Kinmond's Drier and spoke rather disparagingly of the Sirocco, is now strong in praise of the latter as finally improved. One of its great merits is, that, while comparatively cheap, no motive power is required to work it. We do not understand Colonel Money as offering any objection to Kinmond's machine except on the ground which struck us, the high cost. But this cost has been materially reduced. Mr. Kinmond claims for his machine superior economy in fuel and this is a question which only practical planters can settle. Our own impression is that *all* makers of drying machines, promise more work and less expenditure of fuel than can practically be realized. Mr. Kinmond points out that four Siroccos would take up much room in a tea house. But, if they were spread over the floor area, the warm air escaping from them would be, in wet cold weather, a valuable aid to the withering process. A practical planter's remark to us was, that, if Kinmond's machine got out of order, a planter who had it only in his store would come to a stand-still, while a factory with several Siroccos could go on working if one, or even two, of the machines broke down. He also said he found no difficulty in burning green wood in the stove of the Sirocco. We know that No. 3 style, does very good work, Sirocco, old and we trust ere long to be able to have equally favourable experience of the machines with the inclined funnel added. May we ask those who have Kinmond's machine in use to favour us with their matured experience of its working, all Mr. Kinmond's directions being observed? Our feeling at present is that Kinmond's Drier is only suitable for pretty large "concerns" and that even in such cases a good combination would be two Siroccos to each Kinmond, or perhaps, in the case of 600 to 1,000 acre estates, eight or twelve Siroccos to two or four Kinmonds. But the experience of the great Assam Company with the new Gibbs & Barry Driers will be of value to the owners of large factories in Ceylon. Where that machine is used to partially fire the tea, we should think Siroccos would be useful for "pucka battying" or finishing off. The three machines we have been noticing may probably be described as "good, better, best;" but which is best, readers with the ample information placed before them must judge for themselves. For combined *cheapness* and efficiency, the leaning at present will probably be in favour of the improved Sirocco.

IMPROVEMENTS AND ALTERATIONS IN THE SIROCCO TEA DRYER.

East India Club, St. James' Square, London, S. W.
December 12th, 1884.

SIR,—Many tea gardens in Ceylon are just now at the stage when it is all important for the owners to decide which of the various machines, offered for the different processes in manufacture, is the best.

As you possibly know, tea, and all appertaining to it, has been my study for many years, and in the fourth edition of my book* I discussed at length the many tea machines. Among them I noticed the "Sirocco Tea Dryer," but not very favourably, for I there say "when it came out it was, I think, the best machine (dryer) going. I doubt much that being the case now." But quite lately at the inventor's (Mr. Davidson's) request, I have seen the great alterations made by him in the Sirocco, and the result is that I am sure no planter, in want of a dryer, should decide on his choice, until he has heard and enquired about the new Sirocco. Mr. Davidson has during the last month, been exhibiting it at 60 Gracechurch St., and, that, I am not singular in my estimation of its merits is proved by the fact that he has sold upwards of sixty of the new machines to firms and individuals, well conversant with the necessities for a dryer!

The old Sirecces had more than one fault.

1. Unless great care was exercised burnt tea was sometimes the result. 2. The quantity turned out was small. 3. The tea was not dried entirely by hot air, but partly by the heat given out by the hot iron. 4. The iron of the machine, exposed to the greatest heat, buckled out of position and burnt away. 5. The employment of an air chimney had drawbacks, it carried off much of the hot air, not only out of the machine but also out of the factory, and the chimney passing up through the roof was objectionable. Each and all of the above faults have been done away with in the new machine, and as far as I can judge, it possesses all the necessary conditions for turning out, at a strictly moderate cost, high class teas in considerable quantities, fired to the exact degree necessary.

It is not easy to describe a machine without diagrams, still I will make the attempt. In outward form it resembles the capital letter T with the right projection from the top of the vertical stem omitted. The stove is at base of the vertical stem. The tea is dried at top of the left horizontal projection by hot air, which ascends the said vertical stem, and then runs along under two lines of trays to the end of the said horizontal projection. The trays are eight in number. The feeding side is at top of the vertical stem. When all charged and placed, there are four above and four below. The upper tier is pushed forward one step when each tray with new roll is introduced at the feeding end into position No. 1, and on arrival at the other end into position No 4, the further introduction of another such tray pushes No. 4 out, which is then transferred down into the lower slide, and pushed into position No. 5. Thus, each tray makes one journey forward and back again, along the horizontal flue represented by the left top projection of the said capital letter T. When it has made this journey, it is of course once more at the feeding end, but in position No. 8.

At each extemity of the said horizontal flue, the metal slides or rails, on which the trays run, project 2½ feet beyond the flue. This at the farther end enables the boy who works there to pull out the tray with half-fired tea on it, re-spread it and introduce it conveniently into the lower slide. At the feeding end it serves two purposes. It allows the tray to be pulled out and the tea examined. As a rule when it (the tray) arrives at this last, or 8th position, the tea on it is sufficiently fired, But if not so, it is again re-spread and put back again in No. 8 position until it *is* done. The other purpose and a most important one constituting one of the great advantages of this new type of Sirocco is as follows:—

When the tray with the tea finished or nearly so has arrived at position No. 8 and is ready to take out, it follows of course No. 1 is empty. The tray to fill that position with new wet roll on it is first placed there and after this is done the lower tray in position No. 8 is pulled out to be examined as described. The current of hot air which ascends the vertical stem and is then hotter than at any time after (that is to say hotter then, than later when it runs along under the trays) touches nothing (the space below being now clear of tray No. 8) until it impinges on the said wet roll on the tray in position No. 1. It does this at a temperature of 350°, and consequently immediately arrests further fermentation. All planters know that stopping fermentation at the right time, and suddenly is one of the main points in Tea Manufacture, and one of the great virtues in the new type of Sireccos is its excellence in that respect.

The trays are worked or pushed along by one man at the feeding, and one boy at the farther end. The boy of course has only to transfer each tray after it has arrived in position No. 4 to position No. 5 in the lower slide.

I have thus detailed at some length the way the trays are worked, but I should trespass too much on your space, did I dwell as fully on all the other parts of the machine, and its workings. What remains I must state hereafter. In the machine I am describing hot air alone is the agent for firing the Tea. By very ingenious contrivances the following is attained:—

1. Whether coal or wood is used the said hot air is quite free from the smoke or fumes of the fuel. 2. Whereas in the old Sirocco, the sides of the machine gave out and wasted much heat, in this new type the sides are comparatively cool. The hand can be placed on any part without inconvenience. 3. The heat which in the old type *was* given out and lost from the sides of the machine is now trapped in chambers formed by the present double sides, and is absorbed by air currents admitted at the base of the said chambers; and the hot air thus produced forms a continual ascending current and is admitted into the upper part or the vertical stem. Thus, instead of being wasted this spare heat is used *as an addition* to the main hot air current for drying the tea. 4. Whereas again in the old Sirocco the ascending currents of hot air were often not equal in temperature and thus the tea on one part of the tray might be overfired while other parts were not done enough; by an ingenious arrangement of "hopper shoots" in the vertical stem, the possibility of this is now quite avoided. The said ascending currents as they leave the vicinity of the stove are still often not equal in temperature, but before reaching the tea they are all *forced* to mingle together and become uniform. 5 So much of the hot air current as passes through the wet roll on tray in position No. 1, and is consequently charged with much moisture is not used again at all. In other words, the moisture from that tray, is not, as with some dryers, carried on to another.

6. In no place does the hot air current pass through more than two trays, and a great point is that in each position it passes through the *drier* tray first.

7. After passing through two trays it goes upwards into the Factory, at a temperature of 120°, and is available to help in leaf withering.

8. The chimney is attached by a flue and bend to the base of the machine, and may be carried up the

* Tea Cultivation and Manufacture by Lieut.-Col. Money 4th Edition. Sold at *Observer* Office, Colombo.

outside of the Factory wall. With the smoke escapes, of course some heat, but only about one fifth of what is generated by the fuel, which says not a little for the ingenious construction of the stove, and air heating chambers.

9. No motive power is required. The force made use of, and it is ample, is a natural and constant one, depending on the simple law that hot air ascends, and causes a partial vacuum. There is thus no expenditure for motive power.

10. The stove and part of the vertical stem should be sunk in the ground to such a depth as to allow the top of the horizontal flue, or hot air chamber, (the left projection of the letter T,) to be 3½ feet above the floor. The tea can then in the upper range of trays be conveniently examined at all times, and its progressive rate of drying seen to.

11. The tea cannot so readily burn now. First the heat is uniform as explained in No. 4, secondly the lower tray is now 6 feet above the stove, instead of 3 feet as formerly.

12. The important alterations effected, make it impossible for the iron of the machine to burn as it did in the old type.

13. The temperature taken at top of the chimney is about 250° as against 350° kept back, and the *volume* escaping is small as compared with what is retained and utilized.

14. The fine tea or "goorie," which falls through the sieves when in positions Nos. 5, 6 and 7, lies all day at the bottom of the horizontal flue, and is collected when the work is finished. It receives no injury by remaining there, because the outer and lower face of the iron, on which it lies, is exposed to the outer air, and secondly heat from hot air strikes very feebly downwards.

The old form of siroccos, if there happen to be any in Ceylon, can now be converted into the new type at a cost of £23 for the parts necessary. These being obtained, any blacksmith can effect the conversion. The old types were No. 1 burning coal or wood, and No. 2 burning coke or charcoal only,

The new Machines now making are Nos. 3, 4 and 5, thus:—

	Maunds of Fuel required for a day of 10 hours.	Maunds Tea in a day of 10 hours.	Prices f. o. b. at Liverpool or Glasgow. £.
No. 3*	Coal 5 to 6, or Wood 10 to 12	9 to 10	90
No. 4†	Coke or Charcoal 4 to 5	9 to 10	55
No. 5†	Coke or Charcoal 8 to 10	15 to 18	95

*Current hot air only. All the foregoing description applies to this machine.

†Products of combustion of good coke or charcoal mixed with air. No chimney. Shortly described below.

No. 4 differs from No. 3 only as regards the stove or air-heating portion, and of course requires no chimney.

No. 5 is similar in principle to No. 4 but twice as large. It has a much larger stove which practically works two No. 4 dryers placed side by side.

The stove of No. 3 is all iron. The stoves of Nos. 4 and 5 are brick work with the necessary iron fittings.

The above descriptions would not be practically complete without my opinion as to which is the best machine. I will give it in very few words.

Those who have a No. 1 Sirocco should alter it to the No. 3 form, and those who have a No, 2 should make it like to a No. 4. No need whatever for such to get new machines.

Because, I think, pure hot air, as a drying agent, very superior to the products of coke combustion, and possibly superior, certainly equal to the products of charcoal combustion, I advise new purchasers to confine themselves to the No. 3 machines only.

I see no real advantage in one No. 5 over two No. 4 beyond £15 saved in the cost.

One word in conclusion as to the prices of Siroccos. Tea at its present market rates, can't afford expensive machinery. As regards dryers, Mr. Davidson has awoke to this fact. His prices for the new siroccos *are* certainly low. He being his own manufacturer, has not to add makers' profits, and thus, perhaps, he can afford to sell lower than others.

I have lately sent two articles to the *Tea Gazette* published in Calcutta, anent these new siroccos. The descriptions are there more in detail than I give here, for I feared you would deny the space. They can be referred to by enquirers to supplement this letter.

EDWARD MONEY.

TEA DRYERS.

Sunnycroft, Leamington, Dec. 5th. 1884.

SIR,—In the *Observer* of November 8th appears a letter from Messrs. W. H. Davies, & Co., under the above heading in which they give what they call a comparative statement of the capabilities and prices of Kinmond's dryer Messrs., Gibbs & Barry's and the "Sirocco." The Gibbs & Barry requires coke or charcoal fuel and need not therefore enter into the comparison which I now give as under :—

	Outturn per hour of perfectly dried tea.	Cost f. o. b. England.
Kinmond's No. 3 dryer ...	3 maunds	£250
,, No. 2 dryer ...	2 ,,	£178

Note.—The above dries one maund tea with the consumption of *less* than ½ maund *ordinary* wood-fuel.

The No. 3 "Sirocco"...	1 maund	£ 90

Note.—The above (accordiog to Mr. Davidson's Circular) dries 10 maunds tea with the the consumption of 12 maunds *dry* wood.

That is, the "Sirocco" requires more than *double* the fuel required by Kinmond's Dryer. The "Sirocco" owing to its small furnace requires *dry* fuel. Kinmond's with its large furnace may be used with green or any kind of fuel.

One other fact will hardly escape the eyes of planters when making the comparison. Kinmond's latest improved dryers have been working for the last two seasons at the rates stated above. The "Sirocco" has been working during the same time doing exactly *half* the work which now it is asserted it can do. Query? *Where* is there a No. 3 "Sirocco" now working at the rate of one maund of dry tea per hour.

Thanking you in anticipation for inserting the above in the *Observer*. yours faithfully,

J. C. KINMOND.

P.S.—Messrs. Davies & Co. omitted to state the fact that a No. 3 "Sirocco" occupies more space than my largest size dryer and that three No. 3 "Siroccos" would fill a good size tea house.

THE GIBBS & BARRY NEW TEA DRYER is thus described in the London Tea letter of the *Indian Planting Gazette* :—

I went out to Chingford, a few days back, to inspect the Gibbs and Barry new type of Dryer, and it is certainly in many respects a grat improvement on the original type. Thus, a ton weight of metal has been completely done away with in the construction, by changing the manner of supporting the cylinder. The massive girders are no longer necessary as the support is arranged for by a new appliance attached to both ends, these appliances being themselves supported on brick pillars. This in no way weakens the machine, but considerably lessens its cost and of course effects a great saving in weight and freight. The revolution of the cylinder is no longer effected by friction-gear but by mill-gearing ("cog-wheels") which will be found both more durable and more regular in action. The means of raising the end to the desired angle is now much simplified and improved, by a complete change in the gear employed for this purpose. By means of an additional air conduit from the fan, the dust can be helped forward, but without a diagram this novelty—simple enough in itself—would be difficult to explain, and an attempt to do so would probably end in confusing the reader. Mr.

Gibbs feels convinced that the length of the cylinder, might be increased to the full length now in use in his largest corn-dryers, viz., 36 feet, to the great increase in the outturn. As the present cylinders are divided—facility in transport—in the centre, the additional length can be obtained by simply ordering, the extra lengths to be sent out, and these can be added in the centre of the present cylinders, as the screw-rivet holes will be found to tally in all the lengths. Of course this cannot be effected with the old girder-supported cylinders but with the new system it merely requires one of the end supporting columns to be moved, as the supports are strong enough to bear the extra strain. As the fan at present moves so slowly, the extra speed and volume of hot air can be obtained from the present fans, with a very slight increase in the motive power. It will thus be evident how great a stride has been made by doing away with the girder-supports, as not only does it effect a saving in first cost, in freight, in trouble in erection, but it also allows of the machine being increased in working-power, as the need arises, at a very trifling additional cost, and with but little derangement of the original site. It only remains for me to add, that the first six of the new type Driers are already being shipped to the Assam Co., and Messrs. Gibbs and Barry anticipate a still greater success from the new than they have already achieved with their original machine. There is a rumour of another new Dryer being about to make its appearance, but as it is not yet patented, I am not at liberty to enter into any details. It is a pity some of the talent now being devoted to other matters is not given to sorting by machinery.

COFFEE AND TEA PLANTING ON THE HILLS OF CEYLON.

FINE WEATHER FOR TEA, COFFEE AND CINCHONAS, AND ALL FLOURISHING—CINCHONA GROVES.

LINDULA, Jan. 1st, 1885.

The rainfall on the 30th was only 0·42 of an inch and none having fallen on the 31st, the total for the month was 6·83, or 0·17 short of the round number estimated. Between 3 and 6 p. m. on the 31st all the meteorological indications, however, betokened an excess of the estimate instead of a deficiency. The sky became black with lowering clouds and the cold breeze which generally heralds the deposition of rain made itself felt. The tea-pickers were hurrying to the withering-house with their baskets, lest the leaf should be injured and the withering hindered by the rain which seemed so imminent. But, from causes so difficult to understand as to seem capricious, the clouds finally lifted and dispersed and as the sun was setting on one side of a clear sky, a brilliant, silvery full moon appeared over the top of the Nuwara Eliya ranges on the other. And so the gathering of 3,205 lb. of green leaf was housed and "sheived" unweighted by moisture, while the weather last night and today has been most favourable to the withering process. As morning dawned the mountains stood out clearly defined and the sun's heat as the day advanced was unmodified by even a fleck of cloud. The abundant young wood of the coffee is running a race of flushing with the tea and the remark was made: "If this weather continues, there will be a fine blossom out by the end of this month." The promise of blossom will probably be fulfilled and in pre-fungus days we should be justified in anticipating a proportionate setting of crop, the trees looking so well as they do. But with all our past experience, we can only "hope for the best." There is a very general opinion, however, that the fungus has done its worst on coffee, and that as it first appeared in the east of Uva, so it has commenced the waning process in the same districts. About the increasing out-turn of tea, on the other hand, the grounds for confidence are very strong. On the place whence I write our regret is that for the sake of the difference between £90 and £130 we did not at once invest as we now must in a Jackson's "Excelsior" roller. The "Universal" has been going night and day and is even now at work, in order to keep pace with the leaf. It rolls beautifully, but whatever it may be capable of at a lower elevation and a hotter climate, up here it falls far short of the quantity specified in the maker's prospectus. Its capability was said to be the rolling of 60 lb. of withered green leaf every 15 minutes. That would be 240 lb. or 3 maunds per hour. In actual working (motive power, a Walker & Co.'s water wheel), it does not accomplish quite half this quantity. Worked at this rate, "the roll" comes out beautifully finished (50 lb. every 25 or 30 minutes), and *quite cool*. Much importance is attached by tea makers to this condition, and we have been told (we cannot speak from personal observation), that the great defect in Kinmond's roller is the temperature to which it sends up the leaf it operates on. This is a defect, which slower working would probably cure?

While on the subject of tea machinery, I may repeat that Jackson's sifter, like his roller, does excellent work, but I am only expressing a general opinion when I say that for a machine composed mainly of timber, the price charged seems excessive.

In justification of my anticipations of a very large tea traffic for the railway, I need only adduce the beginnings of tea cultivation which were apparent in the course of my round this morning from Abbotsford *via* Inverness and Dessford. Tea in varying stages of growth, is everywhere. On Inverness "new clearing" it is difficult to say, which has made the more rapid progress, tea or the splendid cinchonas, which at eighteen months old are well-grown trees. But the most cheering and gratifying sight to me was the regular success and luxuriant growth of tea on the expanses of Esdaile, where previously cinchona had proved such a heart-breaking disappointment. My only grief in looking at it was that the good and accomplished and true-hearted gentleman, Edward Heelis, had not been spared to see the turn in his own family fortunes, in the fortunes of Dimbula and those of Ceylon which tea is certainly destined to accomplish.

To return to the Lorne road and the forests of cinchonas on Avoca, and especially Dambugastalawa: The doctrine of "the survival of the fittest" is here strikingly illustrated, for the cinchonas (succirubra, officinalis and hybrids equally flourishing) which were planted amongst the coffee as a subsidiary cultivation, have asserted the paramount place, killing out the coffee trees, which I can remember as of such brilliant promise, and which in the infant stage of the fever trees afforded them shelter. If cinchona pays anywhere it must be on such places as Lorne, Avoca, Dambagastalawa and Mattakelle. But the fate which has overtaken sugar and coffee has not spared quinine bark and the consumer has benefitted at the expense of the producer. But low prices for sugar and coffee have always led to a reaction, in consequence of largely increased consumption, and the same process, though not perhaps in the same degree, may be anticipated in the case of cinchona, there being wide room for the increased use of the febrifuge and tonic alkaloids, not only in the treatment of human beings but in veterinary surgery. Other uses for the bark and its extracts, too, will be discovered, by the brewer, the tanner, the dyer, &c. But after the lessons of the past, Ceylon cinchona growers must certainly prefer to burn or, better, bury the small twigs, rather than send their bark to the London market to sell at from 1d to 4d per lb. In the cases of cacao and tea, we must, we suppose, be prepared for the same process of over-production and its effects, which have so adversely affected wheat, sugar and coffee. In such a case Ceylon seems to possess ad-

vantages, in the case of tea at least, which ought to enable us to hold our own in the contest of competition. We must, however, study economy to the utmost and the one great means towards this object is the extension of facilities of communication.

CEYLON UPCOUNTRY PLANTING REPORT.

HOLIDAYS OVER—TEA, TEA EVERYWHERE—WHERE IS THERE BAD TEA IN CEYLON ?—MARIAWATTE—PRICE OF OLD LAND RISING—TEA COMPANIES—THE KOTMALE VALLEY TO BE BOUGHT UP FOR TEA—TEA MACHINERY —CACAO, THE RED-ANT AND HELOPELTIS—TEA F. O. B. FOR 25 CENTS PER LB.!—COFFEE AND BLACK-BUG.

5th January 1885.

Now that the holidays are over, and people are again settling down to work, let us hope that with 1884 the period of unremunerative labour will have closed in Ceylon, and that the reward for honest endeavour will be different in the coming year from what it has been for some time past. Of late we have too often reaped disappointment; have had worry and anxiety given us for the sweat of our face; have planted and cultivated with fear and trembling—"thorns and thistles" alas! too frequently the guerdon for experience and watchfulness—till there has crept over us the feeling of blank despair, and the unnatural belief that the future would be as the past, and that misfortunes would dog us to the end. Now-a-days we plant with no sure expectation that the product of our hopes will grow: at least that is the sort of under current—born of bitter experience—which is present in the mind, although not often put into words.

Tea, however, is the great exception to this rule; and the swing of the pendulum has been so marked and strong, that over all kinds of waste lands and abandoned estates there is now a glamour, and the mind dwells on a future fraught with wealth, ease and contentment—a pleasing contrast to the past with its deep depression, heavy losses and sad trials.

You travel over the country with a sanguine friend. The light in his face and the cheerfulness of his tone is as refreshing as a cool morning breeze, and, like the genii who could turn earth into gold, he puts wealth into land lately worth only an old song, as he scans the lantana-covered ground, and with a magnificent sweep of his hand says: "All suitable for tea."

And who can gainsay this? Where Mr. Editor, can we see bad tea?—an honest enquiry, no libel case snare in this. A friend of mine has been often urging me to get for him the name of the district and estate in Ceylon where this is to be seen. He will make a pilgrimage to it, drink in its lessons and perhaps congratulate its owner on his unique possession. I don't know that he will go the length of wanting to buy it, still if such an estate is in existence here, why do we not hear of it, so that we may go and see it? The "all suitable-for-tea" man has a decided advantage over us until we can point to such a place. The scorner may sit in his seat, prate about a possible disappointment, try to be wise above what is written, and those away from the whirl may consider his scoffings and warnings not without value; but what are we to do with the sanguine man until we can lay our hands on the bad tea, and "stick him" with that?

When Mariawatte was being planted, one who had to do with it was most emphatic in his opinion that it would grow nothing—a mere sandhole—and now? Well everything is changed.

From the sea level to the tops of the highest mountain ranges there comes from the sanguine man the one cry: "All suitable for tea." We are sadly in need of having the bad tea trotted out, that is if there is any. Supposing the sanguine man to be right even to a very limited extent, it is a bad look-out for "the boom" although the prospect for Ceylon itself will thereby be much improved. With such large extents of land in which tea may be expected to grow, it will want a very big rush before prices go very high.

It is very marked how a good tea estate raises the value of land all round. I have heard that R100 an acre has been refused for an abandoned property —"suitable for tea"—in the vicinity of Gampola, which some time ago might have been bought very much cheaper. A Chetty in that same quarter who had land to sell, answered an inquiry as to price by saying that he asked all gentlemen R150 an acre but would consider an offer.

The Tea Companies which one hears of in the course of formation are getting very numerous. Friends write you from home that they have knocked up against some old Ceylon man, and in asking what he is doing get the invariable answer: "Trying to start a Tea Company."

I hear that a lot of Indian men—capital (so the rumour) says, unlimited—have their eye on buying up the whole Kotmale valley, and have already purchased some of the places.

Tea Machinery is becoming so important a matter here, that inventors are keeping their eyes open as regards their new rivals. It is rumoured that one of our planters whose roller has given satisfaction has been called on by one of the largest makers to give an account of himself in regard to an alleged infringement of patent. I sincerely trust that the planter may be able to establish his right to his machine, and reap some reward for his expenditure of time and brains. Ceylon men have always been very inventive, and one cannot but wish, that, when they hit upon something which is useful to the public, it also may prove of value to themselves. One of the largest "Sirocos," and also the newest kind is about to be erected at Imboolpitia, an estate which looks well, and is doing well. An idea of the size of this dryer may be gathered from the fact that a hole seven feet deep had to be dug for the foundation. It is on a new principle, I understand, or at least new in the field of tea-drying never before having been thus applied.

The promise on cacao is said to be very good, and where last year things were looking queer, now there is a marked change for the better. The red-ant—of the bull-dog type—is proving a complete cure for the *Helopeltis*. Where colonies of these insects have been established there the pods remain free from the pest, and those who know the value of this cure, do what they can to encourage the red-ant to take up its abode among the cacao.

At what cost tea can be put *f.o.b.* is interesting to most people. The best rate I have heard for a year's working was 28½ cents a lb; in another case for a portion of a year the price was 25 cents. These doubtless are exceptionally good, but as far as I know they can be relied on.

As to coffee, those who don't know what black bug is, keep up a kind of cheery tone; but those who do, are inclined to draw the curtain and retire.

PEPPERCORN.

A COMPLIMENT TO THE *T. A.*—A well-known planter upcountry has been good enough to report to us the following, which we take as a compliment to the *T. A.* as conveying the opinion of a chemist of high standing upon it:— "Amongst other papers &c. a chemist of high standing at home sent me, through a mutual friend, your *T. A.* for June last."

POSITION OF THE TEA TRADE.

From the *Home & Colonial Mail* we learn that at a meeting at Messrs. Thompson & Co.'s office it was settled that small breaks of tea, which are defined as "all breaks under 8 chests or half chests and 20 boxes," should be passed over at the time of sale of the large breaks and disposed of at the close of the day. This arrangement is made in favour of the large buyers, but the smaller breaks will probably not suffer. We do not know what the experience of other exporters of tea may have been, but in our own case we have found that breaks of about 2,000 lb. of tea have sold better than invoices of 6,000 lb.

The same paper reproduces an elaborate article from the *Produce Markets Review*, showing how the once important and steadily conducted China Tea Trade has fallen from its high estate, the old and well known China firms, who traded on their own capital, having retired from competition with persons more speculative if not more reckless, who operated largely on borrowed capital. Such a mode of doing business always, of course, brings its own penalty in its train and the China tea trade, as conducted in recent years has proved no exception to the rule. Over-exports, especially of low quality teas, led to unremunerative prices, the evil, as far as China teas were concerned being aggravated by the increased import into Britain of the superior quality teas of India, Ceylon and Java. The final result has been a considerable reduction in the supplies of tea from China, the hiatus thus created and the gradual increase of consumption being fully met by the production of tea in India, Ceylon, Java and other sources of supply never dreamt of in the palmy days when China had a practical monopoly of the fragrant leaf. It is true, that our most recent advices from India report a deficiency of four millions of pounds in the estimate for the year of sixty-six millions. But this is a mere temporary decrease which will scarcely affect the position of the trade. The effects of the Franco-Chinese war, which is, apparently to be carried on to the bitter end, may not be so great as some persons think, but that a considerable effect it should have in limiting supplies is inevitable. But we believe that a far greater, and to China, more adverse effects will be produced by the rapidly-growing taste for the stronger and purer teas which India, Ceylon and other places are, under European superintendence providing to meet the wants of consumers. The sharp correction administered to the reckless conduct of the China tea trade, cannot but react favourably on India, Ceylon and Java, and in discussing the probabilities of increased consumption we ought not to leave out of view the material effect likely to be produced by the unprecedentedly low price of sugar. Tea, coffee, cacao and all like beverages ought to profit by the, to sugar planters, unfortunate state of the sugar market.

THE STATE OF THE TEA TRADE.

The present condition of the China tea trade is thus described in the *Produce Markets Review*. Those who know the unsatisfactory position of the trade, and the uncertainty and distrust prevailing will not consider that the views there expressed are exaggerated or ill-founded. The wonder is that, in face of the remarkable condition of things now existing, the failures and embarassments have not been more numerous. Apart from other circumstances tending to affect adversely the profitable import and sale of China teas, the rapid growth of the cultivation in India, Java, and Ceylon must have given a serious blow to the China trade, and narrowed the prospect of its revival under more prosperous conditions. The outlook is anything but a hopeful one, and we doubt if the "old China houses," to which our contemporary refers, will find the opportunity to take up the trade a very advantageous one:—

"Steam navigation on the Yangtse, the cutting of the Suez Canal, and other quicker means of conveyance, coupled with the extension of the telegraph to the East, the opening of Japan, the vast increase of tea cultivation in India, Java, and recently in Ceylon, are all causes which have for some years past been slowly but completely revolutionizing the importing trade. The changes that have taken place have ended in the more or less complete withdrawal, from a trade which they no longer found profitable, of the firms of merchants formerly so well-known in connection with the export of China teas. A class of merchants took their place, who were dependent not only upon their own capital, though that was often considerable, but on large credits and advances from bankers and others in China and here. Without the resources of the old firms, the extent of their business was copied, and once a trade of the sort has been entered upon, it has to be carried on, even when transactions show a loss, until a point is reached when monetary facilities are withdrawn, when a collapse ensues. Of course, such operations in the ordinary course of business might, and often do, lead to the attainment of great fortunes, and even the wealthiest importing firms must require facilities now and again. It is thus a question of degree, but the peculiarity of the China trade of late years is, that it has been, to a greater extent than is usual, carried on with money belonging to others than the importers, and at a time when, owing to the immense increase in the production, and to the comparatively stationary state of the demand a gradual but ultimately heavy fall in prices was a matter of certainty. The natural result of such a remarkable condition of things has been that the China tea trade has for years past been in a very unsound position, and that the sudden rise of apparently great businesses has too often been succeeded by their equally rapid disappearance. This year the position has been further complicated by the singular, and as yet incompletely explained, decline in the value of all produce, which of course affected tea, and to such an extent that a few months ago it seemed impossible that the market could fall further. Nevertheless, it has recently been followed by what was nothing less than a panic, which can now be the better spoken of, as there is no risk of adding to a pressure that has passed away.

"Of late years the tea trade, from the extent of advances upon bills of lading to importers and upon warrants to merchants, dealers, and brokers, and in many other ways, has partaken a good deal of the pawnbroking character. A short time back some exceedingly unsound, if not fraudulent, trading was brought to light, and led to an immediate search through securities by bankers and others, and to a general and sharp curtailment of credits and advances. This was accompanied by a very rapid rise in the Bank rate, which tended to increase the pressure. As the tea market had previously fallen heavily, the margin was found by those who had advanced on tea in many cases to be insufficient, and there was, of course, a further collapse in prices, and a fresh fall, in some cases of 3d. and 4d. per lb., took place within a few weeks. This fall, however, was of a most irregular and indiscriminating character, for while common sorts did not suffer much, the better kinds were in some cases forced off at far lower prices. The panic in the tea market did not, however, last very long, and prices have since, as it were, been sorted out more in proportion to intrinsic values. In some cases parcels bought during the severest depression a few weeks back can hardly be matched within 2d. or 3d. per lb. of the prices then given, and in some few exceptional cases the difference is even double this. Within a couple of months, therefore, some sorts of Congou have fallen many pence per lb., and have since risen to almost the same extent. Such violent fluctuations are unprecedented, especially at a time when the general position of tea is really strong. Prices, on the whole, except for a short time just recently, have never been so low as they are now. On the other hand, the exports from China have fallen off heavily; the stock in London on November 30th, allowing for arrivals not included in the return, was 10,000,000lb. less than last year; the home consumption, including coastwise deliveries, for the seven months, was 4,600,000lb.

greater; and the exports were 2,000,000lb. heavier. Against these very strong figures a considerable increase in the supplies from India and Ceylon may be expected for the current season, but, on the other hand, it appears to be generally thought that unless great changes take place in the market, many of the recent shippers of tea from China will be forced to discontinue their operations. Their own capital must be much reduced, if all that is currently rumoured as to the heavy losses on tea this season be correct; and the banks and others who have financed hitherto and who have been so heavily hit this year, will not so readily afford the facilities that have been recently customary. It will be therefore useless for those who have been losing hitherto, but still have something left, to attempt to take up the business of those who have given up the trade, and to attempt gigantic operations on borrowed money, so that the extent of turn-over should reduce the proportionate expenses, and thus lead to a profit, instead of a loss. Under these circumstances, with the low prices here, the strong statistical position, and the probable diminution of competition by the banks and others with legitimate mercantile business—for that is one way of looking at recent events—with all these causes at work, it is thought by no means improbable that some of the old China houses will again take up the trade they have recently abandoned to more enterprizing or more reckless rivals. If so, it will certainly be satisfactory to see a certain element of solidity restored to the tea trade, which has been sadly wanted of late.

"The home trade also has been in a most unsatisfactory state, for, owing to the fall in prices, brokers and dealers alike have been unprosperous, and, as has been done in China, the bolder or more reckless members have taken to financing and pawning, in the endeavour to make up for lost profit by increasing the turn-over. This also, it is to be expected, will receive a severe check, through recent revelations. In the meantime there is a general feeling of mistrust, which is no doubt embodied in the recent statements in the Press which have created so much annoyance. In details those statements were erroneous, but their general tendency fairly enough sums up the uneasiness prevalent in the produce markets of late. Among others the wholesale tea dealers have their own special subject for disquiet in the deposit question. Unless a broker intervene and give credit for a consideration, as is very commonly done in these new-fangled days, it is still the remarkable custom in the tea trade to give credit to the *seller*, and to pay a deposit amounting to about fifty per cent of the value of the entire parcel, after the weight-notes are given to the buyer. Sometimes this deposit is paid to the original selling broker through an intermediate broker, and in case of the latter's failure to hand over the money received, it appears very doubtful whether the dealer could not be compelled to pay over again. In the ordinary way, when deposit is paid to the original broker, another class of risk occurs. In cases of advance, the banker, under the Factors' Acts, has a prior lien which comes before all others, and it is at present exceedingly doubtful whether, in case of the failure of a merchant or a broker who had pawned warrants, the banker could not call upon the dealer, not only to pay the deposit over again, but to pay the full sum which the banker may have advanced, which may be very much more than the true value of the tea. This subject is now under discussion, but enough has been said to show that the importing and distributing tea trades have of late been in a very unsatisfactory position.—*Home and Colonial Mail.*

TEA IN NATAL.—It is reported from Natal that a tea estate near Durban is doing remarkably well, and that the proprietor, Mr Hulett, counts on getting 800 lb. of tea per acre, at a cost of 6d a lb.—*Pall Mall Gazette.*

THE MANUFACTURE OF PAPER IN CHINA.—The *China Overland Trade Report* states.—Extensive paper mills have been erected on the Yangtsze-poo Road, which possess the best and newest machinery, and as unlimited supplies of old rags are obtainable in China and a good market for the paper secured, there is every prospect of the venture proving a great success. It is not impossible that a similar undertaking may before very long be launched in Hongkong.

SUGAR IN JAVA.—The *Java Bode* of the 10th December, affirms that in the opinion of many people at Batavia there is every prospect of the sugar crisis, disastrous as it is, now becoming worse next year. As a relief measure to planters in the present hard times, the Governor-General has passed an ordinance, to be in force for one year, enabling them to hypothecate their growing crops. It is, however, generally held that to save the planters from ruin, the native population dependent on the sugar estates from impoverishment, and the estates themselves, when sold off for debt, from passing into the hands of Chinese and other foreign Orientals, this enactment should be followed by others securing sugar growers relief or exemption from taxation, and lowering railway freight rate. The long established firm of Dorrepaal & Co., at Samarang, which does an extensive planting business, has been relieved of difficulties arising out of the sugar crisis by raising money amounting to several millions of guilders, thus enabling it to carry on operations for the present.

TEA IN CEYLON.—A Colombo correspondent of the *Indian Planters' Gazette*, writes:—Scarce eighteen months ago to give the planting community partial relief, a couple of merchant brokers endeavoured to hold weekly sales of tea by auction in Colombo. The sales were so badly attended, and the bids so poor, that the plan was dropped after a month's trial. Now it is hard to get material enough for local tea sales, though bidders are plentiful and the local consumption is not met. Ship, ship, is the order of the day, and the effect of so doing regardless of the make or quantity in a break, is just beginning to show in the recent account sales. The facility for shipping in Ceylon is very great, and may be judged from the fact that one estate 85 miles by rail from Colombo, put its tea on board on the 8th day from the date of picking! It was done not as an experiment, but seriously to make up a proper break for despatch by a certain date. Colombo presents little or no signs of a rising industry like tea, save carts loaded with shooks for tea boxes, going to the railway station for despatch up-country, and carts returning from the station to the wharf laden with tea chests. That there are millions of pounds of uncut timber in Ceylon none can doubt, but strange to say the local demand for ordinary wood cannot be met fast enough and a great deal of it is being imported from Burmah chiefly. The timber is sawn in several mills in Colombo into suitable dimensions. Luckily for the Ceylon planters excellent Sinhalese carpenters are plentiful, and are now obtainable on low pay, though at one time they were the most expensive set of artizans to employ; b sides, being possessed of property and means, they could not be induced to work under a rupee to two-and-a-half rupees per diem! They gave, and still give much annoyance, and any attempt to punish makes them decamp to their villages in the far interior. It has been found the best in the end to give them work on contract, a headman amongst them being responsible for the rice supplied and sums advanced while the work is in progress. One enterprizing planter who has not been a gainer by the coffee enterprize has hit upon a happy idea. He leaves Ceylon selling all his lands there, for Ireland and taking with him large orders for tea shooks, which he means to carry out by sawing Canadian timber in Ireland, and shipping it to poor Ceylon! The scheme promises to be a success and has the substantial support of no less than five of the most successful tea planters. If the Ceylon Government was an enterprizing one, it might make up for the loss of Colonial rupees by supplying the Russians with tea. Odessa is no distance to ship to. [But a merchant long settled in Russia is said after visiting Ceylon, to have decided that Ceylon tea was not suitable for the Russian market.—ED.]

To the Editor of the "Ceylon Observer."

IRRIGATION BY MEANS OF HAND FIRE-ENGINES AND RENOVATION BY MEANS OF CRUSHED LIMESTONE, IN THE CULTURE OF COFFEE, TEA, &c. RECOMMENDED.

London, 28th Nov. 1884.

SIR,—As exception is generally taken to advice upon planting matters, tendered from England, to those engaged therein in the tropics, such being considered the wild suggestion of mere theorists, in inditing the following remarks, I may premise that my planting experience covers twenty years in North, Eastern, Central and Southern India; as also a few weeks' run through several estates in Jamaica, where planting is managed upon scientific principles that Ceylon and Southern India owners would do well to study. I may as well mention that I hold testimonials from several Neilgherry men acknowledging the benefit derived from following suggestions made them by me in the treatment, in all details, of tea, coffee and cinchona. It is just as well at the outset to say that in most cases my suggestions, if acted on, mean, at first increased expenditure, in a more or less degree, dependent on local surroundings; but those who doubt their efficacy might with advantage rake up and carefully peruse a book unjustly forgotten or ignored and now, I fear, out of print, viz., Simmonds' Commercial Products of the Vegetable Kingdom.*

Nothing is more common to read in the planting columns of the Indian and Ceylon papers than querulous and doleful complaints at the beginning of the season, that the blossom is dropping off and the crop in danger from want of sufficient rain to set the buds; no effort to counteract nature's shortcomings is attempted, but all sit down in a hopeless despairing manner and helplessly look at their property deteriorating, like a Mussalman waiting the decree of fate—though without his calmer demeanour. Now, in Jamaica, and in fact all over the West Indies, on every estate large and small, portable hand fire-engines are kept and at once made use of when rain holds off or drought is threatened; in consequence, the crops there maintain a steady average and though it is not possible to combat the exigences of the home markets, it is possible always to put the same quantity up for sale though the profits therefrom may not be so great each year. Whatever the expense of irrigation may be, should it ensure a margin of profit it is far better to incur it than by apathetically staring at the sky vainly imploring *Jupiter Pluvius*, to submit to actual loss. Labor is cheaper, by a long chalk, in Ceylon and India than in the West Indies and it is manifest that if irrigation pays in the latter countries it will do in the former. Water can be led from falls into pits or tanks over the largest estate and one hand engine will be found quite sufficient for 200 acres. The natives of Assam even are far ahead of our Southern planters, for their *pân* gardens are systematically watered by a network of bamboo pipes and thus two months is gained, by irrigating previous to the setting in of the regular rains. When the estate is terraced the conduits can be led behind the plants but the engines will be found, as in Jamaica, the more preferable mode of setting the blossom. Irrigation is the remedy for droughts and those who will not resort to it have but themselves to blame. Those who assert they cannot afford it have no more business with an estate they cannot work than with a horse they are unable to feed. So much for failure through drought.

Next we come to the three B's and red spider. Now a good deal of money has been spent upon attempting to discover a remedy for these pests and eminent scientists have given us full details of their structure, habits and, rather unnecessary, of their depredations. Some fifteen or twenty years back when a Madras Government Official was specially detailed to report on the possibility of eliminating these insects, we in Northern India watched anxiously for the result, and when disappointed made up our minds to accept the inevitable and so conduct affairs as to as much as possible to mitigate an evil, we were obliged unwillingly to entertain. Careful consideration shewed that the best way to meet diseases that would come was to prepare our plants by good cultivation; constant attention to cleanliness, and taxing their powers with moderation to enable them to withstand the ravages of such diseases with the best possible chance of combatting them successfully. The result has been that blight (the leaf-disease) though visiting the N. E. tea estates annually, now does comparatively little damage; as, by judicious nursing, the plants are rendered robust enough to stand its attacks almost with impunity. Within the range of the limestone deposits, indeed, plants either of tea, cinchona, coffee or vanilla enjoy an immunity and this fact attracting attention led to the employment of crushed or rather pulverized limestone, as a manure. One garden that had suffered so severely as to be on the point of being thrown up was thoroughly renovated by the application of two pounds placed round the base of the stem of each plant. The cost of application being for an acre of tea, 2,722 plants, at a task of 500 for 3 annas, a little over a rupee per acre. If there is no limestone in the vicinity the cost of getting it from Bengal would not amount to so much as the indulgence in those highly priced artificial manures at present in vogue.

Lime is the most powerful renovator known (renovation must not be confounded with stimulation whose effects are transient). Lime contains all the elements of strength-giving vitality and, plants, so strengthened, will be as well able to encounter disease as a strong healthy man does. The puny effects from renovating pits filled with cowdung and weeds avail little and cost three times as much as a seer of limestone would. It is unreasonable to expect that our plants of tea, coffee, cinchona, cinnamon or other spices can go on standing the exacting demands constantly made on their leaves, berries and bark without some corresponding nourishment as compensation, and though disease must be endured, our plantations must be strengthened to fight it, even, where it can be afforded, at the expense of abstaining for one whole year from growing a crop, after liming.

SYNTENG.

* A book well-known in Ceylon and dealt with freely in our *Tropical Agriculturist* which we doubt if "Synteng" has seen?—ED.

ABNORMAL APPEARANCES ON TEA PLANTS AND THEIR LEAVES.

St. Rumbold's Estate, Dolosbage, Dec., 30th 1884.

DEAR SIR,—By this day's post I am sending you a tea branch. It caught my attention whilst I was amongst the tea pluckers this morning. I noticed two or three bushes very similar to the branch I send. Can you or any of your referees tell me the cause of this? I shall feel extremely obliged. Wishing the 'Old Rag" a Happy New Year.—Yours faithfully,

J. H. STEPHENS.

[Our scientific referee "cannot account for the abnormal growth. May be caused by the nature of the soil or from atmospheric influences." A Dimbula correspondent sends curiously mottled leaves, enquiring:—"Can you tell me what is wrong with the enclosed tea leaves? One (the green one) appears to be a blight and the spotted one also. They are *very* young plants only out three months." We do not think there is anything more than a slight abnormal appearance due to climatic causes. A South of India tea planter sends us some injured leaves on which the injury may have been caused by some kind of sucking insect—a bug perhaps.—ED.]

RIVAL TEA ROLLERS.

SIR,—The paragraph that appeared in your correspondent's letter, "Pepper Corn" referring to a large Tea Roller manufacturing firm bringing a local inventor to book for an infringement of patent requires notice. I think the firm referred to, will scarcely even care to give trouble. Reports of this kind, have at various times and on various occasions before been in circulation, and no doubt, this now latest one will share the same fate as the former ones. It is a question whether the large firms have not infringed on their smaller brother's patent.

CORRESPONDENT.

COMPARATIVE MERITS OF OLD COFFEE LAND AND VIRGIN FOREST FOR TEA CULTURE.

2nd Jan. 1885.

SIR,—Your correspondent, "Mr. Owen," writes a well-considered letter, (see page 548) that I trust may go far to accomplish a praiseworthy desire of again seeing the hills clothed with verdant green other than weeds, *hoc genus omne*, and "white weed" in particular. But your motive in the series of letters you forecast, of which your correspondent's is the commencement, especially being to give "Innocents abroad and at home" the fullest and most reliable information, corrected (I assume) if possible to date, whereby to lighten their way to the most desirable investment, I trust as a resident and having some experience of tea planting, &c., in the lowcountry, you may permit me space in furtherance of *fact*, and that your correspondent will not fancy I am in the least intending an invidious criticism of his statements, in venturing to question somewhat the more prominent favourable notice he is inclined to give to discarded property upcountry as an investment for limited capital. In fact, that it is really so, that materially less money will suffice to bring such property into profitable yield. Whilst still further venturing to doubt (a point not touched on) its then *comparative* value,—without opening up the question of longevity (which, personally, I do not doubt for tea in either case),—as judged by the maiden returns; of such especial importance to the man who has his all put in, and that "all" *but little*! Mr. Owen makes separate reference to two classes of previously cultivated property for tea; and had his letter appeared a year or so ago, as far as concerns estates still yielding crop, and many of the buildings on them still given some attention to,—what he says for them would possibly hold good (though even here I confess I am largely doubtful!) as regards the lesser outlay needed. But now the tide has turned. I may be wrong—though I hope and think not—in questioning whether any such property with really good buildings and trees yet bearing appreciably, or cinchona in mentionable quantity, are to be had for a song or much below their fair value.

The point then rests, as far as my queries are concerned between fully *abandoned* estates and a conveniently chosen block of land in the lowcountry, with the reserve of wood on it so essentially desirable on a tea estate. Before drawing a comparison of cost, I would say as to the remark made on *soil* to the effect that the lands yet in forest are generally inferior to the coffee districts. That though this may be true for "coffee" the rule does not apply for "tea," and that there remain many thousands of acres as well suited for the latter as any yet felled. Mr. Owen's subsequent and correct remarks relative to the nature of the plant go far as an admission that in reality it is more a question of "subsoil"; and with the experience before us of land in Ambagamuwa previously opened or otherwise, as to what in this respect may be best for tea, and the admitted capacity of the ground on lowcountry estates, I might say without exception, to produce superabundant leaf, it seems to me as far as it may be for a guide to uninitiated investors. Comparisons, here, may be better left out. When any of the newly opened districts shew earlier signs of exhaustion, in comparison to relative returns, it will be time as far as soil goes to say: "friend go not there—come hither!"

Now, as the relative absolute outlay necessary, and the subsequent position under tea, as regards the two classes of investment—*Older* property *vs.* *New* land in the low country. As for estates still in cultivation, as said, I leave them out, supposing their intrinsic and selling values to be again at par? Well (1) for even a totally abandoned place, in the least desirable, Mr. Owen, I suppose, would not expect less than R20 per acre to be the price, which, against for the figure of R30 he sets on unopened jungle, leaves him on the former (but *minus timber*) on 200 acres say R2,000 to the good. (2) Cost of clearing and weeding. The cost of felling on heavy forest may be put at R15 and weeding for the first two years from felling at R15—say total R30 per acre. Now even allowing that the mere 'smell' of a fire-stick is sufficient to do the "clearing," ye *shades* of old Rozel, and *ghosts* of white weed, Spanish needle, and *grasses many*—how much of the above sum (R30) will remain at the end of a like interval, on abandoned land under this heading? From my own experience (not short or incomplete) the moister districts to which alone, as for tea, the discussion can apply, I am afraid I must cancel here the saving on "purchase"! (3) *Planting*—item for pegs is likely to make the cost on old land preponderate inappreciably. (4) *Buildings*—abundant good timber on the spot and sawing at R3 to R4 only per 100 ft. shews here in favor of *new* land, for I do not suppose Mr. Owen wishes it to be understood that on totally abandoned property there will be a saving here; or that if the more permanent buildings are still standing they will not require usually a very large outlay for repairs. The rapidity with which an untenanted house goes to ruin is a proverb; and on a coffee estate in a wet district, especially true. (5) *Roads* on a new clearing in the low country for 200 acres will cost, according to lay of the land &c., say from R800 to 1500,—and supposing (a doubtful supposition though) the old place has been as well as roaded, enough may perhaps remain to meet the difference above in sawn timber and pegs! I am at a loss to think of any other item in which there will be a material saving on either side—except that as Mr. Owen very truly says, work in the low-country is *generally* to be cheaper done.

Here at the end of two years, according to my impression we are "as we were" as regards capital outlay. But let us go a step further in comparing the two investments! Can, as regards weeding, the old place then be supposed to be equally clean or as cheaply weeded? If so, how much of available plant food has not been removed, and is it to be supposed that this has no effect on the comparative growth of the plants? But supposing instead the soil has been enriched by the return of the weeds, how much is this to add to future cost of weeding? —an additional 50 cents per acre monthly represents on the property R1,200 a year! At the end of two, or even the third year from planting, how much leaf per acre may be expected from old land at the higher elevations—coffee-level? In comparison, I venture to say that a successful clearing in the lowcountry, will by then have plucked, or be plucking a first crop equal to the combined maiden efforts of your old estate for it, and the next two years. In one case expenditure by the "poor" man is still to be provided; in the other at least some *profit*, with promise of bumper yields in the immediate future! At the higher elevation what other product is there to be looked to, unless it be a separate field of cardamoms? At the lower an "insurance" that may be added (with cardamoms below) arecanuts and nutmegs in odd corners and ravines, and interspersed amongst it to an appreciable extent without damage to the tea, pepper-vines covering the boulders. I can only conclude with saying as it strikes me that an old estate at discount to be rejuvenated in tea is cursorily plausible, and I don't say a snare, but on comparative showing won't work out.

YOU PAYS YOUR MONEY AND YOU TAKES YOUR CHOICE.

YIELD OF TEA AT A HIGH ALTITUDE IN CEYLON.

Abbotsford, 5th Jan. 1885.

DEAR SIR,—As we are commanded "in all things to give thanks," I feel it my duty to commence even such a wordly thing as a tea report by recording that "goodness and mercy have followed us."

Writing on the 5th Nov. 1883, I said: "From what I know now of pruning and plucking I can almost certainly, if all goes well, guarantee 500 lb. per acre next year." It is true that in July of 1884, in giving statistics for six months from January to June I foreshadowed a steady rise to 600 lb. per acre, but I did not, I now find, make sufficient allowance for the consequence of pruning out of season. The grand flush has only come on during the last six weeks, so this year (1885) will reap the benefit. I will not now venture to prophesy what I expect this year, as I find that my vaticinations of last year were, in the process of passing from mouth to mouth, exaggerated to a definite report that we had already dispatched 800 lb. per acre and were consequently rolling in wealth! As most Ceylon tea planters will find, 500 lb. per acre helps to pay the expenditure, on existing and extended culture, but does not make a man's fortune all at once.

Although I gave details in July respecting manuring, pruning, &c., I had better recapitulate them here. Of the 110 acres, 15 acres (the cattle-shed field of which a separate account follows) were pruned in August, 1883; 5 acres (the bungalow field) in February, 1884; and 90 acres in March, April and May, 1884. None have been touched since. All the prunings were buried and a small amount of cattle-manure, ravine stuff and ashes were added where available. The whole acreage has been once forked during the year, and a second forking is now in progress. If I could spare the labour I would fork thrice times in the twelve months, as this seems to mean double flush.

As regards the number of picking days, it will be seen that we only availed ourselves of 245 out of a possible 312 week days: this was to avoid Sunday work if possible, and I am certain we have by pursuing this course suffered no loss. We picked two or three times during the year on Saturday because the weather was wet and the leaf would keep till Monday. The figures below do *not* include the tea plucked from our young plants. I mention this as the same doubts were most ungenerously cast upon the Mariawatte yield.

The yield off the acreage reported on, was for 1883...	34,293 lb.
against a yield in 1884 of ...	55,723 lb.
making an increase in 1884 over 1883 of	lb. 21.430

The make for the respective months is as follows:—January, 4,906; February, 8,886; March 4,458; April, 6,096; May, 3,903*; June, 868*; July, 863*; August, 1,132; September, 2,377; October, 5,188; November, 6,288; December, 10,758. Total 55,723. From the December figures it will be seen that we made at the rate of 97·8 lb. per acre for the month, or 1,173·6 lb. per acre for the year, could such a rate be sustained.

Below are the figures for the whole 110 acres:—

ABBOTSFORD TEA ESTATE.

Returns from 110 acres, 7 and 8 years old, January to December 1884. Altitude 4,600 to 6,000 feet above sea. 15 acres unpruned: 95 acres pruned February-June. Rate, 506½ lb. per acre.

No. of Week.	Week ending.	Tea Made.	Total Tea Made.	Average per acre per annm.	Rain-fall.	No. of Days Picking.

In giving separate figures for the 15 acres cattle, shed field, some remarks are necessary. The bushes on this field were pruned in August 1883, and as an experiment have not been pruned since. In 1883 they yielded 425 lb. per acre, and in 1884, without the process of pruning being resorted to, they have given 521 lb. per acre and are still flushing profusely. At the time of pruning all branches were buried, and about 10 acres had cattle-manure and ravine stuff added to the holes. The field has had one forking, and has been picked in 40 rounds, which means as many flushes. Half of the tea on this field is nearly pure China or China hybrid, but a large proportion of the bushes present a broad surface and flush well. We see no necessity therefore for removing this tea (which was sold to us a good hybrid) but our seed bearers (first class hybrid) are at a distance from this field. About September this got a severe attack of bug and turned quite black in the face, so that for many weeks that delightful maudenly flush that gladdens the manly heart could not be seen. Otherwise the bushes were in nowise injured, as will be seen from the following details:—

* Effect of pruning.

Cattle Shed Field.—15 acres—Jany.-Dec. 1884 (not pruned since August 1883). Rate 521 lb. per acre.

Date.	Round.	Green Leaf.		Made Tea.	Rate per acre	per annum.

The above information will, I know, satisfy and gladden the hearts of many possessors of tea, or land intended for the culture of the plant at high elevations. I am confident, that, if no unforeseen circumstances intervene, the returns of the present year will show a still better result, and that tea is destined to be a grand success in Ceylon equally at high elevations as at lower levels.—Yours truly, Messrs. Editors and brother-planters, A. M. FERGUSON, JR.

P. S.—Any honest and open comments on the above will be freely answered to the best of my ability.

It is only right to say that the picking which yielded the average of over 500 per acre, was restricted to the bud, the first developed leaf and half of the second leaf. Mr. Thomson of the great London Tea Firm said "If you get 500 per acre of such tea, the yield is very good."

TEA DRIERS.

Colombo, 7th Jan. 1885.

SIR,—In your issue of the 5th inst. we notice Mr. Kinmond's letter, and in reply thereto we can only again point out to planters, that, notwithstanding the recent reduction in the price of Kinmond's driers, there is still a difference of *over* 40 per cent. in favour of the No. 3 Sirocco, without taking into consideration the cost of motive power, the possibility of an occasional break-down of the steam engine and the liability of the pans to get out of order. It is generally admitted by planters in Ceylon and India that the Sirocco takes *first place* as regards the *quality* and *flavour* of its tea, and in confirmation of this we can only refer to the fact of nearly 800 machines being in use. Indeed it has been stated by an authority that all the other machines in the market put together have not reached so large a sale as the Sirocco. With regard to the only two advantages Mr. Kinmond mentions in favour of his machine, a saving of fuel and space, are they equal to those we claim for the Sirocco? Planters have unmistakably given their verdict. Where you will find 60 Siroccos at work today in Ceylon you will not find half-a-dozen Kinmonds, although they have been before the public for many years past.—Yours faithfully, W. H. DAVIES & Co.

A NEW TEA COMPANY.—The Eastern Docars Tea Company, Limited, has just been registered. It is formed to acquire tea gardens, plantations, factories, &c., known as Tamai, Hat, and Mornai River Tea Estates, in Goalpara, Assam, and to carry on all the business connected with same, &c. Capital, £20,000, divided into 500 shares of £10 and 1,500 deferred shares of £10 each.—*Home and Colonial Mail.*

A NEW INDUSTRY.—It has often been a cause of wonder why the fine flavoured cocoa grown in the island of Trinidad was not manufactured into chocolate on the spot, instead of being being all sent to Europe for that purpose, and returned there in that form for their own consumption at a much higher price, and to a certain degree of deteriorated quality. The problem has at last been successfully solved by the manufactory established there under the management of Mr. J. Schæffer. With the appliance of the latest and best description of machinery chocolate of the choicest quality is made in Port of Spain from the finest cocoa grown in Trinidad and Venezuela, equal in very respect to the Menier brand which has acquired such eworld-wide reputation.—*Colonies and India.*

TEA ROLLERS.—Readers familiar with tea machinery will have seen that in the letter from the Hills, in yesterday's paper, the names of Jackson's rollers were transposed. It is the smaller one made for power which is called the "Universal," the larger being styled the "Excelsior." The latter machine generally requires engine-power, we are told, a water-wheel of 16 feet not being of sufficient power to work it; wheels of 21 to 30 feet, indeed, being taxed to their utmost to perform the task. Turbines have the advantage in this respect. Meantime, we are told that the Jackson's hand-roller manufactured by Messrs. John Walker & Co. when adapted to water-power and with certain improvements, is calculated to do as much work as the "Universal."

TEA PLANTING IN MASKELIYA.—We are glad to learn that Mr. H. D. Deane has so much faith in the future of tea in this district that he has bought his father out of *Kintyre* estate at the rate of £14,500 sterling: the price is a large one, but there is good reason to hope that Kintyre will turn out a second Mariawattie. The young tea is coming on very well, and Mr. Deane has started a central factory here in conjunction with Messrs. Rathbone Brothers of London and Liverpool who we are very glad to learn, are turning their attention to Ceylon tea and who are represented in the island by Mr. A. R. Blandy who has had eight years' experience in China as buyer and taster and five years in the Lane." Mr. Deane further hopes in a fortnight to have a No. 3 Sirocco at work as well as a Gore's Sifter. It will be interesting to watch the development of the great industry in Maskeliya.

THE APPLICATION OF LIME.

TO THE EDITOR OF THE MADRAS MAIL.

SIR,—Referring to "W. H. C.'s." letter regarding the application of lime to coffee, I would advise him to have renovating pits dug (say 3 feet long, 2 wide, and 2 deep) between every four coffee plants, into which may be deposited a quarter of a bushel of lime, together with all the weeds, rubbish, &c., about the place. This should be done immediately after pruning, as the cuttings and leaves would come in handy to fill up the pit. This system was adopted on the "Hallacary" estate with great success.—AN OLD PLANTER.

FRUIT TREES.

As a fair illustration of the advantages of planting nice, hardy dwarf orange trees over the planting of large trees, we have seen that the large plants have died away during the previous dry weather, and the hardy dwarf young trees have maintained their own, and are now growing apace. The question of the apple moth has lately again come before the public, in the way of its introduction from America in the apples now being extensively imported from that country. The Colonial Treasurer, instead of allowing the entire cargo to be landed and dispersed, should have had them warehoused and the fruit repacked into fresh cases, thereby preventing perhaps the escape of miltitudes of the moths. It is all very well to say we have the trouble here, but as it is not very prevalent, it would be just as well to try moderate means to prevent it coming amongst us by the thousand, and that can be easily effected by resorting the fruit, under the supervision of a prominent officer. With respect to the fruit itself, our previous opinion still holds good, that while it is pretty to look at, it is, as regards quality, worthless for dessert purposes. So that when our apple crops are ready, growers need fear little for the American fruit, which evidently, if the varieties possess any, loses its goodness by the long sea voyage. In previous articles we took occasion to allude to the common damson as producing generally immense quantities of fruit, thereby rendering its cultivation valuable for preserving purposes. It was thought it was an American variety; but from an article, with illustration, in the *Gardeners' Chronicle*, it appears to be the true English damson, rendered possibly less austere by the influences of our climate.—*Sydney Mail.*

REVIEW.

INDIARUBBER AND GUTTAPERCHA: *being a compilation of all the available information respecting the trees yielding these articles of commerce, and their cultivation, with notes on the preparation and manufacture of Rubber and Guttapercha.* Compiled and published by A. M. & J. FERGUSON, of the *Ceylon Observer*, Colombo, Ceylon.

The publication of this little volume presents a further evience (if any such be needed) of the growing importance of the Indiarubber industry. The efforts recently made and still in progress in Ceylen and other parts, to develop new sources of supply, and realize a profitable industry in the cultivation and preparation of the raw material, have led to considerable enquiry on the subject. Many of the planters of Southern Asia have naturally appealed to Messrs. Ferguson, whose *Ceylon Observer*, *Tropical Agriculturist*, and other publications are well known as mines of information on all topics connected with colonial enterprize in those regions. In response to these appeals, the little work before us has been compiled, by collecting from a large number of sources a *resumé* of all that is known at present about Indiarubber and Guttapercha. At the present stage of the Indiarubber growing enterprize in Ceylon, the compilers have not found it practicable to compare the statements of the different writers with local experience. They modestly say, "As a preliminary to the *Ceylon Rubber Planter's Manual* of the future, we have simply republished what is said about Indiarubber by every authority or compiler within our reach; and although a great deal of the matter may be found reprinted more than once, we have thought it best in the first instance to give the extracts *verb tim*, so that the amount of authority attaching to each statement and opinion may be fully and readily seen." By compiling and placing side by side the information collected by these eminent observers and experimenters, Messrs. Ferguson have done good service. It must not be supposed that the work is confined to the raw material and its production. The geographical distribution and botanical characteristics of the various plants yielding Indiarubber are, indeed, copiously treated of, but we have also a considerable amount of valuable information on the chemistry, manufacture, and industrial uses of the material under notice, as well as some description of the machinery used in its manipulation. For the benefit of those wishing to investigate these matters more thoroughly, there are lists of works (both English and foreign) specially treating of the above-mentioned topics.

Our remarks will serve to point out the character of this new contribution to rubber literature, and we shall, no doubt, from time to time recur to its pages in connection with various subjects that may come under our notice.—*Indiarubber and Guttapercha Journal.*

FOREST ADMINISTRATION IN BRITISH BURMA.

In the Supplement to the *British Burma Gazette* of last Saturday is published the Resolution on the Forest Administration of British Burma for the year 1883-84. From this we learn that the work of the Forest Department is progressing favourably, and that notwithstanding the recent fall in the price of Teak, there is a small increase in the gross revenue of about five thousand rupees. As the expenditure was reduced by about R11,000 at the same time, there is an increase in net revenue of about R16,000. The net revenue is now close on thirteen lakhs of rupees, and as fresh areas are still being brought under reserve, and larger areas being successfully protected against fire, we may look to the income from the forest increasing year by year. We see that there is an increase of fully ten per cent in the proceeds of minor forest produce; and that if bamboos, firewood and charcoal be included in this, the total revenue from this source is close on a lakh of rupees. * * * *

There are now 3 346½ square miles of area reserved for forests in British Burma. This seems a great deal, but when we remember that the area of British Burma is 87,220 square miles, the greater portion of which is merely wasted; that there is not nearly sufficient population to till it, nor likely to be for many years to come; and that the country is eminently suited to the growth of many valuable woods; then, remembering these things 3,000 square miles seems a great deal too little, and we trust that the Department may go on steadily adding to its reserves. It can do a great deal in that way for many years to come without any fear of encroaching on ground really needed by the population; and that is the only check we see which need be put on the extension of forest reserves,—unless, of course, their increase is to increase our rainfall *pari passu*. We do not quite know how far the connection between forests and rainfall holds good. If the doubling of our forest reserves meant, for instance, a doubling of our rainfall also, we should object to it very strongly. We get quite enough rain as it is and have no desire for much more of that.

The experiments in the introduction of exotic and other trees do not seem to have been very successful. The rubber trees of different kinds have not generally thriven. The number of vanilla plants has increased at Magyi, but the few pods which have appeared have been eaten by squirrels and ants. Vanilla, we imagine, requires more individual attention than it can receive at the hands of a Forest department. Its cultivation is eminently one of those minor industries by which the women of a family can eke out a scanty income; but that is apparently exactly what the wives and daughters of struggling men here do not try to do.

The Mahogany trees at Amherst have very largely suffered from the attacks of insects, and the experiment is not considered promising. This is disappointing, and as some at least of the mahogany trees in the Cantonment Gardens seem to be doing well, the comparative failure at Amherst is all the more surprising.

Coffee plants in the Pyunchaung reserve, Toungoo division, have not thriven, but some 3,550 plants at Thandoung are flourishing. At the same place there are also 756 tea plants

also doing well. A sanitarium for troops has now been established at Thandaung, so there is clearly a fine opening for any enterprising man to establish himself there, in a good climate, as a tea and coffee planter. That would give Burma a new industry, and attract foreign capital into other channels than the rice and timber trades, both of which are the reverse of flourishing at present.

Something has been done also, though not very much, in getting Burmese forest-rangers trained. Three out of the five Burman apprentices at Dehra Dun passed out of the Forest School at the end of 1883, one with, and two without, certificates.—*Rangoon Gazette.*

DRAINING OR TRENCHING FOR COCONUTS.

TO THE EDITOR OF THE [CEYLON] EXAMINER.

SIR,—It does seem strange that so necessary a branch of the proper and husbandmanlike cultivation of the Coconut is so universally neglected. But then the Coconut is seldom systematically cultivated, it is simply allowed to grow. Weeding a Coconut estate generally receives the exalted term of cultivation, and if a man more intelligent or less apathetic than his fellows acknowledge the necessity of giving back something to the soil for all he his taking out of it, and manure his land, he is supposed to go in for "high cultivation." The Coconut receives fair and generous treatment only on such poor sandy soils as refuse to give up elements of fertility they do not contain; and absolute necessity is made a virtue of.

Now to my subject. Trenching is taken up by some to prevent "wash," by others not to be behind-hand with their neighbours. I unhesitatingly assert that there is absolutely no *wash*, in the general acceptation of the word, on a well-grassed land. The soil is so firmly bound by the roots of the grasses, that not a praticle can be displaced by wash. The grass filters and arrests all soil held in solution, even in water rushing from the sidedrains of roads, wherever such bound grassed land. I had an opportunity of witnessing this while travelling once on a road during a heavy rainstorm. A large stream of water washing through and over a road, found an outlet in a thick and muddy condition on a Coconut estate skirting the road. Before the water had gone twenty yards, it was flowing as clear as if passed through a filter! Droppings of cattle, even when dissolved by rain, rarely travel beyond a foot of where they were deposited. The only part of a Coconut estate, where rain-water carries along with it any loose soil or decaying vegetable matters, is in a hollow or ravine, and this is owing to the accumulation of water from all sides towards this hollow. Careful trenching, by arresting water before it reaches a hollow, can avert even this slight amount of wash.

Those who resort to trenching to arrest wash throw the soil dug out of the trench on the upper side of it. The absurdity of this becomes apparent with the first heavy rainfall, as the trench, not being traced at any gradient or even level, the accumulation of water, wherever there is a depression, causes the earthwork to give way, and the rush of water in a volume does all the damage tenfold increased, which trenching was thought to prevent. Every successive rainstorm widens the breach and weares away the earthwork. But I will possibly be told that this soil carried away at the breach is caught by an ingenious contrivance for a silt trap designed and used by certain planters, consisting of a fence of life sticks put down at every trench, and protected by rubbish and the branches of the Coconut. To my mind the game of digging trenches so that the soil thrown up above it is caught in a trap below it, is more expensive than ingenious.

If there be no wash on a Coconut estate, where is the necessity for trenching? Not to mention the benefit to a soil in its aeration and increased porosity resulting by a system of trenching, it has the additional merit of storing up and slowly dispensing to the Coconut the moisture it revels in, and which is so much of a necessity to mature its nuts. It is not necessary for me to assert that it is more beneficial for a soil to have rain water stored at intervals and slowly filtered through it, parting with the fertilizing matter it holds in solution, than for it to wash over a soil. Saturated as such a soil is with water, it will be better able to stand a prolonged drought, than if the water had passed over it, without saturating it to any appreciable extent. I would not cut trenches, as I have always seen done, over long unbroken lengths and to a great depth; and for these reasons. Trenches are cut between the lines of Coconuts, and these do not invariably run at right angles to the slope of the land. Consequently, all the water accumulates at the bottom of a slope, and finds an exit there, and only those trees are benefited, where there is an accumulation of water, while it becomes a question whether those at the top are not in a worse plight than before, by having all the moisture, that otherwise might have been there, drained from the roots. And I will not have trenches deeper than a foot or eighteen inches, as the water caught in trenches three or four feet deep is likely to sink beyond the reach of the roots, for, remember, except in very free soil, Coconut roots are seldom found below eighteen inches, and deep trenches are likely to drain off too quickly the moisture in the soil. It is best I think to cut trenches in sections of say twenty-five feet, making the bottom as level as possible by cutting deeper where the land is high and less where low and throwing the soil on the lower side. The advantage of cutting trenches in sections is that each section holds whatever water falls above it, benefits the trees adjoining it both above and below, and does not allow the water to flow down to the bottom of the slope and be lost. It is also necessary to fill the trenches with all the droppings from the trees and with weeds, both to prevent too rapid evaporation of moisture, and as manure for the trees, opening new trenches between the old ones as the latter fill up.—Yours truly,

AGRICULTURIST.

PLANTING IN QUEENSLAND.

TO THE EDITOR OF THE LONDON TIMES.

SIR,—At a time when there is so much talk about Imperial federation, it may somewhat startle your readers to find that one of your youngest colonies, Queensland, desires subdivision, and is very much in earnest about it.

This desire, which has been mooted at various times during the last 20 years, has now come to a head, owing to the entirely diverse interests of tropical and sub-tropical Queensland, and also to the chief industry of the former, sugar-growing being threatened with utter extinction by the political representatives of the latter.

There are 55 members in the Queensland Legislative Assembly, of whom three-fourths are derived from the sub-tropical and more thickly inhabited districts. It is consequently impossible for tropical Queensland with its vast territory and 1,500 miles of sea coast to make itself heard or to obtain justice.

The main point upon which the two portions of the colony are now at variance is the question of the introduction of coloured labour. The inhabitants of tropical Queensland declare they cannot exist without it; those who live in more temperate regions do not see the necessity.

Let me give a short history of the development of the sugar industry in Queensland. On this very day 25 years ago, in 1859, Queensland was separated from New South Wales, and in 1862 were issued the sugar and coffee regulations granting land on favourable terms to people introducing these industries, and the following year an Act was passed to regulate the introduction of coolies from India. Induced by the encouragement thus held out people began in 1865 to invest their capital and energies in the business of sugar growing, till, by the present year, over £5,000,000 of money had been invested, and the estimated gross annual value of the produce was £1,000,000, while the value of the gold exported was only £800,000, and of wool £1,300,000. The Government of Queensland, in applying here lately for a loan of several millions, were therefore justified in drawing attention to this industry as constituting one of its main securities.

But the same Government now deny that labour by which alone the industry can be made profitable. Up to the present time the growth of the industry has been entirely dependent upon the coloured labour obtainable from the South Sea Islands; but that supply is now getting very limited, besides presenting other and objectionable features.

But the planters applying to have the Indian Coolie Act put in force, the Government replied by repealing the Act, and, moreover, as an attempt was made to get some

Chinese labourers, they passed an Act on March 10, 1884, imposing a poll-tax of £30 on every Chinaman entering Queensland, and limiting the number to be carried by any vessel to any port in Queensland to one Chinaman for every 50 tons of tonnage of such vessel. Moreover, they passed a series of cast-iron regulations, which utterly strangled the importation, under Government supervision, of the inhabitants of Polynesia, and all the vessels employed in that business were consequently withdrawn.

Against these successive acts of tyranny, the planters being left without any source of coloured labour, and seeing themselves brought face to face with absolute ruin, have, in conjunction with their army of skilled *employés*, now rebelled, and demand separation from a Government which has thus broken faith with them, and by not carrying out the promises of previous Governments have obtained, under false pretences, their labour, capital, and energies for the last 20 years. It is useless to talk of tropical cultivation without tropical labour; in no part of the world is such a thing attempted. Those who live in temperate regions do not know what they are talking about when they suggest white labour, irrespective of the cost, which would be absolutely prohibitory. The difficulties of sugar-growers all over the world are bad enough at the present time, owing to bounty-fed beetroot produce; but when, in addition to the lowest prices known during the present century, also to (in Queensland) three bad seasons in succession, there is superadded legislative interference of a vexatious and persecuting character, you cannot wonder at the desire for separation, which will only enable the residents in tropical Queensland, by importing coolies from India for tropical cultivation along their extensive coast-line, to put themselves on equal terms with the inhabitants of the other sugar-producing countries of the world. Trusting, sir, that this letter may explain in some measure the telegram from Queensland which appeared in your Second Edition of today.—I remain, your obedient servant, J. EWEN DAVIDSON, a Queensland Sugar-planter for 20 years, 35, Harley-street, London, Dec. 10.

[Mr. Davidson who, after experience in the West Indies, became one of the leading sugar planters in the Mackay district, represents the position very fairly. The planters ask for cooly labour in connection with which many Europeans would be employed, one white for every seven blacks, probably. But the Griffith Ministry put the ban on cooly immigration, and propose instead to introduce Germans and Scandinavians to compete with English labourers on lower wages generally, a policy which neither the planters nor the workingmen are likely to appreciate. The remedy is undoubtedly separation.—ED.]

TREE-PLANTING IN VICTORIA.

The report of Mr. William Ferguson on the State Nurseries and the forest regeneration at Mount Macedon, is a very interesting document, not only as showing the work that has been done, but also what may be done in that direction, and the ease with which it may be accomplished, and proving that the very important work of forest regeneration rests entirely upon the Government and the Parliament of the colony providing the necessary funds. Had these been dealt out more liberally, there is no doubt that instead of one or two hundred acres, as many thousands would, by this time, have been progressing. It appears that an area of seventy-five acres on the Mount has been fenced and cleared during the last two years, but only forty acres have been planted, though we know that the trees were ready for being planted in that ground three years ago, but the means were not forthcoming. It is gratifying to find, though not surprising, that the trees first planted, eight years ago, on the Mount are doing well, thousands of Californian Pines having attained an altitude of twenty feet; while hard-wooded European trees have done equally well according to their kinds. Though a growth of twenty feet in eight years is not excessive, the bleakness of the situation must be taken into account, for that is most unfavourable to the progress of young, and especially of transplanted, trees.

The most effective mode of reafforesting is that tried in the Majorca State forest reserve, where about 200 acres were sown this year with *Acacia pycnantha*, and about twenty acres of Blue Gum, which have done well, and promise to become a valuable plantation. Altogether there are about 400 acres of wattle plantations formed in the district.

As a proof of the efficiency of sowing the seeds where they are to remain, it is stated that—'The plantations of Blue Gum (thirty acres) sown broadcast about four years since in the State forest reserve, have now attained the height of about twenty feet and twenty-five feet six inches in diameter, and promise soon to become of considerable value for mining and other purposes.' Also at Longerenong a paddock of sixty acres, adjoining the nursery, was set apart for wattle cultivation, and thirty acres have been sown with black wattle (*Acacia decurrens*), and are growing very well. And Mr. Ferguson recommends the remaining thirty acres to be sown with Golden Wattle (*Acacia pycnantha*), which, he believes, will prove the most remunerative for cultivation. 'In the nursery department during the past year a great amount of the available labour was employed in taking up and packing trees for public bodies, water supply, and State schools in all parts of the colony. From Macedon Nursery during 1882-83 upwards of 85,000 trees were distributed gratis to 550 public bodies, State schools, and Government institutions and works; and from the Wimmera Nursery at Longerenong 1,145 trees were supplied to shire councils and public institutions. This work employed one-half of the nursery staff, and sometimes more.' The portion of the report relating to the ill-chosen Longerenong Nursery is not at all unfavourable, and considering the arid nature of the climate, many European and other trees have succeeded well, even including the sycamore. Among those transplanted in that nursery the catalpa, which produces very valuable timber, is worthy of every encouragement; but we fail to see the use of propagating such things as laburnums or *Amorpha fruticosa*. The wattles on the railway reserves are alluded to, and Mr. Ferguson considers they have made rapid growth.

From the appearance of the wattles along the Geeloog line of railway, it would seem that they are not likely to prove a profitable speculation, as they are making a comparatively poor growth, although the soil, for the most part, is of good quality. We think the variety used is of the wrong kind to yield a profitable return, for though the bark of the golden wattle (*Acacia pycnantha*) is more valuable than that of the black wattle (*A. mollissima*), the tree is much slower growing, and requires double the time to yield a given quantity of bark than the black wattle, which has been known to attain a height of fourteen feet the first year, whereas those on the railway will require five or six years to reach that height. We are not aware in what manner the ploughing of the ground was performed; we only know that it cost an immense amount of money. However that may be, it has certainly not been properly treated since, so that the wattles have not had a fair chance. The seed ought to have been sown in rows rather thickly, so that the ground might have been ploughed once a year, so long as requisite, to loosen it and keep the weeds down; these would have acted as manure, the roots would have had a better run, the trees would have drawn each other up, and less pruning would have been required. Then the plants could have been gradually thinned out as they attained sufficient size for barking. There is another obstacle to the well-being of wattles on such a situation; they are sociable trees, thriving best in company, and therefore succeed better in a large group then in a narrow strip; they also love shelter, but here they are exposed to winds both cold and cutting. So that, taking all circumstances into account, the probability is that the money expended will never be returned.—*Leader.*

BLUE MOUNTAIN TEA.—Large numbers of articles have been tried as substitutes for Chinese tea, but they soon fall into disuse. This is not the case with the sweet-scented golden rod—Solidago odora. Its use commenced among the Germans in the interior of Pennsylvania, probably fifty years ago, and has continued to grow in popular estimation until it has become the exclusive drink in many sections, and has actually become an article of considerable commerce. Large quantities are now sold in Chicago at $1 per pound. Unlike many virtues it has not been palmed off as "Chinese tea, native of Pennsylvania," but is sold for just what it is, and it has worked its own way without trade tricks.—*Gardeners' Monthly.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, December 18th, 1884.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.

"CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AND ENERGY."

We now give a second instalment of the papers on this subject. Our correspondent today—a planter of prolonged and varied experience—has chosen to throw his relation of experience and advice for men meditating investment in Ceylon, into the form of a couple of letters. These are supposed to be addressed to a young friend in the old country who has applied for information respecting the Ceylon planting enterprize and the prospects before investors. How well these supposed questions have been answered, we leave our readers to judge :—

My dear ———,—I shall be happy, as desired, to tell you something of my Ceylon experience, giving you some hints therefrom and my opinion as to the advisability of your coming out to and investing in this country. My local experience as you are aware extends considerably over a score of years, during which I have seen many ups and downs, felt many hopes and disappointments, sometimes with the wise man learning at the expense of others, at other times with the fool at my own.

I early turned attention to what are now styled New Products, working up all the formation I could gather both from men and books. Without capital, however my speculations were but theoretical, all the planting of many an interesting and hopeful product being done in the gardens of castles in the air, and hope deferred soon made the young heart sick. Nevertheless, so novel were such thoughts in those jog-trot days of the one great staple—coffee, that friends regarded me as a visionary, more theoretical than practical, and one Colombo agent, a fine true-hearted kindly gentleman, now alas! no more, shaking his head, spoke of me as a good planter, but *very* speculative. The cry *then* was : stick to coffee, keep to the beaten track ;—*now* it is : plant up new products, don't have all your eggs in one basket.

With time at length came savings, credit and what are called chances ; but I had to forego my aspirations for the new, and start with coffee. Then came the earth hunger, investment after investment, buying and selling more or less to advantage, credit making credit, and with fair crops and handsome realizations, all finding fuel for future combustion. Gradually at first, unexpectedly rapid at last, things changed for the worse. Leaf-disease appeared, and yearly spread and intensified. In spite of much intelligent thought, hard work and high expenditure, crops fell off, prices followed, credit became restricted, cultivation was lowered, and at last our very coffee trees are disappearing before the advancing attack of black bug. Probably there is not one estate proprietor in Ceylon who trusts alone to coffee now, while the future is very dark indeed for him who has not largely planted up the old product with the newer cults. When the seriousness of leaf-disease grew evident, my thoughts were turned to the loves of my youth. In small ways I tried a whole host of minor cultivations. But too often, even when the requisite knowledge was acquired, the answer to the question, Will it pay ? was unfavorable. In some instances the natural difficulties arising from climate and soil were unsurmountable ; in others, thieves, vermin and strange pests took more than the lion's share, while of most, one quickly found how very soon supply might overleap demand. As regards the major and now no longer new products—cinchona, cacao, cardamoms, tea, Liberian coffee, &c., I did of course, and have continued to do what I could, but with credit clipped and capital exhausted, means and time have failed to thus adequately fill up the void created by the rapid decadence of coffee.

If however, the continued struggle has become almost hopeless for many an old proprietor, it is not so for the country itself. The ownership of large areas of no longer profitable coffee and of fields that were of cinchona, together with an ever-growing accumulation of old advances, debts and liabilities, with interest, compound interest and annual charges piled high over all,—such a load, clinging more tightly than Sinbad's man of the mountain, weighing more heavily than Christian's burden,—may indeed swamp many a weather-beaten craft, but freed from indebtedness revivified by fresh capital, the estates themselves will again get a fair chance and do well. This digging out of old stock and replacing it with new blood may be a very painful saddening thing for some; and they, nobly struggling to meet liabilities, *are* to be pitied ; but the sooner it comes the better will it be for all. Ceylon, with its unrivalled climate, equally so as a tropical country for animal and vegetable life, with its abundant cheap supply of labor, its admirable system of communcations, with its energetic progress, its hard-won experience and its daily press, will again attract a new set of investors, who, buying far below intrinsic values and profiting generally at the expense of their predecessors, must while enriching themselves, restore prosperity to the Island itself.

There are still certain New Products that have not yet, but will in time make a name for themselves. In the low-country particularly a good time and an enduring time will undoubtedly come some day when land there becomes cheaper and more accessible. But for the immediate future it is to tea we must look as the means that will largely bring back rich, warm blood to the heart and mainspring of the community—European enterprize. Cinchona will continue to be profitable in strangely favored patches; cacao will yield long, steady, easily-made returns in suitable localities ; cardamoms for a time will give little fortunes ; and other things in their order will help ; but for general, great and speedy regeneration *tea* must and will take the place of our old and favorite staple.

Thinking I have now done more than justice, any way as to space, to the historical part of your request I now more briefly proceed to give you the advice you seek. If you really desire to lead the life of a planter and to profitably invest capital in the East, then, if willing to work hard and thoroughly learn your business, to live as you should in all things and not to invest till after you have acquired the requisite knowledge and experience, then by all means come to Ceylon and go in for tea. There are worse places than Ceylon to live in, and its charm grows with residence. Ceylon possesses exceptional advantages for the production of tea, good in quality and at low cost. There are few, if any, of the larger tropical products more likely to bring in quick, steady, certain and continued returns than tea when judiciously planted and cultivated in Ceylon, and in the coming struggle with rival producers it will more than hold its own.

Should you feel inclined, as I expect, to act on my advice, I shall be pleased then to give you for guidance a few hints and lessons from dearly-bought experience and observation.—Yours truly, ———

GEMS AND GEM-DIGGING IN CEYLON.

(Communicated.)

It is now over thirty-seven years since the late Dr. Gygax wrote the results of his geological and mineralogical researches for Sir J. Emerson Tennent. In describing his examination of the southern slopes

of the great Himapahura range of mountains above Boltumbe and Bambarabotuwa, he says:—"I found about the middle of the ascent a stratum of grey granite, containing, with iron pyrites and molybdena, innumerable rubies from one-tenth to a fourth of an inch in diameter, and of a fine rose color, but split and falling to powder. * * * I carefully examined all the minerals which this stratum contained felspar, mica, quartz malybdena and iron pyrites, and found all similar to those I had previously met with, adhering to rough rubies offered for sale at Colombo. *I firmly believe that in such strata the rubies of Ceylon are originally to be found*, and that those met with in the white and blue clay at Balangoda and Ratnapura are but secondary deposits." And Sir James adds, probably on Gygax's authority:—"It is highly probable that the finest rubies are to be found in the abovementioned strata, perfect and unchanged by decomposition, and that they are to be obtained by opening a regular mine in the rock, like the ruby mine of Badakshan in Bactria, described by Sir Alexander Burnes."

I was very intimate with poor Gygax and frequently accompanied him in his exploring excursions. He constantly urged his reasons for recommending that the search for gems should be undertaken on scientific principles, but in those days we were all so certain that we should make rapid fortunes by coffee-planting, that it seemed absurd to think of wasting time in any other speculation.

Although the operations carried on in the search for precious stones are still of the same rude and primitive character as they were at the time Gygax wrote about them, yet their localities have extended very considerably, and of late years they have been put in practice on the sides of the Himapahura range. About two years ago, native diggers flocked in large numbers to Bambarabotuwa, spreading over a considerable extent of ground. Near Kekunagahadola, fully a thousand were at one time congregated and were hard at work digging pits and washing the excavated earth. The pits are generally about 12 feet deep, and the same in diameter, as the rainfall is heavy in this part of the island the work of baling out the water absorbs a large portion of labor.

For obvious reasons the diggers keep the results of their exertions very much to themselves, and no information that can be relied on is to be obtained respecting the value of what they find. Speaking of the same stratum alluded to in the above quotation from Sir J. Emerson Tennant's book, Dr. Gygax adds "that having often received the minerals of this stratum with the crystals perfect, he had reason to believe that places were known to the natives where such mines might be opened with confidence of success." I cannot agree in this opinion, although I have no doubt that there are many natives in possession of experience that would be very valuable to a stranger who might wish to commence the search for gems on a regular system.

The accompanying three sketches with the corresponding outlines are intended to give an idea of the country which produces the greater portion of the precious stones sent from Ceylon.

No. 1 is taken from the Bulattota Pass, looking towards Adam's Peak. The distant range of mountains to which Adam's Peak belongs is the Himapahura. Ratnapura lies at the foot of the range to the left, and Balangoda lies close under Pitigalkanda to the right.

No. 2 is a view of part of the valley of Bambarabotuwa; about the centre of the view is Kekunagahadola, where the diggers have been assembled for nearly two years in large numbers. At first they were interrupted by the authorities of Ratnapura, and much law-business had to be got through, in which the diggers rather scored than otherwise, and the proceedings of the authorities were somewhat mixed. Since then an ordinance has been passed which regulates the digging, the terms of which seem to be very reasonable, and it is strange that the enterprize of searching for precious stones has not been taken up by capitalists on some recognized system.

No. 3 is a digger's hut in the Hapugastenna forest, on the right bank of the Weweldola. A guide from the nearest village of Dehinoakanda, in pointing out this stream, remarked in a general kind of way:—"If anybody wants to find plenty of valuable gems, let him turn this stream and dig in the bed thereof, and he will find them to a value beyond the dreams of avariee," or worde to that effect.

The above was written about two years ago, during which period I have no information as to the gem-digging enterprize.

A BRIEF ACCOUNT OF THE STATE OF NATIVE AGRICULTURE DURING 1884, IN CEYLON.

(From a Sinhalese Gentleman.)

The Paddy Crops of the "yala" season almost all over the island, on which the natives mainly depend for their supplies of rice during the year, were damaged at the beginning of the year by the prolonged drought, and the little left was further spoiled by the heavy floods which occurred towards its close, and, but for the abundant harvest gathered in 1883, there would have been a famine in many districts. The importation of rice from the neighbouring continent also prevented matters from taking a serious turn.

Coconut Estates too suffered greatly from the drought and large numbers of tender nuts fell off, which will go to decrease the crops this year. The price, however, of oil, copra, coir, etc., continued to be fair for some months, especially when the usual "bumper crops" in the middle of the year were taken in, and in a little measure helped to balance the losses occasioned by the failure of the paddy crops. The value of these articles soon fell and are now getting still lower. It is at this season (*i. e.* at the two last pluckings) that the out-turn of the nuts is generally *small* and with the low prices ruling at present, the loss to proprietors will be considerable.

Cinnamon Estates are not weeded as usual, and bring in little to the owners. The price of the spice is very low, and, when the peelers are paid 16 to 18 cents a lb. for their labor *alone*, the balance is inadequate to bear the cost of production, leaving out of consideration that the proprietors get little or no profit. Several large native owners have actually begun to root out the bushes of this fragrant spice and thus help on the old coconut tree, under whose shelter help never fails the cultivator. Of course, if the prices go up to an appreciable degree, there is still a chance for this product of time-honoured renown.

Fruit Trees of all descriptions gave handsome returns everywhere, and the cry was "Too much jak," "Too many mangoes," "Too many pine-apples," "Too many oranges," etc., from every quarter, and, owing to the great number of steamers, etc., coming to the harbour at Colombo, a brisk trade has been kept on for many months.

The Root Crops were fair; but of dry grain little has been cultivated since the forests in private hands are nearly exhausted just now, and the Government do not allow any "chenaing" on Crown lands.

It is yet too early to make a forecast of this year's "prospects," as cultivation of all kinds generally commences with the Sinhalese New Year, in April next.

TEA CULTURE IN CEYLON.

As regards tea cultivation in the new Kelani Valley district, we take the following from a communication to our local daily contemporary:—

"KELANI VALLEY CLEARINGS.

ACREAGE OF NEW ESTATES TO BE PLANTED MAY-JUNE, 1885.

Name of Estate.	*Acreage.*	*Owners.*
Pambagama	350 ...	J. Kinmond.
Yatiantota Co's Land ...	150 ...	Yatiantota Co.
Brasenose	60 ...	R. Aspland.
Wahakula	50 ...	G. L. Alison.
Total...	610	

"ACREAGE OF NEW CLEARINGS TO OLD ESTATES TO BE OPENED MAY-JUNE, 1885.

Nahalma	...	200	... Mackenzie Bros. & W. Forsythe.
Clunes	...	90	... Donald Cameron.
Lavant	...	40	... F. J. Wright & C.J. Inglis.
Kanangama	...	50	... Fairweather Bros.
Dewalakanda	...	20	... Mrs. Maria Reid.
Springvale	...	30	... J. F. Millington.
Kelani	...	60	... C. L. Davis.
Parusella	...	30	... R. S. Nisbet.
Wiragala	...	60	... E. P. Williams.
Total...		600	

"This makes a total acreage of 1,280 acres, but if I have left any clearings out, I shall be much obliged for the necessary additions at the hands of any of your correspondents. It will be noted that three or four estates have a very large acreage to open. The felling of 350 acres on Pambagama in one block and the planting up thereof will be no light work, and will tax the energies of its hardworking manager. The same may be said of the Yatiantota Co.'s 150-acre block. When we call to mind the fact that most of these low-country estates are, very properly, planted much closer * than estates at any altitude —sometimes as closely as 3½×3—some idea of the number of plants required for such a clearing as one of 350 acres can easily be obtained. About 4,000 plants to the acre would be required planting 3½×3, which for 350 acres would mean 1,400,000 plants, to say nothing of supplies. Pambagama is the name of that portion of the 1,000 acres applied for by Mr. Forsythe and withdrawn from sale by Government which was afterwards sold by Government to him on behalf of Mr. J. Kinmond, of machinery fame. It is about four miles north-east of the 37th mile-post on the Colombo-Ratnapura road, and about two miles south of the Deraniayagala-gange, with Nahalma a short distance to the north.

"Padda boats are moored to the side of the Kelani river (at Avisawala). One large boat was crammed with tea, and the well-known names of Dunedin and Dewalakanda were easily decipherable on the chests. Each boat holds, if I am not mistaken, about 10,000 lb. tea nett, and the cheapness of water transport may be inferred from the fact that the cost per lb. of tea to Colombo is about ½ a cent—R12·50 a ton. To give some idea of how heavy the traffic on the Kelani now is, enquiry as to the number of boats which passed up and down the river during a week elicited the information that from 16 to 20 boats made the double journey during that time. The up traffic appears to be quite as heavy as the down, all, or most of, the rice for the estates adjacent being brought up the river to Avisawella or Dehewitte kaddi-keepers."

CREATION OF SOIL.

The article we quote below from the *Straits Times* on the great Chasseriau estate near Singapore, is interesting, but we do not quite understand what is said about there being no soil, and soil being created by the action of rotting weeds and the ashes of stems of cassava on felspar. All the ingredients mentioned are constituents or products of the existing soil. It is described as gravelly, but our recollection of it, (and Mr. Chasseriau described it as fairly typical of the soil of the Malay Peninsula in general) is that it was a yellow-coloured clay. In this soil cassava grew splendidly, but coconut palms refused to fruit and were cut down when fourteen years old. The market for tapioca, being overdone, the enterprizing Frenchman turned his attention to Liberian coffee, which seems to flourish and to be, as yet, unattacked by leaf disease which, however, exists in the Straits, and will yet shew, we fear that it can do great harm, even to the gigantic coffee. If our good friend M. Chasseriau will take the advice of one who has a grateful recollection of his courtesy, he will "go in" for tea. He might also try cacao. We know he attached much importance to the mode in which he utilized weeds as manure, but he did not to us profess to "create" soil by operating with decayed vegetable matter and ashes on felspar, the felspar being, no doubt in the soil.

A VISIT TO CHASSERIAU ESTATE AT THE STRAITS:

COFFEE CULTIVATION—TAPIOCA.

(From a Correspondent).

I had heard (to my mind) marvellous reports regarding coffee cultivation on the island of Singapore; "two tons an acre was nothing, even as high as three tons was possible," &c., &c.

As we in India consider 7 cwt. an acre a good paying crop even at the present low rate, (I have known patches in a plantation carrying a ton), it was with feelings bordering on disbelief, to say the least, that I heard the above statements, which determined me to see for myself. By the kindness of a friend, I was introduced to Mr. Le Chasseriau, who invited me to come over and see the Chasseriau Planting Company's Estate. As I am interested in a Planter's paper, and therefore, to some extent interested in planting, I gladly availed myself of the first opportunity, fully determined that if my visit bore out what I had heard, there was hope both for the Ceylon and Indian planter. If land similar to what one sees here can produce such crops, surely the virgin soil of the Wynaad should produce better, and the worn out soil of Ceylon might again be made productive. Mr. C. received us courteously, and after a delicious cup of coffee (not his own growing) my friend left, and I was taken round the plantation. The first thing that strikes a visitor from India is the apparently high state of cultivation, each field a nursery, and each tree a *show* one. Having inspected the small field of about 12 acres, I was taken to another at the back of the house; here again was the same system of cultivation carried on, and the field from the distance forcibly reminds one of a young cinchona more than a coffee plantation; it must, however, be remembered that the coffee is Liberian, and not Arabian; the trees are not "topped" as in India; the lower branches are removed; therefore, it will be seen, one might easily, at first sight, mistake the fragrant plant for the bitter and nauseant one. It was difficult to realize how land composed to a great extent of felspar can produce such magnificent growth in such a short space of time (14 months), and naturally I was prepared to hear large sums had been expended in fetching soil from a distance as well as the free use of large quantities of manure. On asking for information, I was told, "the soil is lying at our feet; all that is necessary to produce it is common sense and a little practical knowledge." Being deficient in both, I asked for an explanation, and was made acquainted with the method adopted on this estate for the production of soil suitable for coffee. It is not generally known that felspar in combination with other substances is admirably adapted for a manure, and the way my friend proceeds to work is as follows:—The rapid growing grass and weeds on the ground are cut and heaped in combination with felspar; this is allowed to rot, and the process depends much upon the weather; if it is constantly kept wet, the longed for result takes place in a few days,—if not, probably weeks are necessary; as soon as the grass is thoroughly decomposed and dry, it is broken up and crumbles into small pieces, and you have your first ingredient. In connection with the estate is a large plantation of tapioca; this is a rapid growing plant, and in consequence contains large quantities of potash in the stalk. Tons of these are collected yearly, are heaped and burnt, the result being your second ingredient. These two are mixed in equal proportions, to which is added a small quantity of animal manure, and the pit, 2½ by 2½, is filled with the mixture, and a soil admirably adapted for the purpose is actually produced at a nominal sum. Practical results are worth any number of theoretical ones, and there is little doubt that the experiment now under review is in every way a success. If 500 acres can be opened and kept up in the same manner that the 90 acres now under cultivation are, there is little doubt but the Company will realize the fondest

xpectations of the most sanguine shareholder. The Liberian coffee in India bears but 2 crops in 3 years—here it is flowering the whole year. The 18 months old trees on the estate are loaded with fruit, and I understand the average yield from 5 year old trees is 18 lb. of dry parchment coffee yearly. The trees are planted 10 feet by 10 feet apart, which gives about 400 trees per acre, and if this result is obtained from 500 acres, (the proposed area to be opened) it is easy to understand that the estimated crops and marvellous tales one hears are rather underrated than overstated. There are most important questions that will at once strike the Ceylon planter—viz. are the forementioned results likely to continue, or will the "*leaf*," "*Bug*" and poverty of soil, eventually prove too strong for the plant. Taking them in their reverse order, the poverty of the soil is I think decided by the fact that there is no natural soil, and as long as it can be artificially produced and used as before stated, there is no fear on this point. It has been conclusively proved that Liberian coffee at least can stand "leaf" disease to a very great extent, and the last *bugbear* of the planter is not known in the island; and in a light gravelly soil such as we have here, with hot sunny days throughout the year it is not likely to be introduced; besides, there is a remedy for "*Bug*," even if it should appear. It must be borne in mind that we are dealing with Liberian, and not Arabic: the market value of the former is not so high as the latter by nearly 20 per cent, still the firm believers in the larger berry assert as soon as it becomes known at home, a demand will be readily created, and the price will reach and probably exceed that now given for the smaller, and, to my mind, more aromatic berry. This may be so, but time alone can show. One thing is certain, prices may go down to half their present low quotations. Get but 9 lb. per tree per annum, there will qe a very fair result shown. Labor is another question that presents itself to planters from India and Ceylon; the former probably does obtain labor at least 30 per cent eheaper than here, but then the means of transit from the plantation to the Coast (in many cases 100 to 150 miles) by means of country carts, would equalize the labor question. Then, again, the hours here for labor are at least toree hours longer than we can get from our coolies in India, and this alone would cover the 30 per cent; so in reality one does not pay more, as would appear at first sight but actually gains. Taking these two factors, "Coolies and Transit," we find the cost of production less than that in Ceylon and India. UBIQUE.

—*Straits Times.*

THE TURBINE WATER-WHEEL.

Since its introduction into use, first in France, and then in the United States, the turbine water-wheel has appeared under many different forms, but none has met with so marked success and so fully met all the requirements demanded of a motor of this class as the one invented and manufactured by Messrs. James Leffel & Co., of Springfield, Ohio. This turbine, which is a double one, is very different from all that class that makes pretensions to be double wheels. In it we find a combination of two independent sets and kinds of buckets—one a vertical and the other a central discharge—each very different from the other in its principle of action upon the water, yet each receiving its water from the same set of guides at the same time. The water, however, is acted upon but once, since half the quantity admitted by the guides passes to one wheel, and the other half to the other one, the water leaving both wheels or sets of buckets at the same moment and as quickly as possible. These two sets of buckets are so combined as to form really but one wheel, both being cast in one piece and being mounted upon one shaft. Owing to this arrangement, there is admitted the greatest volume of water possible, consistent with its economical use, to a wheel of any given size, while, at the same time, the greatest area for the escape of water is secured. The surface of the wheel is thus reduced to a minimum as compared with the quantity of water used, the material loss due to friction being avoided. The water is admitted to the turbine by twelve vertically-set guides, which serve likewise as water-gates, they being so arranged that they can oscillate upon pivots placed near their centres. These pivots are secured in the plates between which the guides oscillate, the upper one of these constituting the covering of the wheel and supporting the upper end of the water wheel shaft through a sleeve and bush. The lower plate serves as a support for the lower end of the shaft and as a means of carrying away the water from the wheel to the tail-race. These plates and guides, as a whole, form a casing for the wheel, the water having no entrance except through the guides, when desired to operate upon the wheel.

Such, in brief, is the principle of the Leffel turbine, which recently has received certain important modifications and additions that still further increase its efficiency, and make it practically perfect. In fact, the durability of the wheel and casing is such that the entire amount of repairs called for at the large shops of the firm per annum is covered by a sum so small, in view of the fact that over 8,000 wheels are in operation, as to be scarcely worthy of estimation. The firm has, within a few years past, so arranged and systematized its process of manufacture that if any part of a wheel becomes broken through accident it can be at once duplicated on receipt of the necessary information. In short, the Leffel turbine has kept pace, from its first introduction, with the most advanced developments of mechanical science; and, for any purpose for which the power of water is employed, it may be safely guaranteed as having no equal in utility, economy, and durability. Its popularity and the greatly increasing demand for it have compelled the house to erect new and extensive works, fitted throughout with the most approved and expensive labour-saving machinery, especially made for and adapted to the proper manufacture of the various parts of the turbine. The firm is thus enabled to produce the wheel at the very lowest possible cost.

We would recommend those of our foreign readers who are interested in such subjects to address the house for a copy of its "Wheel Book," manual which is regarded by users of water-power as almost indispensable, since it gives a full description of the apparatus, along with other information of the greatest utility.—*Scientific American.*

PLANTING IN THE PROVINCE OF COORG:

CLERK OF COORG WEATHER—ADAPTATION TO CIRCUMSTANCES—HIGH CULTIVATION.

MERCARA, December.—Ever since the famine year a new hand has been at the weather taps. It was not possible to keep on the old clerk of the weather after the fiasco of 1876-77, so he was deposed. The new incumbent is very zealous, but he is always trying experiments. No two years have been alike in its seasons since his reign. He gave us a deluge the year before last, and got into trouble about it. This year he tried a very mild monsoon, that threatened a famine, and then got nervous at the grumbling, and turned on the south east mousoon tap too strong, and thus flooded the country.* He seems still "irresolute," and keeps turning the tap on and off when he should shut off for good, and allow our weeds to die down, and our crops to ripen. Let us hope he will regain his composure soon. Fortunately our blossom showers were late, so our crops will be late also, which gives us time to carry on our war against weeds. It is wonderful how planters are adapting themselves to circumstances. When prices fell and advances were cut down to (in some cases) absuredly low figures, the unfortunates were in despair and said: "What can we do with such small advances; it was as much as we could do to get through with what we got last season." It is astonishing, however, how planters have found out, when they have set to work to it, how many works, and what amount of establishment which were hitherto considered indispensable, can be redneed and done away with. What a lot of fads have been knocked on the head; what a lot more real work a coolie can do; how much more reasonable are maistries, contractors and other blood-suckers; how delightfully slow the game of shell-out is going! A hundred rupees goes now where a thousand rupees would go last year.

I saw in the *Mail* that a planter in the Madulsima district in Ceylon had sent a specimen branch of new coffee to the Editor of the *Ceylon Observer*, who remarks that it

* North-east?—ED.

was a fair specimen of the crop on a field of 120 acres which has a crop of from 6 to 7 cwt. per acre. "The coffee, he goes on to say, "is ten years old and has had no manure." Now, high cultivation has been the cry of late. "You can't cultivate too highly," some successful ones have said. I don't say they are not right, but the axiom has been mischievous in its results. The only meaning it has conveyed to the bulk of planters is "You can't spend too much money on your estates." The one word "judiciously," which is the main secret, has been lost sight of. Men borrowed and spent in most cases injudiciously, and disaster resulted. The paragraph I have quoted proves that it is not necessary that a place is ruined because high cultivation is not carried out. There is hardly a planter who will not point out to you, as you go over his estate, a field with the remark "That,'s a wonderful piece; I have not given it a bit of manure, or done such and such a work on it, and look how well it is looking" or "look at the crop it has got." What I am trying to prove is this. There are many parts in every estate which, either on account of the soil, or the result of previous works, or some other cause, have got to a state In which they don't want any meddling; they will do as well without, anyhow for that year. Why waste your money, and bother them with your digging, your clean weedings, your centre pits, and your little handful of manure doled out so as to go so far as possible, impartially to good, bad, or indifferent parts? Here is an opportunity of saving with positive benefit. There are other parts, poor soil, blown and unshaded, which hardly pay the expensive work required for them. Yet, forsooth you waste money and time over them, because it would look unsightly to have semi-abandoned pieces in the middle of your estate. Here is another opportunity of saving without loss. Pass over those parts with perhaps the slightest of works. There are, again, other parts which are favourable enough in conditions, but are just out of their turn; they are resting or have received a check, or something small is wanting. A helping hand to these in good season would make them jump forward again. I say reserve your resources for these parts. Treat them liberally, and you will find at the end of the season that your place has not received so much damage after all, in spite of the stern withholding of the advance you thought you would require, and you begin to hope that after all you may some day call your estate your own.—*Madras Mail.*

TEA IMPORTS AND CONSUMPTION IN THE UNITED STATES.

The imports of tea, according to the Government returns during 1883, amounted to 74,799,919 pounds against 71,409,511 pounds for the previous year, or an increase of 4,390,408 pounds. The imports for December were over one million pounds more than the corresponding period of 1882. While the imports were so much higher than the previous year, the value was only $15,346,009 against $17,270,464. The imports for January, however, show a remarkable shrinkage, amounting to $6,386,958 against $9,629,529 for the same time 1883.

It will be seen that the consumption of tea per capita rapidly advanced after the duty was removed. While it was only 0·94 pound in 1867 it rose to 1·59 in 1881. Since that date, however, there has been a gradual shrinkage in the consumption, last year it amounting to only 1·31 pounds. The above years are calculated from July 1st to June 30th of each year.—*American Grocer.*

CHEAP QUININE.

To the Editor of the "Pioneer."

SIR,—There are many planters, no doubt, scattered in out-of-the-way corners of the mofussil, who may be interested to hear of the experience of a friend of mine, who lately purchased from a box-wallah, a bottle labelled "Produits chimiques—sulphate de quinine. Paris—one ounce." The price paid was R2. As the price seemed rather low, I thought it might be as well to examine it as to its purity, &c. I was prepared to find it a mixture of the alkaloids of the bark, but hardly for the result obtained. On analysis it proved to be entirely composed of hydrochlorate of cinchonia. Its appearance under the microscope was quite distinct from that of sulphate of quinine. In the price list of a wholesale druggist of London, when genuine sulphate was quoted at ten shillings per ounce, hydrochlorate of cinchonia was quoted one shilling and a penny per ounce. This shows a large profit for the fraudulent dealers. A simple test by which this article can be distinguished from sulphate of quinine may be made as follows:—Take as much as will lie on a two-anna bit, and dissolve it in 50 or 60 drops of boiling water; on cooling the sulphate of quinine will settle to an almost solid mass of fine crystals, while the hydrochlorate of cinchonia will remain clear, or give but a slight deposit. As the value of this substance as a febrifuge is far below that of quinine its substitution might in many cases endanger life. ANALYST.

THE DEATH OF DR. VOELCKER, F.R.S.

Planters in Ceylon and India, as well as farmers at home, will have learned with regret of the death of Dr. Augustus Voelcker, Consulting Chemist to the Royal Agricultural Society of England, which took place at Kensington on the 5th December, in the 63rd year of his age.

The deceased was the son of Frederick Adolphus Voelcker, and was born at Frankfort-on-the-Maine, on the 24th September 1822. He was educated at a private school and at the University of Gottingen, where he attained his diploma of Master of Arts and Doctor of Philosophy. Thence he removed to the University of Utrecht, where he became Principal Assistant to Professor Mulder and remained for some time under this distinguished Physiological Chemist. In 1849, he accepted the invitation of the late Professor Johnston to come to Edinburgh and superintend the Laboratory of the Agricultural Chemistry Society of Scotland, where his mind was specially directed to that branch of chemistry with which his name afterwards became so well-known. In 1851, he was appointed to the chair of Professor of Chemistry at the Royal Agricultural College, Cirencester, and there he instituted those carefully-arranged field experiments, the results of which formed the subject of many valuable communications to our agricultural and scientific literature, and which may be truly said to have laid the foundation of his future great reputation as a sound chemical adviser on all agricultural matters connected with soils, manures and feeding-stuffs, as well as the various productions of the dairy.

His private residence was distant about a mile from the College, and in the walks to and fro he had to pass over the principal portion of the model farm, so that he had daily opportunities of noticing the effects of the manures employed in the experiments, and, being a keen observer, he never failed to detect the effect of a change of temperature or a fall of rain. Students, young and old, flocked to Cirencester, not only to obtain valuable instruction in the laboratory and lecture-rooms, but also to see for themselves the practical results in the field. These eleven years passed in the bracing Cotswold hills were among the happiest of his life, and it was a matter of deep regret to his friends as well as a distinct loss to the students when, in consequence of certain differences in relation to the management of the College, Dr.

Voelcker felt compelled in common with three other Professors to resign his post in 1862.

It should be mentioned that, in 1855, he had been appointed Chemist to the Bath and West of England Society, and in 1857, upon the resignation of the late Professor Way, he became also Chemist to the Royal Agricultural Society, both of which posts he held till the time of his death.

Even upon leaving Cirencester and coming to London he did not abandon his field experiments, but with the assistance of old students and friends conducted them simultaneously in various parts of the country, and, being upon different soils and varying conditions of climate, the results obtained were all the more useful for comparison. Having established a laboratory at Salisbury Square, he devoted the whole force of a strong mind to the development of the interests of Agricultural Science, and the pages of the Society's Journal bear witness to his great activity in this important field of research. His reputation as a careful analyst and thoroughly impartial chemist made his certificate of the greatest value in the eyes of manufacturers, while his quarterly reports upon the analyses made for members of the Agricultural Societies were the means of checking the wholesale fraud and adulteration by which the unfortunate farmer was so often plundered in the early days of the artificial manure trade. As a lecturer, Dr. Voelcker was very popular at the numerous meetings of head farmers' clubs, and he was never more in his element than when addressing an audience of farmers, for, while imparting sound advice in plain, unaffected language, he always managed to introduce some amusing anecdotes by way of illustration. It was one of his favourite axioms, that, if you wished to obtain the confidence of farmers and lead them to believe in some new process which they did not understand, you should always first tell them some things that they already did understand. The quality which was perhaps pre-eminent in Dr. Voelcker's character was that of caution, and he therefore seldom committed himself to the expression of an opinion that was not based on careful observation or practical, experience, and, if he ventured to depart from this custom, his advice was accompanied with a caution that he was giving an opinion rather than stating a fact.

A hard worker himself, he naturally expected those animated with him should also be industrious as well as accurate in their analytical work; hence he preferred to employ paid assistants rather than avail himself of the gratuitous help of pupils. But he had a great objection to new faces in the laboratory, and most of those who were privileged to be associated with him in his interesting work remained for periods of from six to fourteen years a statement which speaks for itself as to his being a kind and considerate master, while it also indicates that the honor had to be limited to a few. Since 1877 Dr. Voelcker had conducted systematic investigations at the experimental farm at Woburn kindly placed at the disposal of the Royal Agricultural Society by the Duke of Bedford, with a view of testing in a different quality of soil the experiments which for so many years have been carried on at Rothamstead on the estate of Sir John Lawes. The current number of the Society's Journal contains his latest paper on the Chemistry of Ensilage, a subject at the present time of great interest to the British farmer. Some years since, he received the highest scientific honor in having the Fellowship of the Royal Society conferred on him. He was also Vice-President of the Chemical Society and of the Institute of Chemistry, a juror of the Fisheries and Health Exhibitions, member of the Council of the British Dairy Farmers' Association and honorary member of the Agricultural Societies of Hanover and Vienna. At the close of last December he had a stroke of paralysis and was granted six months' leave of absence from his official duties, but, after two months' rest, his longing for work made him disregard the advice of his friends and he was again in harness. During the spring and summer months he seemed much better though he never quite recovered from his attack.

In the autumn a change to the South of France was tried, but the period of relaxation had come too late, and the indications of general failure of health rendered an immediate return home necessary early in October. For two months he lingered, bearing a painful illness, with quiet resignation and simple faith, surrounded with every attention that a loving family and kind friends could afford. His funeral, which took place at Kensal Green on the 11th December, was attended by members of the learned Societies of London as well as by many leading agriculturists who during the Cattle Show week are always in time. Dr. Voelcker was one of the gentlest of men, and his simple unaffected manners gained him many sincere friends, while there are few country homesteads where his death will not be regarded as a national loss which it will be difficult to replace.

TEA PLANTING AND THE LAND MORTGAGE BANK OF INDIA.

The following are extracts from the report to be presented to the extraordinary half-yearly general meeting of shareholders.

The bank's liability on its current debentures now stands at £380,600, of which amount £49,360 is held by the bank, leaving a liability to the public of £331,240. Our debenture liability to the public on December 31st, 1883, was £353,100. It has been decreased during the present year by payment of drawn bonds to the extent of £21,860, and it will be further reduced on January 1st next by payment of drawn bonds to the extent of £10,440, thus placing it at £320,800, as against similar liability on January 1st, 1884 of £342,860. No fresh debenture has been issued nor has any drawn bond been renewed during the year. During 1884 we have sold six small properties in the Bengal Presidency for an aggregate of R47,750.

Tea.—Sufficiently accurate data whereon to base a reliable conclusion as to the total quantity of the Indian tea crop of 1884, or the shortfall in yield below the estimated quantity, are not yet available. The yield from the Bank's gardens in the Darjeeling district will be somewhat in excess of the estimated quantity, whilst the estimated yield from the bank's estates in Assam will probably be attained; but the Bank's estates in Cachar and Sylhet and at Kolabaree will show a shortfall to the extent probably of about 1,800 maunds, or 144,000lb. This shortfall is attributed to the prevalence of unfavourable weather during the spring and early summer aggravated by attacks of blight and red spider, and in the case of Jalingah by the destructive winds and hail storms to which we referred in our last report, involving a shortfall in yield of about 400 maunds or 32,000 lb. The plant at Jalingah has been carefully plucked and judiciously dealt with during the current season, and is reported to be in good condition for yielding well in 1885. Although in Assam and Darjeeling the Bank's gardens have made or exceeded their estimates, the weather has not been favourable for the making of good tea, and the run of leaf has been deficient both in sap and fine quality. Down to July our most experienced managers in Darjeeling expressed their inability to make teas of the usual character from their plucked leaf, and there has undoubtedly been throughout the season a general scarcity of fine teas from this district. The latter consignments from our Darjeeling lower division have, however, shown considerable improvement both in style and quality. several invoices from Moondakotee having realized sale averages of 1s 6d to 1s 9d per lb., whilst the last sale of Nagri teas produced an average of 1s 9½d per lb. Nagri was heavily pruned, over 150 acres during last cold weather, which induced the plant to make new wood freely, and though a large quantity of leaf was plucked it was inferior in strength and quality from a weakened flow of sap to the

leaf. We anticipate, however, that this plant will again produce much better tea next season. Our Cachar estates and those in our Lattakoojan division of Assam have contributed some breaks of really good and even fine teas, but their effect on sale results has been prejudiced by the lower quality of the larger portion of the outturn and the exceptionally depressed condition of the London market for medium grades and qualities. But for the unsatisfactory conditions under which our Cachar, Sylhet and Kolabaree estates laboured during a great portion of the season, our very moderate estimate of 21,970 maunds or 1,757,600 lb. would doubtless have been exceeded, and the increase upon last year's crop would probably have been 3,000 maunds instead of about 1,400, with which increase only it now seems probable that the season will close. Box-making has been successfully commenced at Jalingah and Shabazpore, and will next season be carried on in Assam, the supplies of suitable timber on these estates being considerable, and well adapted for box-making and general purposes. The particulars of each garden's estimated yield, realized crop and average sale price to latest dates during the current season, as compared with season 1883, are submitted on this occasion in tabular form for more convenient reference. Our latest reports from India testify generally to the good management and thorough cultivation of our various gardens, the healthy and promising condition of the plant, the satisfactory working of machinery, and the sufficiency of labour and all other arrangements and appliances. None of the current season's crop has been or will be sold in Calcutta, it having been deemed expedient to bring the entire crop to the home market. The principal features of 1884 operations in tea have been the continued fall in the value of Indian teas owing to increased supplies, and the fall off in the quality of the early Darjeeling produce from unfavourable weather. The fall in market value of Indian teas has probably been about 2d. per pound. The average price of our teas from Assam, Cachar, and Sylhet, have not fallen off to that extent, and it may therefore be assumed that there has been improvement in the quality of their produce.

The wish expressed by some of the shareholders at the last general meeting, that another practical tea planter should be asked to join the Board has not been lost sight of but we have not yet been able to give practical effect to the suggestion, the gentleman whose services we were desirous of obtaining being precluded from entertaining our proposal. In conclusion, we desire to express our regret that results should again have fallen short of our expectations.—*Home and Colonial Mail.*

COCONUT-MEAL AS HORSES' FOOD.—Can the following paragraph account for the demand for copperah in France of late?—"The French army has been experimenting upon the food of the horses. They report that a diet of oats mixed with coconut-meal resulted splendidly. The horses were not only speedily improved in condition, but the reduction in the cost of horse-keep amounted to 50 francs each horse per annum."

JAVA TEA.—The news comes from Australia of the arrival at Melbourne of a shipment of Java teas. It is said that the Java planters have determined to create a market for their teas in Australia, and propose to set about devices to "popularize" that article. This intelligence, says a contemporary, will hardly be received with satisfaction by the Indian tea planter who has been attempting for some years to popularize Indian tea in Australia.—*Pioneer.*

HALYCON DAYS FOR PLANTERS AGAIN.—Latest advices from South Travancore say that the Planters in the Ashamboo and southern ranges are going to have a visit of the good old times again. Coffee where cultivated comes on astonishingly well, and a good crop is expected this year. Every thing is prospering, but some time will have to elapse before any profit can be realized owing to the fall in the price of coffee at home.—*Madras Mail.*

IT is stated that the coming semi-tropical fruit is the Japanese persimmon known as the Panarasche. It has been recently introduced into Florida, where it flourishes finely. It is about as large as a Bartlett pear, of golden color, sweet, juicy and delicious. It bears transportation well.—*American Grocer.*

KELANI VALLEY, CEYLON.—The land appears, as far as the eye can reach, to be of very similar character as regards soil and natural growth—more so than land at a high attitude usually is. There we have heavy jungle with splendid soil alternating abruptly with poor patana. Here in this valley none looks so poor as upcountry patana or so rich as the heavy jungles of a higher altitude. But the soil, though poor in many parts in some is fairly good, and throughout there appears to be that irony color and tinge so good for tea. All the best hollows, where the wash from the hills has settled the richest soil at their base, belong to natives unable as yet to turn them to the best account.—*Cor.*, Local "Times."

SOME OF THE SAVANTS ARE INVESTIGATING ELECTRIC INSECTS.—Gen. Davis, of the British Army, who was a famous insect collector, once picked up a "wheel bug" in the West Indies, and received a shock which paralyzed his arm. On shaking the insect off, he noticed six red marks on his skin—the impression of its feet. This particular bug is now being studied closely. Some of the luminous beetles are found to be very electric, and one investigator, upon taking up an unknown caterpillar in India, received such a shock that his entire left side was paralyzed, and he remained for a long time dangerously ill.—*American Grocer.* [We doubt.—ED.]

THE AMERICAN EVAPORATOR AS A TEA DRIER.—Messrs. W. H. Davies & Co. of Colombo have received the following satisfactory reports of the performances of the American evaporators as tea driers:—Extract from a letter from Mr. J. H. Barber, Blackstone Tea Estate, dated 4th January:—"Thanks for the Thermometer. I had to postpone my experiments till I got it. I gave the Evaporator a patient trial today, and am happy to say with great success. *It will do very well as a drier for small gardens.*" Extract from a letter dated 5th January from Mr. W. Zeigan, proprietor, Citrus Tea Estate:—"I have tried the American Evaporator, and it is with pleasure I have to inform you that it performed its function as a Tea Drier in every way most successfully. The construction of the stove leaves nothing to be desired.

ORIGIN OF ANNATTO.—This colouring matter, so largely used for colouring butter and cheese, occurs in the annatto tree, *Bixa orellana*. The fruit capsules of this plant contain a large number of seeds embedded in reddish-coloured pulp. The colouring principle itself, *annattoine*, is obtained by macerating this pulp in cold water. It is largely employed at the present time for dyeing and printing woollen and cotton goods, the colour being fast and of a fine tint. Basket or a paste annatto is prepared in the tropical countries by placing the seeds of *B. orellana* in large vessels of water, and converting the whole, by prolonged heating, into a thick paste. By this process the brilliancy of the colour is much impaired, so that "basket annatto" cannot with advantage be used for dyeing fabrics; also cheese coloured with it gradually fades. The colouring matter is used by the natives of Brazil to flavour their food.—*Burgoyne, Burbidges, Cyriax, and Farries' Monthly Export Prices Current.*

MESSRS. MASSEY & COMPANY'S "INDIAN RYOT PLOUGH" was awarded the first place at th ploughing Exhibition held at Kaity last week. This plough has only just been brought out by them in view to supply the wants of small land-holders, and the poorest description of cattle. Judges were of opinion that if a competent person had worked the Indian Ryot plough, nothing in the Exhibition could have equalled it. That it did the best work could be seen at a glance—turning over much more earth than any of the others. Messrs. Massey and Co's C. P. Patent Pipe plough for dry cultivation, a very light all-iron plough, which has taken all the prizes up to date, obtained at this Exhibition only third honors.—*Madras Mail.*

CHRISTMAS FESTIVITIES IN THE TEA TRADE.

One of the most brilliant and enjoyable gatherings of the season took place on Monday evening last, when the Worshipful Company of Tea Tasters entertained a large and representative company at dinner in their splendid hall in Tea Lane. The entrance-hall and staircase landings were decorated with a rich profusion of tea shrubs in full flower from the establishment of the Messrs. Cooper at Earl's Court.

The Master said: He was proud to see before him gentlemen connected with almost every interest that had to do with tea, from the planter to the consumer. He thought that a friendly interchange of views and opinions might be of great benefit to all parties. Much that was said and done in Mincing Lane would lead an outside observer to think that there was more or less animosity between the different branches of the great tea industry.

How, for instance, could the broker or dealer expect permanently to succeed unless tea planting were in a prosperous state? Outspoken folks in Mincing Lane were never tired of crying out that the tea planter of today was by no means so thoroughly up to his work as he was twenty years ago; that now he only half-withered his leaf, and overfired it; in short, that his aim was to get his work quickly done, and out of his hands, utterly regardless of whether it had any keeping quality in it, or whether it would in a few months time go perfectly flat and stale. Mincing Lane was not always just to the planters, although it must always be admitted that its opinion had a market value which they could not ignore. In conclusion, he begged to propose the toast of "Success to the Worshipful Company of Planters," coupled with the name of the Master, A. T. Plant, Esq.

The Master of the Planters' Company in rising to respond, returned thanks for the kind manner in which his Company had been spoken of. Great advances had been made since he first went out to Assam in the year 1860. Tea planting was then partly of the nature of an experiment, now it was a great accomplished fact. With regard to Mincing Lane he had always gone his own course, and paid no attention to anything that was said there. What did "the Lane" know about tea planting he would like to know. Young boys, fresh from school, paid a premium to get into a brokers's sale-room, and after a couple or three years spent between tea tasting and billiard playing, or looking on whilst others played at either of these pastimes, came out to Assam or Cachar to teach planters what was, or was not, good tea. He admitted that it might occasionally be advantageous to learn from a man of practical experience as to what was likely to be the coming fancy of buyers in the home markets; but he contended that planters could easily arrive at the information by watching how their own produce sold, and varying it according to the prevailing demand. He complained that the prices realized for Indian tea in public sale were sadly inadequate, and blamed the selling brokers for permitting the buyers to combine together for the purpose of securing large breaks under the value, and dividing them out afterwards. He also thought that there was great room for improvement in the management of the bonded warehouses in London. He counselled his brother planters to remember that tea was made to be used as an invigorating beverage, and that they failed in their duty if they allowed considerations of leaf or appearance to tempt them to forget the teapot of the consumer. Indian tea had earned a wide-spread celebrity for its strength, which neither China nor Java had yet been able to compete with, and he trusted the day was far distant when they would allow themselves to be betrayed into a competition with either of those countries in the production of what is called "tea for price."

The Master then referred at some length to the imports of tea into the United Kingdom, and quoted statistics to show what an enormous increase had taken place in the consumption per head of population. He could not but regret the very unsatisfactory state into which tea importing as a business had fallen. Undue trading on credit, and over-supplying the home market during the summer months, when buyers were away on holiday, were two causes of much evil to the trade. He then went on to notice the very practical remarks of the previous speaker in regard to delays in delivery of tea from bond being due to its being sold before it was ready. Opinion was very strong in some quarters that the "prompt" should date from the delivery of the weight notes, and not from the day of sale, as at present. They were honoured by the presence of several large importers of tea, and he gave the toast of "The Importers of Tea," coupled with the name of A. Briar, Esq.

Mr. Briar rose to return thanks on behalf of himself and his brethren, although he admitted that as a rule he was not in the habit of consulting them on matters of procedure. He totally dissented from the opinion that delays in getting delivery of his tea from bond arose in any way from failure on his part. He admitted that some importers printed tea for sale before the ship had arrived, but as a rule he wished his tea to be weighed and ready before the catalogue was issued. He had no no doubt but complaints of delays were very frequent with other importers' tea, especially when protective theories were followed; but he had always endeavoured to carry out the policy of—No protection, No reserve, and No profit. Still, for pure philauthropy he continued to work on, and hoped no one would follow his example unless they were prepared to sacrifice everything, and incur the ill-will of all opponents.

The Master again rose and expressed his great gratification at the free and open manner in which the various speakers had responded to his call. There was yet one department, and an important one, too, which they would be pleased to drink success to before they separated, namely, the Tea Dealers' Company, coupled with the name of the Prime Warden, Sir Robert Sedgwick.

Sir Robert said, on the subject of warehouse management he should say that the haste with which importers pressed their tea forward for sale rendered the work of the warehouse-keeper very difficult to do well. Bulking in many cases was very carelessly done. Complaints were frequently arising, which showed plainly that the old practice of inspection by the selling broker was now little more than a matter of form.—*Home and Colonial Mail.**

CINCHONA TRIMENIANA.—At a recent meeting of the Linnean Society, a paper was read by Mr. E. M. Holmes on *Cinchona ledgeriana* as a species. The author expressed the opinion that under the name of *C. ledgeriana* a number of varieties of forms, and probably some hybrids of *Cinchona calisaya*, are now under cultivation in the British colonies. He believed that if more attention were paid to the characters afforded by the bark of the trees, taken in conjunction with the other botanical characters of flower and fruit, these varieties and hybrids would be more easily defined and recognized. He considers that the plant published under the name of *C. ledgeriana* by Dr. Trimen was probably referable to Weddell's *Cinchona calisaya*, var. *pallida*, as a horticultural form, for which the author proposed the name "Trimeniana."—*Athenæum.*

CONCRETE WALKS.—An engineer tells how to make a cement or concrete walk requiring no great skill in preparing materials. These are water, lime and gravel or ashes, or both. The gravel and ashes are put in a heap and wetted. One barrel of the water lime is mixed with sharp, clean sand, dry, being shoveled over back and forth several times to get a thorough mixture. A portion is then mixed with water into a thin soft mortar and five parts of the wet gravel or ashes are well mixed with it, so that every fragment is coated with the combining mortar. This is important for obvious reasons. This concrete is spread on the graded walk and beaten down with a rammer until the moisture gathers on the surface. Some of the dry sand or cement is then scattered over the surface to absorb the moisture, and the surface is smoothed over with a plank rubber having a sloping handle to work it back and forth. In a few days this is hard and becomes harder with time. By making divisions of thin strips of wood or tarred paper the cement may be laid down in blocks, squares or diamond shaped, and for extra good walks the blocks may be colored by mixing the finish coat with brown or gray or other colors alternately.—*Florida Dispatch.*

* Our readers will, of course, detect the imagination involved in this Christmas report.—ED.

TEA CULTIVATION IN THE PUNJAB.

Tea cultivation in the Punjab is making steady if not rapid progress. In 1883 there were 1,894 tea gardens in existence, showing a slight advance on last year. Only forty-four gardens out of the total number are "European plantations," the remainder being worked and owned by natives. The total area under cultivation is returned as 9,056 acres, of which 5,708 acres and 2,256 acres represent the area under mature and immature plants respectively, and 1,092 acres the area taken up for planting but not yet planted out. Compared with the previous year there was a falling-off of 1,020 acres under tea cultivation. Several of the larger plantations show a considerably reduced area in the returns, but no reason is assigned for this reduction, and it is therefore supposed either that a portion of the area originally taken up has been abandoned as unsuitable for tea or has been appropriated to other purposes. In 1883 the total outturn of tea was 1,300,000 lb., of which 984,405 lb. was black tea and 315,605 green. Of the total outturn 899,957 lb. was the yield of the European plantations and 400,053 lb. that of the native gardens. Compared with 1882 there was an increase in the outturn of 81,491 lb. The increase is due to the European gardens, and occurred chiefly in the manufacture of black tea. The average yield per acre of mature plants was 209 lb.,—257 lb. per acre on European plantations, and 147 lb. on native gardens. The cost of cultivation per acre was R64-4-0 for European gardens, and R27-9-0 for native, while the cost of manufacture per lb. was 4 annas and 3 annas respectively. Some explanation is given as to the manner in which the cost of manufacture has been arrived at. As figures for about half the number of plantations were not available, those of the larger plantations were taken, and an average was struck from them. The result obtained was R0-3-3 per lb. This, however, was raised to 4 annas on including the cost of manufacture per lb. on European gardens. The area under mature plants has been enlarged during the past year, but that under immature plants is stationary.—*Englishman.*

HURRIALLEE GRASS.

TO THE EDITOR OF THE MADRAS MAIL.

SIR,—With reference to a para. in a late issue of the *Mail* on the Hurriallee Grass Seed for Australia, allow me to state that the word Hurriallee is a corruption from Dukuee for *Hariyaghaus* or green grass: *Hariya* green, and *ghaus*, grass; and this name is now popular in English for the *Cyno-dondactylon* of Persoon. *Panicum dactylon* of Linnæus and Roxburgh, and *Agrostis linnearis* of Ketz. In the vernaculars, in Tamil it is known as *Aryampilloo*, in Telugu *Gericha Kasavu*, in Bengallee *Durva*, in Urdu *Dub*, and in Sanscrit *Durva*; and it is not only one of the commonest and most abundant of grasses, but it is the most nutritious and useful on which our horses and cows are fed in most parts of India for the greater part of the year. It is exceedingly abundant in all natural and artificial grass lands in this country, and is admirably adapted for permanent pastures, and on a lawn, roadside or tank bund, is the prettiest and most lasting grass. When well-grown, it attains from 10 to 18 inches in height by its branchlets, whilst the culms creep underground, rooting at each joint, and throwing up fresh shoots; thus it spreads far and wide. It is celebrated by Hindu poets, and is held sacred to Ganesha, and is universally known and recognized. In arid soils a few of the dwarfed leaves are only to be seen in clumps, whilst the succulent culm keeps underground, and it is these roots and culms that the Madras grass-cutter produces for our horses; whilst, when irrigated and manured, it attains to 18 inches or more in height, and furnishes from five to six crops during the year; when cultivated for hay, with its long linear leaves, it is seen at its greatest beauty. The natives use the roots in medicine; its action is supposed to be diuretic; the tender leaves are used as medicine also. A native clergyman once brought the leaves of this grass to me as an antidote to snake poison. So confident was he of its success that he was willing to stake his reputation on it, and, need I say, that he went away sorely disappointed at its non-success. Dogs are fond of the tender grass, which they readily eat, and hence it is called by some people "Dog Grass." It is the principal of Indian grasses, and seeds freely; the seeds are small, and birds are fond of them. They are collected and sold by seedsmen in Bangalore, but as collecting them requires much care and trouble, they are rather expensive to purchase. JOHN SHORTT.

ENGLAND AS A MARKET-GARDEN.

In an interesting eight-page tract, just issued by Government, it is shown that in 1882 no less than over thirty-eight million pounds sterling of articles of food for man and beast were imported which might have been grown in this country; and so, on an average, £1 per acre might have been added to the total acreage of the cultivated land of England. The return alluded to, entitled *Customs Statistics for* 1882, gives the following details of imported articles:—

Animal Food:—	
Bacon and hams	£7,772,063
Poultry and game	583,797
Butter	11,350,909
Cheese	4,749,870
Eggs	2,385,263
Lard	1,866,360
Vegetables:—	
Chicory	94,750
Hops	2,962,631
Onions	527,781
Potatoes	997,120
Tares	134,994
Vegetables unenumerated ...	416,409
Fruit:—	
Apples	783,906
Nuts	442,570
Fruit preserved without sugar ...	146,476
Do., raw, unenumerated	1,415,252
Do., dried, unenumerated ...	147,987

Of course there is an obverse view of the pecuniary plenty consequent on such extended market-gardening. Practical fruit-growers have called attention to their seasons of disappointment and low prices, as well as their years of plenty. The strawberry-growers of Blairgowrie, whose achievements have won notice from Mr. Gladstone, complain this season that the price of their staple has been such that it does not yield a profit. Jam-making appears to have been over-pushed. The colony of forty industrious proprietors on land that previously was only capable of pasturing travelling flocks going or returning from the Falkirk Tryst appeared to us on a recent visit one of the social features of the time. But the colonists are grievously handicapped by the proprietor, owing to a heavy feu rising to £5 per acre of their two to four acre lots and the necessity of immediately erecting a house to the value of £300 or so on the same.—*Journal of Forestry.*

PYRETHRUM.

The following notes concerning this insecticide were communicated by Prof. A. J. Cook, of the Michigan Agricultural College, to *Gleanings in Bee Culture*:—

"Pyrethrum is a generic term referring to the powdered flowers of one of three distinct plants—*Pyrethrum roseum*, *P. Carneum*, and *P. Cinerariæfolium*. The powder from the two first-mentioned plants is known from the locality where the plants grow, as Persian insect-powder, and for a like reason the latter is called Dalmatian insect-powder. Buhach is the Dalmatian insect-powder that is grown and manufactured in California. G. N. Milco, of Stockton, Cal., who, I believe, is a Dalmatian, has given the name of his product—buhach—to protect him against the adulteration which is quite sure to overtake so valuable an article. This powder owes its valuable properties to the presence of a volatile substance which, unless the powder is kept close, will escape, when the article is valueless. Buhach, which I have had a year, and have kept in a close tin vessel, is not so effective as last year, nor so effective as fresh powder obtained this year; yet it kills most insects to which it is applied. Another peculiar property of fresh pyrethrum is that it may be mixed with several parts of flour, and still be potent to destroy. This makes adulteration easy, and likely had its influence in causing Mr. Milco to adopt a peculiar name for his product.

"Buhach—indeed, all pyrethrum—kills by contact, and

not by being eaten. Again, it is entirely non-poisonous to vertebrates. A friend told me that he ate a tablespoonful with no harm even to his digestion.

"I have found the powder very effective to kill many insects, when dusted on to them by use of a dust-bellows, or sprayed on to them when mixed with water—one tablespoonful to two gallons of the liquid—by use of a Whitman pump or when the alcoholic extract is applied as a spray. We kill our house-flies, by dusting on the powder. We do this as we retire at night, and can sweep up the dead or paralyzed flies the next morning. I prefer to kill cabbage-worms, slugs, etc., by spraying with the liquid mixture. I have not seen the article you mention, so cannot say as to the correctness of its representations, but I do consider pyrethrum a *very valuable* insecticide, especially the buhach, which is more apt to be pure and fresh. While many of our worst insect pests are quickly killed by use of this powder, I have found that some bugs and a few beetles are proof against it. In all our use of this substance, when dusted into close rooms like living-rooms or chicken-houses, the dust comes in contact with flies, lice, etc., and quickly kills. We must put it immediately on the insects, as its virtue is soon gone."

It is a common practice of dealers to keep this powder in open boxes or barrels, but it is evident, from Prof. Cook's experience, that pyrethrum so kept must soon lose its active properties.—*Farm and Fireside.*

ASSIMILATION OF MANURES BY THE SOIL.

BY SIR J. B. LAWES, BART., LL.D., F.R.S.

In a previous article I pointed out that when a soluble salt of potash, or a soluble phosphate, was applied to the soil, plants which required these substances could take them up in large quantities, but that in the course of time they became fixed in the soil, and then were not so readily taken up by plants.

In some of our pasture experiments we apply annually 500 lb. of sulphate of potash per acre; two crops of hay are removed each year, and when the season is favourable, the crops carry off more than the whole of the potash contained in the manure. Of these two manures it may be said, therefore, that when first applied they are readily taken up by plants, and if not taken up at once they form fixed compounds with the soil, and remain at the disposal of vegetation for very long periods of time.

With regard to the various compounds of nitrogen, we can find no simple formula which can be applied in a similar way. It may be said of ammonia, as it exists in salts of ammonia—and possibly of ammonia in all forms—that the process of its nitrification goes on in the soil in the absence, and quite independent of, vegetation growing on the surface, and that the nitric acid formed is—in the absence of vegetation, or unless taken up by vegetation—washed out of the soil.

Nitrogen in the form of ammonia, or nitric acid, and more especially in the latter form, is of the greatest possible importance from the fact of its furnishing our crops with their chief, if not their sole, supply of this substance, but at the same time it constitutes but a very small amount of the nitrogen which exists in our soils or manures. Nitrogen in combination with carbon, or what is generally termed organic nitrogen, is the main source of fertility, and in the form of cattle food, manures, farmyard dung, bones, and similar organic compounds, it will constitute one of the chief items in the tenant's claim for unexhausted fertility. To separate the landowner's organic nitrogen from that of the tenant, and not only to assign to the latter the proper amount of his organic nitrogen, but also to fix the period at which it will assume its active form, will constitute one of the chief difficulties of those who undertake the responsible office of arbiters.

The period of time at which we may expect a substance applied to the soil to form part of the crop appears to be full of difficulties. We have recently been making some investigations in regard to the rate at which nitrification takes place in soils and subsoils, and we find that some of the leguminous plants have roots extending 5 or 6 feet, and even in some cases more than that, below the surface. We find, further, that organic nitrogen, as well as nitric acid, is to be found at these depths; it is evident, therefore, that the large amount of nitrogen which these leguminous plants take up, even when grown upon soils where cereal crops would find very little, may probably have its source at the same depth.

My observation leads me to think that organic manures, and such manures as potash and phosphate, descend slowly into the subsoil, and are in some degree out of the reach of the ordinary roots of plants, except when special climatic circumstances favour the extension of the roots of wheat and grass into the subsoil; and I can always calculate on a large growth than usual of these plants in the experiments where the surface soil has been purposely exhausted of its mineral food. The descent of manure into the subsoil proceeds very slowly, and even where we have applied 14 tons of dung per acre annually for forty years, the second 9 inches of soil contains comparatively but a small amount of increased fertility.

It is the practice of gardeners to place the manure in a trench between 9 inches and 18 inches from the surface, and thus ensure subsoil fertility. The second 9 inches of my garden soil, which has received no manure for more than thirty years, and during that period has grown about one hundred large crops of red clover, is still very rich in nitrogen. It is evident, therefore, that to exhaust a soil of its accumulated fertility is not so easy a process as many would suppose, even on agricultural soil, as in the ordinary practice of agriculture to get the land into condition, and then to remove that condition, occupies the larger portion of a nineteen years' lease.

The Agricultural Holdings Act was passed in order to prevent the necessity of this reduction of fertility. The Newcastle Farmers' Club has boldly attempted to grapple with the question of compensation by valuation, based upon the manure value of different goods, while the Chamber of Agriculture and Clubs in other countries propose to contract themselves out of the Act by the payment of a certain portion of the cost of the food. This latter process appears to be much more likely to lead to litigation, as although such an agreement may be made, it is only to be binding on the condition of its being fair and reasonable. Possibly some day the fact will be recognised that the cost and the manure value of goods have no necessary connection with each other, and then some landowner or incoming tenant will require to be bound by the agreement.—*N. B. Agriculturist.*

COCONUT PRODUCTS.

The paragraph we extracted in our last issue from the *Observer*, regarding the fattening of horses on coconut meal in France, was inadvertently published without our remarks. Our contemporary, in referring to the success of the experiment of feeding up horses with the meal inquired, Can the demand for Copperah in France be due to this fact? Probably it is, but we fancy the chief reason why Copperah is in demand on the Continent is for the oil for Soap Manufactories. Perhaps few have noted the extent to which the exportation of Poonac itself has grown in recent years. Mill Poonac used to be almost a drug in the market, as cart drivers and others preferred Chekku Poonac for their cattle, owing to its containing more oleaginous, that is nutritive matter. Mill Poonac, from which a larger percentage of Oil had been extracted by more effective grinding and greater pressure, was chiefly used locally as a manure, and the demand for export was almost *nil*. We believe Mr. Alexander Stevenson maintained for a long time the fertility of his Dimbula properties by manuring them with unlimited quantities of Poonac from his Kelani Ganga Mills. His Firm now exports the better part of the refuse which he used to send upcountry; and during a recent visit to the Hulftsdorp Mills, which we were enabled to pay through the courtesy of Mr. G. B. Leechman, we saw large quantities being packed in gunnies for export. The price at which the Poonac sells has more than doubled—R45 per ton being now the price, as against R20 in former years. According to the Customs Returns for 1883, over 40,000 cwt. were exported that year, France taking the largest quantity, viz., 18,169 cwt. We have little doubt that most of this Poonac is used in the preparation of cattle food, and in the feeding up of horses, although we have heard that the voyage transforms some of it to linseed meal as well! The market for Poonac

has been steady for some time past, and there seems no reason to expect a fall.

The demand for Copperah too has grown, and very satisfactory prices have been realized, good qualities securing an advance of as much as R5 per candy over the prices which the Mills can pay. Of Copperah, as of Poonac, France takes a very large share, our best customer being British India. The residuum of Poonac which all this Copperah when expressed must leave, is, no doubt, put to the same uses in Europe as the Poonac which is imported direct; but we suspect it is the large quantites of Copperah we have exported, which has helped to slacken the demand for oil, and to lower prices; for we have now to take account, in addition to the largely increased exportation of oil, of the heavy exports of the material of which oil is expressed. Whatever the effect on the local manufacturers of oil, the proprietors of coconut estates have largely benefited by the competition for Copperah enchanced by export orders, and by the increased demand for Nuts too for export.—"Examiner."

PAPAW FRUIT AND "PAPAIN-FINKLER."

Professor Finkler, of Bonn, has furnished us with the following report:—

I have for several years turned my attention to the chemistry of digestion and ferments; it was, therefore, only natural that I should take an interest in Papain, which I find dissolves albumen and fibrine in acid, alcohol, and pure water. I test the whole of the Papain in my laboratory, and I guarantee that it will dissolve in pure water 1,000 times its weight of fresh fibrine.

This preparation is different to any other I have tested, because it is not acted upon by exposure to the atmosphere, and will keep for some time.

"Papain dissolves the membranes of diphtheria and croup very rapidly, not a single patient that I have treated in the University Hospital or in private practice has died, but all have recovered. In every case the membrane was dissolved by painting it with Papain about five times a day. In very severe cases, I have continued the application during the second day. I found that as soon as the membranes were dissolved the fever disappeared, and the pulse became normal."

Dr. Rossbach, Professor of the University of Jena, a very distinguished physician, has had the same results. It is evident that the danger of diphtheria is due to the membrane, and, if this is destroyed, the danger disappears. As Papain can be applied with salicylic acid, which increases its action, I maintain that there is no other drug in existence that has equal properties for this purpose. When using Papain to paint the membranes caused by diphtheria, I mix it with water until it appears like a muddy liquid. I never mix more than the quantity of Papain required for the one operation, as it appears that Papain loses somewhat of its power if allowed to remain dissolved for any length of time in water. Therefore every three hours I prepare a fresh solution for application. Papain cannot harm either the stomach or bowels. I have taken it myself in doses of 0·1 to 0·2 grams (1½ to 3 grains). I have prescribed Papain to a great many of my patients affected with disease of the stomach, but I have never known any bad effects. Even an atonic and also an anæmic stomach can take it without the slightest ill effects. On the contrary, an increased appetite is soon observed. Papain dissolves the mucous and cleanses the stomach effectually. It is not correct that Papain dissolves the lining (mucous membrane) of the stomach. I have given it to animals, and have observed, after having had the animals killed, that the mucous lining of their stomach was sometimes slightly reddened. If, however, Papain is given directly after meals, when the stomach contains food, I have never noticed a change in the appearance of the stomach. Acidity of the saliva is in most cases a consequence of deranged digestion of the stomach; by taking Papain, which causes an increase of the powers of digestion, the acidity of the saliva will cease.

The following difference between the action of Pepsine and Papain is important to note:—With or accompanying the activity of the saliva, there is an excess of acidity in the stomach. This can be removed by prescribing *Natron bicarbonicum* (bicarbonate of soda), &c., but as soon as the acid in the stomach is thereby decreased, the effect of Pepsin is paralysed, because Pepsin only acts when it comes in contact with a free acid. As, however, Papain digests either with an acid or alkaline reaction, although best in pure water, it is clear that Papain will decrease any acidity of the stomach or saliva, and promote a good digestion. This is an important point to bear constantly in mind.

The following information also proves the great value of Papain. Prof. Kühne, at Heidelberg, has substantially shewn that Pepsin is destroyed by the action of Pancreatin. It is not possible to have a simultaneous action of both these ferments. The Pancreatin joins the chyme—chymus—as soon as it leaves the stomach and enters the duodenum. Although the digestion is improved by adding Pepsine, the latter will only act during the brief period while the food is actually in the stomach. As soon as the food enters into the duodenum Pepsin is rendered powerless by the juice of the Pancreas, consequently Pepsin ceases to act whilst the food remains in the bowels. With Papain it is different, as its action will be increased by both Pepsin and Pancreatin, and the power of digestion by Papain continues to be exerted in the bowels. Pepsin cannot accomplish so much, especially as in many parts of the bowels the re-action is alkaline, and consequently Pepsin is rendered powerless.

As long as a regular digestion goes on in the bowels, there is no possibility of decomposition (rotting). Flatulency and similar complaints caused by any abnormal matter in the bowels will be prevented by the use of Papain.

I prescribe Papain in the form of a powder, which should be mixed with water in a spoon or glass. I give it either pure or mixed with natron *bicarbonicum* or a mixture with equal parts of *natron bicarbonicum* and *elæosarcharum menthæ piperit.* It should be taken immediately after meals. The dose is 0·1—0·3 gram=1½ to 4½ grains.

To cause an artificial digestion, I use clear water, not hydrochloric acid, because the creation of Peptons is thereby better accomplished. I consider as a most remarkable circumstance that meat soaked in Papain and water, or even moistened over with it, will not putrify (rot), but can be kept for days in a room without further care to keep it from going bad. On the other hand, meat moistened with water, without any admixture of Papain, and kept in the same room will rapidly acquire the bad smell and decompose.

THOMAS CHRISTY & CO.

[If it be true as stated that "Papain" (derived from the papaw fruit) cures diphtheria, then a very important discovery has been made.—ED.]

ORIGIN OF CULTIVATED PLANTS.

In the vegetable kingdom there are about 140,000 species of plants. Of these 247 are cultivated for domestic use. At one time, before the advent of man, these 247 plants existed in a wild state, and in the *Origin of Cultivated Plants* (1), Mons. Alphonse de Candole, a renowned Genevan botanist and member of Scientific Societies in all parts of the world, endeavours to trace when and where man set himself to propagate them for his own use. For this purpose very extensive and laborious researches have been undertaken. Various kinds of evidence had to be examined. Ancient history, ancient sculpture, and ancient monuments all helped to throw light on the subject; books of travel and botanical science afforded another means of defining the history of cultivated plants; while a third and very valuable source of information lay in a study of the comparative philology of plant names. To competently canvass all these witnesses as to the facts of the case in reference to each particular plant implied the possession of wide general culture, and Mons. de Candole may be congratulated on the success attending his work. More than a quarter of a century has been devoted to its careful elaboration. By patiently bringing together every little scrap of evidence, the author has succeeded in tracing the careers of what may be termed our domestic plants to very remote periods. Some of his assertions may be questioned on minor points, but the book may be taken as recording everything that is known or knowable in reference to the history of cultivated plants. To afford readers an idea of the results brought out, the following table may

be given. It refers to plants grown in the Old World, and column A represents species cultivated for more than 4000 years, according to ancient historians, the monuments of Ancient Egyyt, Chinese works, and botanical and philological indications; column B contains the names of plants cultivated for less than 4000 years, as indicated in Theophrastus, found among lacustrine remains, or presenting various signs, such as possessing Hebrew or Sanskrit names; while column C contains plants cultivated for less than 2000 years, *i.e.*, mentioned by Dioscorides and not by Theophrastus, seen in the frescoes at Pompeii, or introduced at a known date:—

A.	B.	C.
Turnip.	Radish.	Parsnip.
Onion.	Carrot.	Shallot.
Cabbage.	Beet.	Sea Kale.
Tea.	Celery.	Parsley.
Flax.	Lettuce.	Artichoke.
Hemp.	Asparagus.	Spinach.
Mulberry.	Leek.	Clover.
Vine.	Pea.	Jute.
Mango.	Indigo.	Hop.
Apricot.	Sugar Cane.	Raspberry.
Almond.	Orange.	Strawberry.
Peach.	Cherry.	Gooseberry.
Pear.	Plum.	Red Currant.
Apple.	Rye.	Black do.
Pomegranate.	Oats.	Coffee.
Water Melon.	Poppy.	
Cucumber.	Mustard.	
Olive.	Cotton.	
Fig.	Pepper.	
Date Palm.		
Bean.		
Lentil.		
Wheat.		
Barley.		
Millet.		
Rice.		

The discovery of the American continent brought a new set of plants within the reach of the Old World, but it did not add so largely to the list of cultivated plants as might have been expected. The following is a table of the principal cultivated plants introduced from America, and column D represents species cultivated in very ancient times; column E species cultivated before the discovery of America, but without showing signs of a great antiquity of culture; and column F species only cultivated since the discovery of America:—

D.	E.	F.
Sweet Potato.	Jerusalem Artichoke.	Quillia.
Coca.	Potato.	Crown Bark
Tobacco.	Guana.	Cinchona Bark.
Maize.	Pumpkin.	Virginian Strawberry.
Mushroom.	Sgrash.	Chili do.
	Prickly Pear.	
	Capsicum.	
	Tomato.	
	Pineapple.	

This list of new plants brought from America is very small, especially of those brought into cultivation since the discovery of America. The intelligence of the natives was sufficient to detect the good qualities of most of the plants growing in that continent. It is noteworthy that maize is the only substantial vegetable America has given us. Maize came originally from South America, and the northern portion of the continent has only supplied the Jerusalem artichoke and gourds as nutritious plants worthy of cultivation. Australia and New Zealand have been similarly scanty of additions to the vegetarian bill of fare. They have furnished only one tree of consequence—the *Eucalyptus globulus*—and only one vegetable, not of much value, the *Tetragonia*. This work goes far to prove that as regards obtaining bodily comforts from the vegetable world our ancestors were as clever as ourselves. The columns A and D include all the more valuable of the vegetable products, and no doubt many of the other articles might be added to these columns were additional evidence forthcoming. The author looks forward to a time when manufactories will take the place of corn fields, sugar cane plantations, and palm oil groves; but new plants will have to be cultivated to meet the wants of these new manufactures. On the present lines the vegetable kingdom is no doubt tolerably well exhausted, since the only additions that have been made in the Old World to our cultivated plants during the last four centuries are spinach, sinfoin, clover, and strawberries.—*Dundee Advertiser.*

BRITISH NORTH BORNEO.

BY A CEYLON PLANTER.

Chinese labor is very different, but one must not suppose that a Chinaman, even with the sweetest of flattering terms, will do for you what he will for himself. If he is to be paid by the day, a hour's work can be spread, manipulated, and eased out till a week is gone through; but if, on the other hand, John Chinaman is paid by the job, 5 in the morning will see him hard at work, and sunset will likewise find him still laboring, as if he had only just started. No praise is too great for the frugality of the Chinese. They waste nothing, and, where any other creature would starve, there they can make a living. As gardeners they are perfect. Every scrap of rubbish, offal, dirty water, and house sweeping, will find its way into a Chinaman's garden. If the weather has been too dry, long before sunrise will the Chinaman be up, watering each plant with the utmost care, and even at night I have found them working, while his more luxurious neighbor the Malay will be lounging in his room, while his wife plays with brutal force on an accordion some wild and fitful air that has an unmistakeable English sound in it, such as "We won't go home," or "Ring the bell, Watchman," all of which are blended with a Malay tune, and worked at, with unceasing variation for hours, and at *double* express speed. On one occasion I had four of these entertainments going on at once, all working with the most praiseworthy zeal to eclipse the next, as regards, I may say, brutality of execution. I complained to the Police next day! But to continue my subject, Chinese gardens not only are very wonderful, as regards works of labor, but the wonder becomes greater seeing the disadvantage in point of soil they have to contend with. Of course I am speaking with regard to the soil about Elopura itself, which is exceptionally poor. Clay is the chief characteristic, with a thin top soil that very soon washes away, as, mingled with it, is a fine sand.

The rocks about the place are all sandstone, of extreme softness; so much so that, in the beds of streams, one frequently finds scars made by the chafing to and fro of a branch that has been caught by the water. By way of compensation for poverty of soil, the climate is extremely forcing, being steamy as well as hot. The rainfall for the year is about 136 inches divided thus: January 22 inches; February, 14 inches; March, 6 inches; April, May, June, July, August, September, and October average 8 inches, the lowest being 5½ in April followed by a rapid increase—in November to 20 inches, and 22 in December—falling on about 190 days. The temperature too is very warm, the lowest in the shade being about 69°, and the highest a little over 90°. The heat, however, is very different to what we are accustomed to, as, to use an illustration of my own, one is boiled, and not baked. The coolest time in the 24 hours is a little before sunrise, when one feels exceedingly chilly, but unfortunately this does not last long.

Up to the time I left North Borneo but little land was in cultivation; and, what there was, I might say, was of an experimental nature, and making, perhaps, a total of 200 acres, not counting what had been abandoned. Tobacco appears to be doing the best of anything I saw in the Sandakan district, and, this being in the charge of experienced men, will doubtless go far to show what is to be the future of North Borneo.

Since the above was written a friend of mine writes from Borneo as follows, on the subject of tobacco:—"Tobacco is turning out much better than was expected, and the quality G—— says (and A—— agrees) at least is as good as best Delhi. . . . . We are getting up locally a company to start tobacco, and of which *officials* alone have already taken up 185 shares 100 dols. each, and we will have at least 350 shares of the 1,000 required taken up here. The row in Darvel Bay is all settled, the Company having taken over the bird's nest caves for 10,000 dols. a year and immediately, sub-let for 10,000 dols. per

annum. The Chief Inspector's last trip has resulted in completely quelling the turbulent hill tribes on the West Coast, and all of them have come in and asked to be allowed to pay poll-tax (at least another 5,000 dols. a year to Government), besides which the inland tribes behind the hills numbering over 15,000 who have all along been anxious to pay poll-tax, and to trade, will be able to do so; so that will result in other 15,000 dollars per annum, besides the duty on the native tobacco, &c., they export, and this made a general increase in trade (the hill tribes when they came down to give in their submission brought so much tobacco with them that the traders, not expecting so large a supply, were unable to purchase the whole of it, as their trade goods ran out). Altogether things look better just now than they have done for the last eighteen months." This alone shows that the soil and climate of Borneo are both adapted to tobacco, though our Ceylon products might not thrive there.

From what I saw, I do not think Liberian coffee will ever be a paying thing in Borneo, and, though individual trees with piles of fruit on them may be instanced in favour of its cultivation, yet the cost of production, the low value of the article, and above all the uncertainty of its continued growth and bearing, combine to make me think this branch of industry will never be a profitable one in the New Ceylon. Of Arabian, the same may be said, even though leaf-disease is unknown. I may mention in passing, that I took to North Borneo, with me, some Arabian coffee seed, Liberian and cardamom seeds, by way of experiment. In its manner of growth the Arabian coffee was most curious, for in one part of the bed in which it was planted, the plants had grown to a height of 10 or 12 inches, bearing two or three pairs of primaries, and all of a most healthy colour, while immediately alongside of this group, and in the same bed, were some small sickly little things that could hardly be thought to be one and the same with those beside them. Liberian coffee is also very irregular as regards growth, some trees having the first pair of primaries at 13 inches from the ground, while others ran up to 6 feet without a single branch! Cocoa has been tried, but it would be premature for me to pass an opinion on this subject, while the cultivation of this product is yet in its infancy. Ceará rubber begins to flower at 18 inches in height and appears not to thrive particularly well, if regularity, or I should say, irregularity, is a criterion of success.—Local "Times."

AUSTRALASIAN TREES IN THE ISLAND OF ARRAN.

(EDINBURGH BOTANICAL SOCIETY.—Nov. 3.)

The Rev. D. Sandsborough, Kilmarnock, gave a report on Australian and New Zealand trees and plants grown on the east coast of Arran. He said:—

The island of Arran enjoys a climate in which the severity of winter is as little felt as in any part of Britain. The east coast is specially mild, as here cold frosty winds are tempered by crossing the sea, while their force is destroyed by the high mountains of the Goatfell range rising immediately from the coast to a height of 2,866 feet, which so lift up the wind, that trees along the coast instead of being scourged, actually in full luxuriance overhang the sea at high tide. He had therefore confined the experiments he had been kindly permitted to make, to this side of the island. The measurements were taken in the beginning of August, and unless otherwise mentioned, are made 5 feet from the ground.

Gum Trees.—The first place is due to the Gums, as these are the loftiest trees in the world. Fortunately my list includes two of the most notable species—the Blue Gum, growing to the height of 330 feet, and famous for its sanatory properties; and the Almond-leaved Gum, which grows in Australia to the height of 430 feet.

Eucalyptus globulus (Blue Gum), at Lamlash.—Girth, 1 foot 7½ inches; height, about 30 feet. Another at Strabane, Brodick, was planted this spring.

Eucalyptus amygdalina, Corrie (Almond-leaved Gum), 25 feet high, 11 inches in girth.

Eucalyptus coriacea (White Gum), Lamlash.—The seed of this Gum was received in the spring of 1879. The tree is now 14 feet 6½ inches in height, with a girth of 1½ inches.

Eucalyptus Gunnii (Mountain White Gum), Lamlash, 3 feet 10 inches in height.

Eucalyptus alpina (Alpine Gum), Corrie, 3 feet in height.

With the exception of the blue and the alpine these species are also growing at the Rev. Dr. Story's, Roseneath; Mr. Scoulars, Tighnabruaich; and at Balinakill, Kintyre. Their hardihood will thus be further tested. In Arran not a leaf of the White Gum (E. coriacea) was even browned in the severe winter of 1879-80. This year at the Forestry Exhibition I saw branches of these and other Gums from Antibes, in the south-west coast of France. They were not a whit more luxuriant than similar branches in Arran, though the rate of growth at Antibes is three or four times greater.

Cabbage Palms.—The Dracænæ (Cordylines) are favourite plants in Australia, avenues being formed of them as at Ballarat Botanic Gardens. They grow in Arran in the utmost luxuriance, and have never been even browned by frost.

Cordyline indivisa, 12 feet 10 inches high (including leaves), 1 foot 5 inches girth 18 inches from the ground; leaves 3 feet 10 inches in length, 2 inches in breadth.

Cordyline Veitchii, 9 feet 11 inches high, 1 foot 4 inches girth at 12 inches from the ground; leaves 2 feet 11 inches in length by 1¾ inch broad.

Cordyline australis, 9 feet 7 inches high, 11 inches girth at 12 inches from the groun l; leaves 3 feet 7 inches long and 1¼ inch broad.

As these Cordylines are in perfect health and growing rapidly, it may be expected that they will bloom ere long. The specimen of C. indivisa was sown in 1872; the others were given him at a later date.

Tree Ferns.—So far as he was aware the Island of Arran is the only place in Britain where Tree Ferns altogether unprotected grow luxuriantly in the open air. Three species have been tried. Cyathea dealbata stood a winter, but was stolen the following summer. The two growing at present at Dicksonia antarctica, 1 foot 11 inches high, girth 2 feet 3 inches; has a crown of sixteen fronds, each about 5½ feet in length by 1 foot 8 inches in breadth. Dicksonia squarrosa, 7 inches high, 10 inches in girth, fronds 2 feet 8 inches in length by 1 foot 3 inches in breadth. Dicksonia antarctica was planted in 1867, when it was very small—about the size of a plant of Cystopteris fragilis. It was ten years before its stem began to grow in height, having in this time acquired its full girth. Dicksonia squarrosa was planted in 1877, and had even then a stem of about 4 inches in height. It is in a colder situation than D. antarctica, and was accidentally much injured a summer ago.

Todea superba and Todea hymenophylloides (not Tree Ferns) both grow well.

Beefwoods: Casuarina equisetifolia (He-Oak), 10 feet 10½ inches in height, was planted in 1882, when it was 8½ feet high. He hoped by another year to try E. quadrivalvis (She-Oak) and E. suberosa (Cork Oak), of both of which he had specimens.

Pittosporums: Pittosporum tenuifolium, planted this year in Brodick Castle High Garden.

Brambles: Rubus australis, planted this year in the Brodick Castle High Garden on a north wall, where it is growing admirably, and has a more tropical appearance than any plant in the garden, its leaves being even finer than those of Aralia Veitchii and much more curious, as they are studded over with little white prickles. They would form a beautiful fringe to a bouquet. If abundant in Australia its innumerable prickles must render it a perfect torment in the bush, for they are sharp and turned back and will catch and hold and tear.

Wattles: Acacia melanoxylon (the Black-wood of Australia). This tree, so valuable as an ornamental timber in Australia, had not a leaf browned by the severe winters four or five years ago. It grew most luxuriantly, which proved its destruction, as it was blown over by the storms of last winter. A. pycnantha (Golden or Broad-leaf Wattle) a young plant in Capt. Bunn's garden, Lamlash, is uninjured. A. decurrens (Black or Feather-leaf Wattle), 5 feet in height, in Capt. Bunn's garden, Lamlash. This is a most beautiful plant.

The Bottle Tree (Brachychiton diversifolium).—This curious plant receives its name from its stem at the base swelling into the shape of a bottle. He had the promise of one of these Australian Bottles for Arran.

The Grass Tree (Xanthorrhæa arborea).—This very remarkable plant (see Balfour's *Class-book of Botany*, pp. 92 and 930) is very rare in this country, though well-known in the plains of Australia. Through the kindness of a friend

its leaves are now waving in front of his house, enjoying the great heat of our present weather (August 11). Soon he hoped to see them waving in a favourable situation in Arran. He might mention that he saw yesterday in the possession of James Wilson, Esq., Kilmarnock, a walking-stick of Grass-tree wood. It had been shown at the Dunedin Industrial Exhibition.

Miscellaneous Plants, not Australian.—Camellia (blooms freely), Myrtle (blooms abundantly), Budleia globosa (in bloom, very beautiful); Desfontainea spinosa, 7 feet 6 inches high, and covered with flowers; Photinia serrulata, Elæagnus reflexa variegata, Euonymus latifolius aureus, 4 feet 9 inches high; Coccoloba vespertilionis, Platanus orientalis, 3 feet 8 inches in girth; Schizostylis coccinea, blooms most abundantly every year; Cunninghamia sinensis (Chinese broad-l aved Fir), planted in 1858 by the late Mr. Townley. —*Gardeners' Chronicle.*

PRUNING FRUIT TREES.

The papers noted in the two previous weeks' numbers of the *Gardeners' Chronicle* have been chiefly expositions of the reasons why such and such operations are performed on our fruit trees, but as yet the novice at his work would not be quite sure as to the methods to be adopted in carrying them out in practice. In view of this dilemma we will speak now of this, the practical part, for although a man may be acquainted with the science of his subject, if he cannot whet his knife well, and know when and where to use it, the filling of his fruit-room, and the furnishing the table and the kitchen, will be generally a matter of uncertainty, or he may in the absence of knowledge elect to let his fruit trees get into the distressing state which a correspondent tells us the Devon orchards are exhibiting.

Having an object in pruning our trees, we will say now what that is; it is to fit the tree to the wall, if it be a tender fruit, and if a hardy one, to the espalier, or to form it into a standard or a pyramid or any modification of these. Then pruning and training must go together, for we can hardly speak of the one and be silent about the other. We will take for illustration a tender subject, the Peach, which refuses in this country to ripen either its wood or its fruit away from the forcing aid of a sunny wall. The plant arrives from the nursery, we will assume, as a maiden, that is, a little tree one year old; from the bud it is well ripened, and should not be very gross, or else it will be found that the large wounds necessarily made on it heal only after the lapse of two seasons, leaving a piece of dead snag under the healthy bark, which often developes into an unhealthy wound. The tree having been planted in the early autumn should be pruned after the hard frosts of February are past—not earlier, else it will be so long ere the sap rises and cicatrising of the cut begins; and owing to that the shoot may die further back to the loss of the bud; and if pruning be delayed till growth has begun there is so much sap lost, besides, the sap having acquired certain directions at the outset, is diverted with difficulty later. The best form for the Peach being the fan, or some slight modification of it, the young tree will need the foundation of the main branches formed at first, and this is best done by cutting it back to 2 inches in length, or even less; from this stump, and chiefly from the dormant and almost indistinguishable buds lying buried in the bark, these main shoots will take their rise. After cutting back, the tree should be only lightly attached to the wall, as the newly-moved soil will settle yet more, carrying the roots with it. When growth commences the young growths are most misplaced—that is, those directly in front and those springing out from the back, none of which could be made to do duty as main branches without forming ugly, and, so far as the flow of sap is concerned, injurious bends. Then the shoots may be left for a week or so longer, when the final choice must be made, those being retained that are best placed, say two on either side or only one. The nursery trade usually adopt the practice of keeping three, one central and two side shoots, but stronger shoots can do more than this. During growth there may be some regulation of these shoots necessary, the tree may grow weaker on one side than the other. In that case it will be as well to unloose the weak side from the wall, or depress the strong side shoots for a few weeks until balance is restored, at the same time pruning off a few of the leaves on that side. The next winter having arrived, the operator must still prune for wood, *i.e.*, the shoots made the previous summer must be cut to about 9 inches in length, afterwards making selection of the best placed ones as before but leaving three or four on each of the side shoots, and as many as it may be possible to get equally distributed on the middle one, which should have been cut back to 2 or 3 inches as before. This is done for two reasons; in the first place, because the shoots springing from it, being nearer the erect line will benefit more by the flow of sap than those, and being cut into the dormant buds, will be later in developing shoots, thus giving the side shoots a few weeks' start, which is of great advantage to them, as the sap will have acquired a current in their direction, that will always afterwards be retained. The other reason for cutting the middle shoot so hard back is to do away with an upright stem, always an objectionable feature in stone fruit trees, as when by any chance the shoots should be lost from this, they are scarcely ever fully replaced by new growths.

The regulation and pruning off of all unnecessary laterals, and the raising or depressing of shoots, must be attended to as before, the tree now beginning to assume the intended form. In the following February the main shoots must be again pruned back, but not so hard, and may be left at 15 inches or more in length, and the centre shoots having become numerous, have no need to be kept so much in check, nor yet be so hard cut back to obtain shoots. It will, nevertheless, be essential to control the almost vertical growths by fastening them first of all to the wall, whilst the young wood of the side branches may be allowed freedom from all training for two or three weeks, thereby giving strength to these, but checking the two rash growth of those. If this should not be found a sufficient check to the central growths, some of the leaves may be cut off, or only the half of a leaf taken over the greater part of the shoots; this, with bending the shoots with their points towards the earth, will usually effect the purpose intended —the forcing the sap into the side branches. After equalisation of growth becomes evident, the hitherto loose shoots may be fastened in. The pruning and restriction will now begin to bear fruits, and flower-buds will form themselves on the twigs, which have now become more numerous. In the third year, if the tree has made good progress, a few fruits may be looked for, and the bloom-bearing shoots cut back into ripe wood. The fruiting of the tree at this date must be ascribed more to the treatment it has received in having the weak and crowding shoots cut away, and by reason of its wood by those operations getting fuller exposure to the sun, and by the multiplication of impediments to the free passage of the sap, which a large ramification of the branches causes. These impediments cause the sap to move sluggishly, which in itself leads to the formation of fruit-buds.

Nature acts in the tree as if under our treatment it were in imminent danger of being killed, and therefore endeavours to reproduce its kind by seed (fruit) before that event occurs. The successive treatment of our typical tree follows pretty nearly on the lines laid down in the later years of its formation, using the pruning knife sparingly in early spring, but cutting away misplaced shoots, and those not required during growth, and endeavouring to so treat the remaining wood by keeping it thinly distributed over the tree that it gets the maximum of heat and light. In making cuts, either in winter or summer, great care should be taken to cut always at an obtuse angle across the shoots, and so close to the bud that no snag remains to die back, and to require for its removal a second cutting-over at a later period. Long slanting cuts, even if they end just above a bud, impoverish the top bud, sometimes cause the portion left to wither up, and are always a long time in healing over on account of their area. Shoots that are cut away at their base should never be cut without leaving a trifling stump, which, being small, soon heals; whereas a wound as large as the actual base of a shoot would be a long time in doing so, and would in all probability in stone fruits terminate in obstinate gumming.—*Gardeners' Chronicle.*

DEW.

BY R. PURYEAR, LL.D., PROFESSOR OF CHEMISTRY IN RICHMOND COLLEGE.

Dew has long been a favorite theme alike in the realm of fancy and of science. Poetry has characterized the dew drops, sparkling in the morning sun on grass and flower, as the tears which pitying angels shed upon a sorrowing earth. Science explains how and when and why the glittering spherules are deposited, and, in doing so, robs the subject of its sentimental and poetic interest. Abundant compensation, however, is made in the new features and added charms with which science invests the subject. Nothing is simpler than the formation of dew. Indeed, we make it every day. A pitcher containing ice water soon has its outer surface coated with drops of water, and these little drops of water are really dew drops. What has happened? Only this: the chilled surface of the pitcher has robbed of its heat the aqueous vapor of the surrounding atmosphere, and so has condensed it into water. Dew is formed in nature in precisely the same way, the only difference being in the mode of obtaining chilled surfaces.

Let us see. The atmosphere is always charged, more or less, with aqueous vapor. The earth is always throwing off heat into free space by the process of radiation. During the day, however, the earth receives, as a general statement, more heat from the sun than it loses by radiation. Its temperature therefore rises during the day. At night, however, heat being lost by radiation, and none being received from the sun, the temperature of the earth's surface and of all bodies on the earth's surface sinks. Now the atmosphere brooding over surfaces thus chilled at night by radiation itself becomes chilled; and its aqueous vapor, losing heat, is deposited upon the chilled surfaces as water or dew.

What are some of the leading circumstances that modify the deposit of dew?

(1.) The hygrometric condition of the atmosphere. When the atmosphere is saturated with aqueous vapor, then the slightest reduction of temperature will cause a deposit of dew; and the deposit will be very copious if there be a large reduction of temperature. Hence, as we walk out in the morning now, during the present distressing drought, we find but little dew on the grass. The explanation is obvious. The air is arid, and hence, though all other circumstances favorable to the formation of dew exist, the deposit is small. The material for forming dew—aqueous vapor—is scant, and hence the scanty deposit of dew.

(2.) We notice a remarkable difference in the amounts of dew deposited on different objects. When there is a moderate deposit of dew, some objects, as living vegetation, have quite a good supply, while other objects, as dead matter of every sort, have little or none. When the supply of dew is copious, we find the grass literally drenched with it, while there is largely less on the rocks and fences and dead vegetation. Those objects that need dew have a corresponding power of causing its deposit, while those that do not need it show a corresponding lack of power. In other words, all objects have the inherent power of causing the aqueous deposit in the exact proportion of their wants, so that when the supply of dew is moderate, the whole or nearly the whole of it is deposited upon such objects as need it. Those that do not need the dew receive it only when the deposit is extremely copious, and nature can afford, as it were, to be prodigal in the bestowal of her gifts. Why this wonderful difference in the capacity of different bodies to cause the deposit of dew? A word explains. Different bodies lose heat very unequally by radiation, and of all bodies, that power is greatest in living vegetation. Grass and growing vegetation of every kind, losing heat by radiation much more rapidly than dead matter, suffer of course during the night a much greater reduction of temperature, and hence a correspondingly larger amount of dew is deposited upon them. But for exigent duty, we might stop to moralize on this beautiful and wonderful provision, which gives to every waving leaflet the power of abstracting from the atmosphere the water which it needs.

(3.) Another circumstance which modifies the deposit of dew is the clearness and stillness of the atmosphere. Other things being equal, the deposit will be larger on clear than on cloudy nights. Why? When clouds overhang the earth, they reflect back the heat and so prevent its dispersion in free space. Hence the sultry, stifling character of cloudy nights in hot weather. Heat being thrown back to the earth by the overhanging canopy of clouds, the earth and objects upon the earth are chilled but little, if at all, and hence the deposit of dew is small. Nor can the deposit be abundant unless the air be still. Consider a meadow of green grass rapidly radiating its heat into space during the clear, still night. The grass soon becomes chilled to the dew point and the deposit is made. But if the weather be windy, the air cannot brood over the chilled grass long enough to have its temperature reduced sufficiently for the condensation of the aqueous vapor of the atmosphere. Hence, on windy or cloudy nights, how favorable soever other circumstances may be, the deposit of dew is always small.

When frost, which is frozen dew, is threatened, the farmer, particularly the tobacco grower, is relieved of all his fears if at nightfall either a good breeze springs up or clouds begin to form.

In the above we showed that the deposit of dew is most abundant on those objects that need it most. By another wonderful and beneficent arrangement, the deposit is most abundant when it is most needed. When is dew most needed? We answer in the spring and fall; particularly, in this latitude, in the months of April and May, and September and October. Why? In April and May, seeds are planted that are to fructify in the summer and autumn. They are covered slightly, only a few inches, sometimes barely one or two. They germinate in the warm and humid soil, and soon appear above the surface. But the young rootlets are so near the surface at first that a few dry days would so exhaust the surface soil of moisture that the plants would perish. Before the roots have struck down deeply into the permanently moist soil, and when they must rely therefore upon the first few inches of surface soil for a scant and precarious supply of water, kindly nature, mindful of the situation, every night gives the baby plants a little extra pap in the form of dew.

It is obvious then that during the first days and weeks of plant life, dew is most needed, because at that time the rootlets must get their supply of water from near the surface, which is liable to become dry by only a day or two of hot, windy weather. A supply of water, extraneous to the soil, is needed, and that supply comes every night from the condensation of the aqueous vapor of the atmosphere. That the supply of dew is vastly more abundant in the spring and fall, when it is most needed, than it is in midsummer, when the need is far less imperative, is too familiar and obvious a fact to have escaped the notice even of the least observant.

Now, let us look into the cause of the fact; let us see the operation of these agencies, which give us abundant deposits of dew at those seasons of the year when vegetation most demands it, and diminish the supply when the demand is diminished.

Why should the deposit of dew be so much more abundant in April and May than in July and August? We will recur briefly to the mode of the formation of dew. Objects, to have dew deposited upon them, must become sufficiently chilled at night, by the radiation of heat, to condense the aqueous vapor of the atmosphere. All objects must be reduced in temperature to the dew point. This is much more easily accomplished in May than in August for two obvious reasons. In May the sun is not so hot, nor does it shine so long, as in August. The temperature of the atmosphere and of the earth's surface is not so much elevated in the day in May as in August. To get dew then objects have to sink at night to the dew point from a much lower temperature in May than in August. In the latter month, they must sink from eighty or ninety degrees, in the former, from sixty or seventy degrees, to the dew point. In order therefore to get a copious deposit of dew, plants have less work to do in spring or fall than in summer; but not only so, they have more time to do it in. In May and September, the nights are longer than in July and August, and hence plants have more time to radiate their heat into space. In the spring and fall, plants, in order to get dew, have less work to do and more time for doing it than in summer; and hence the abundant deposits in the spring and fall, and the scant supply in midsummer.

Why, one may ask, is dew less needed in the hot months of summer than in the spring or autumn? For an obvious reason. As the season advances, the roots are striking down deeper and deeper every day. In summer they are six, ten, fourteen or even twenty inches or more below the surface, where it is always comparatively moist. Rain may not fall for weeks, yet they are getting moisture from below all the time; but when plants have just completed germination, and when their roots are near the surface, a drought of a few days would be fatal but for the nightly deposits of dew.

It may be asked again what is the necessity of the heavy dews in the early fall, when the crops are gathered and housed? Precisely the same as in the early spring. In the early fall, the seeds are sown which are to fructify the next year. Wheat and oats, rye, turnips, the grasses, etc., need the autumnal, as the already ripened crops need the vernal, dews.

To another point I will call attention. To get copious deposits of dew, plants must be chilled; but if chilled too much, the dew is frozen into frosts, and vegetable vitality is destroyed. To secure a benefit, a danger is incurred; but in the very process of securing the benefit, the danger is weakened. Vapor is water with so much heat in it—heat in the latent state. When water boils, no matter how much heat we add, we neither make it nor the escaping vapor any hotter. Both have the common temperature of 212 degrees. All the excess of heat we add is simply employed in causing the liquid water to take on the gaseous form of vapor. Now when we condense this vapor, the heat, before latent, is evolved or given out. When aqueous vapor is in the process of condensation into dew, all its latent heat—that heat which made it vapor—is evolved on the surface where the condensation takes place. Consider a fine tobacco field, the broad leaves ripening in the mild September. The leaves lose heat rapidly by radiation, they become chilled, the aqueous vapor is condensed into dew, but in the act its latent heat is evolved, and so warms up the leaves, and thus diminishes the liability to injury from frost. The atmosphere immediately brooding over the leaves is sensibly warmer than the atmosphere elsewhere. If the same amount of water be sprinkled at night-fall upon the leaves, the cold may be sufficient to freeze it; but not sufficient if this water has been condensed from vapor, for the process of condensation throws out, in sensible form, the latent heat of the vapor.

The process of aqueous condensation, or dew formation, postpones the appearance of frost. Plants must become chilled to form dew, but, in the condensation of aqueous vapor, heat is thrown out to prevent frost. This battle goes on for weeks, until at last the increasing length and coldness of the nights get the advantage. The cold is too great to be counterblanced by the heat evolved from aqueous condensation, the dew freezes as it forms, and the plant is killed.

We have shown the necessity of dew in the early fall to the crops that are seeded then, which are to live and grow through the winter and mature in the next summer. But some crops, already ripening, as tobacco, are remarkably benefited by the early autumnal dews. Little rain and copious dews in the early fall make tobacco leaves thick, heavy and oily. Alike, its weight is increased and its quality improved by comparatively dry weather and heavy dews. Dew then, to some extent, has a double function, furnishing to all plants, in the earliest stage of their growth, small but frequent supplies of water, when the supply from the soil is liable to be scant, and enabling others, notably tobacco, to attain, while approaching maturity, their highest perfection.—*American Farmer.*

VANILLA BEANS.—These are the fruits of an orchid.—Vanilla planifolia, a native of Mexico, but which extends north to the borders of the United States. Though the writer has seen it under culture for nearly half a century, he does not remember ever seeing a seed vessel produced under these circumstances. Most orchids only seed when under the attentions of insects, and perhaps this is why it yields its "beans" or seed vessels so freely in a wild state. The island of Tahite sends out about 2,000 or 3,000 pounds annually.—*Gardeners' Monthly.*

CASSIA OCCIDENTALIS.—The seed of this plant, which is occasionally found in the Southern States, contain no caffeine, nor any other alkaloid, but some fatty oil which easily becomes disengaged and empyreumatic upon application of heat to the seeds, in a partially closed vessel. The parching or toasting of the seeds causes volatilization of water contained therein; then the oily substance makes its appearance on the walls of the container, accompanied by an odor closely resembling that of parched beans or peas, very remotely, and with some imagination only, simulating that of coffee. Treatment of the parched seeds with dilute alcohol, as also the turbid, brown watery extract, developed the presence of phosphates of lime, potash, and soda.—*Independent Journal.*

THE AMOUNT OF WATER ABSORBED BY TREES.—In the official report of the Geological Survey of Wisconsin is an account of the determinations made by Dr. J. M. Anders of the amount of water pumped from the earth by trees. He finds that the average exhalation from soft thin-leaved plants in clear weather amounts to about 1¼ ounce Troy, per day of twelve hours, for every square foot of surface. Hence a moderate-sized elm raises and throws off 7¾ tons of water per day. In the report the facts are applied to what is going on in America, where certain inland fertile districts are becoming converted into deserts by wholesale clearings; and in other places, such as the plains of Colorado, where only five or six years of irrigation and planting have already produced a measurable increase of rainfall. It is maintained that the deserts of Syria and Africa are the results of cutting down trees, and that original luxuriance may be restored by skilful replanting.—*Timber Trades Gazette.*

PEARL FISHERIES OF PERSIA.—The pearl fisheries appear to be in a languishing condition. Formerly a very large source of revenue, they are at the present day probably not worth to the Government more than 50,000 tomans or £16,000 per annum. The pearl beds are farmed by the chief men of the adjacent towns, and, instead of being distributed in Persia, are for the most part sent to Europe by the steamers plying to the Persian Gulf. The reason for the present condition of the Persian pearl beds is that they have been allowed no rest, but have been constantly worked. In Ceylon, the pearl oysters are allowed a rest for intervals of two years, during which they are allowed to mature. Mr. Benjamin says there is reason to believe, however, that the beds at the island of Karâk, near Bushire, which have not been worked for some time, are now in a condition to repay capital expended there, especially if diving is extended to a depth of fifty to sixty fathoms. As the ordinary depth reached by pearl divers is rather less than this, the Persian Government have recently sent to England for diving dresses of the latest invention, and an experienced diver has been engaged at a high salary. With the assistance of these, it is expected that the pearl fisheries of Persia will regain their former importance.—*Journal of the Society of Arts.*

INJURIOUS INSECTS.—The first injurious insect competition ever held took place at Frome in England recently. Miss E. A. Ormerod, F.M.S., the consulting entomologist to the Royal Agricultural Society of England, offered prizes of £3, £2 and £1 for the best collection of specimens of food plant injured by insects, accompanied by samples of the insects injuring them, by a short written account of the insect attack, and of the methods of remedy or prevention adopted. Only one exhibit turned up, and this was judged by Mr. Henry F. Moore, who awarded it the first prize. It was sent by Mr. Herbert Haley, of Feltham Cottage, Frome, and was a most instructive and picturesque arrangement. The specimens included plum, geranium and red currant leaves attacked by caterpilars, potatoes and spinach by wireworms, turnips by turnip fly, celery by grub, strawberry by chrysalis of caterpillar, potato by Colorado beetle, branches of gooseberry tree stripped by saw-fly, cabbage leaves by butterfly, onion by maggot, filbert tree by various insects, stephanotis by mealy-bug, centipede, daddy longlegs, earwigs, &c. Each insect was shown in a separate bottle, and there was a short account of the insect attack, and of the methods of remedy or prevention adopted. The specimens were also accompanied by colored drawings of the insects, life size or greatly magnified. It is greatly to be regretted that only one entry was received, but the interesting nature of the exhibit will be certain to cause it to be repeated in other places.—*Australasian.*

A FEW PRACTICAL HINTS FOR CEYLON CINCHONA GROWERS.

[Forwarded with the compliments of Messrs. S. Rucker & Co., London.]

Since planters had their attention drawn to the requisite preparation of bark for the London market by Mr. T. C. Owen's work, and others, prices have fallen to a point that makes it a matter of considerable importance as to what bark should be harvested at all, and, if harvested, whether it would not be best to accept whatever price is obtainable locally in preference to shipping at a loss; and again, taking into consideration the flood of low-class barks constantly coming forward, it becomes a question whether more money could not be made out of the bark that is shipped, by following certain suggestions contained herein. A fair proportion is shipped in excellent order, especially the renewed barks, but it is, as a rule, in the commoner parcels that there is scope for a good deal of improvement. If anything I may write should be of assistance to planters in enabling them to secure a better average of prices for their shipments of barks, and help to clear up doubts in their minds as to the most profitable method of placing their bark on the London market, these few pages will not have been written in vain. Many planters have it in their power to increase the value of their parcels considerably, and many have already discovered that it pays as handsomely to thoroughly prepare all cinchona, intended for the home market, as to thoroughly prepare any other product they may grow. In the very infancy of the enterprize, the preparation, through inexperience, was comparatively nil, yet the prices were always satisfactory. Competition was brisk, and the demand for all kinds of Ceylon bark, as soon as its full worth was known, was surprizing. In those days, unfortunately, the supplies were so small that few only benefited by the fine prices. Now, however, owing to the enormous increase of supplies, matters are different, and other countries growing cinchona—such as Java, Bolivia, &c.—may shortly run Ceylon into closer competition, necessitating, therefore, care and vigilance. The progress made has certainly astonished everyone; for not only has Ceylon become the chief cultivated bark producing country in the world, as regards quantity, but she is sending into the London markets parcel after parcel of renewed growths, with analyses scarcely conceived in the days of the best South American calisayas. Just at present the price has fallen a good deal below what we may expect in the future, owing to various causes as unexpected as they are disheartening; but the position of the article is good, and men will do well to learn all they can to make the utmost of the fortunate prize which has fallen into their hands, and which is steadily riding many on to renewed prosperity, especially if, as it seems probable, the yearly average export of the future is not to be maintained. Men must be prepared to face a little more expense on the estate in curing, in order to send home their bark in *first-rate condition* throughout. The curing in Colombo can only effect certain objects, but the assortment, the cleanliness, the most profitable method of taking the crop, &c., must all be decided and seen to on the estate itself. Again and again planters have suffered disappointment, not only from a falling market, but from the poorness of the analysis, and the prices consequent thereon. Many an otherwise valuable parcel of bark has been spoilt by mixtures of twigs, of stones, of coir, and of lumps of wood, &c., all of which must naturally lower the analysis. Cleaning and sorting should nearly all be done on the estate at the time of harvesting. Frequently have I been asked, why such-and-such a lot sold so badly, and judging from the appearance, and in most cases it is possible to value approximately from the appearance, my only answer could be, it sold for what it seemed to be worth. Common grades of bark there must be; but even those I am convinced, from practical experience, if it pays to ship, it pays to make the most of by carefully eliminating all extraneous matter and twigs, which, if worth harvesting at all, should be sold locally, for they cannot pay their cost in freight and charges at present value, and, if mixed in with fair bark, do far more harm than good. Where the locality is suitable, and the mortality not unusually severe, and where proper regard is paid to harvesting and curing throughout, it is possible the cultivation of Cinchona, combined with other products, is, and will be, more lucrative than any other in Ceylon; and for this reason men would do well to plant a certain number of trees every year.

QUILLS.—There still seems to be much uncertainty regarding the kind of quills required in the trade, and many have suffered both disappointment and loss by sending home renewed quills, young papery quills, quills from varieties undesirable for the purpose, such as calisaya, pubescens and hybrid, which would only be bought on analysis. All these should have been shipped in bales as stem chips. My impression is that it only pays to harvest as quills, original succirubra, from four-and-a-half to five years old at the earliest, and then only from trees of stout growth. The quills should be 2 ft. in length, well assorted, and quite even. They should be packed in cases, and care should be taken that no small pieces are inserted to fill up crevices. Good officinalis quills have brought high prices, but I think other ways of harvesting officinalis are more profitable. The tops of the trees, where the bark is naturally weak, scarcely pays to harvest as quills, and should, therefore, be broken up into stem chips. Stout, clean, even, well-assorted 2 ft. natural succirubra quills always command a good price, but they must be packed carefully to avoid getting broken. The more silvery the better, and the lichen should in no case be removed, as it apparently gives them a traditional value in the eyes of druggists On no account should renewed barks be shipped as quills.

CALISAYA.—With one or two exceptions (notably Stellenburg and Penmynydd) this bark is by far the most unprofitable kind grown in Ceylon, and could with advantage be replaced by something else. When harvested, it certainly should not be quilled.

ORIGINAL SHAVINGS, if not taken from too young trees, seem to realize paying rates. Care should be taken to keep them clean and free from twigs, and parcels should contain not less than 500 lb.

RENEWED SHAVINGS.—I have noticed parcels with this designation that have contained as much *natural* as *renewed* bark in them, in addition to twigs and extraneous matter; the analysis naturally corresponding with the sample. On the whole, however, this class of bark is better prepared than any other that comes on the market, with the exception of renewed chips.

ORIGINAL CHIPS.—In these parcels I would suggest more assortment, and the winnowing out of inferior stuff, which lowers the analysis and does not really pay to ship. A large shipment of chips would frequently stand a good deal of picking over before leaving the estate.

RENEWED CHIPS.—In most cases the preparation of these, both of officinalis and succirubra, has been very good. They have evidently been more generally adopted than shavings in the past year, owing to coppicing I conclude, and prices on the whole, for this class of bark, have been satisfactory.

ROOT.—The price for root continually varies. When supplies are heavy, root is the first to fall; if supplies are light, root immediately rises in value. Fine bright succirubra root sells readily, and prices for this description are well maintained. The process of cleaning suggested in Mr. T. C. Owen's work is not always carried out, *viz.*, "to wash the root in a running stream before taking the bark off," or we should not hear of manufacturers giving up buying root on account of the dirt. It must pay to thoroughly clean root bark, and that is a point worthy of attention in view of the falling off in supplies from Ceylon.

BRANCH BARK AND MIXINGS.—Both officinals and succirubra mixings, if of fair quality and in good order, are most profitable shipments, yet it is in these parcels especially that the valueless twigs and extraneous matter are so often found. What I describe as "mixings" generally contain some shavings, both renewed and original, some chips, original mostly, and good stout branch, &c.; eliminate from these the twigs and the rubbish, and you have a very useful parcel. The extra expense and attention to these lots would give a nett result considerably higher than that obtained for most of these shipments at present, and would, I think, well repay both.

TWIGS.—At present rates it does not pay to ship succirubra twigs, and growers should only harvest them for the local market. Officinalis and ledgeriana twigs could be shipped if it is known they contain a good analysis, but it must be borne in mind that a 1 per cent analysis of twigs is not equal to much more than a ½ per cent analysis for

other barks, but let them on no account be mixed in with good bark.

LEDGERIANA.—Very little of this variety has, at present, come on the market. Original shavings, so far, have sold better than renewed, but, perhaps, after the first renewal the analysis may improve, as has been the case with succirubra—the fourth and fifth renewal showing the best results of all.

QUANTITY.—No assortment should contain a less quantity than 500 lb. otherwise it runs a chance of not being tested by the buyers. Quills, and very fine lots of renewed barks are an exception to this rule.

MARKETS.—I think it will be found that a *careful preparation* of Cinchona bark will decidedly command the special notice of buyers towards those marks where such attention is continuously bestowed.

Of course, added to all this, an important element exists in the judicious management of sales in the London market, and this becomes a distinctive feature of the London merchant and the broker, who naturally should be fully competent to form a fair opinion as to the prospects of the market, and the best and most suitable time for realization, so as to secure the highest obtainable prices, as they have not only to study the supplies from Ceylon alone, but from all parts whence Cinchona is imported; and also to be guided by the statistical position of the article, and the present and probable future demand. But prices must necessarily vary, according to fluctuations of market, and it is no criterion to suppose that because the bark from one estate realizes a certain price, bark from an adjoining estate, though of apparently corresponding soil and aspect, should, therefore, realize a similar price, as the alkaloid results and general quality and preparation may, and do vary even from estates approximating each other. Then again, as to the time which elapses between one sale and another, many circumstances frequently intervene to alter prices very materially.

Nor can the price per unit be so defined as to be applied in exact proportions to all analyses:—for instance, bark yielding 4 to 5 per cent. of sulphate of quinine, might, from its superior results, sell at 7d. per unit; while another bark, only yielding 1 to 1½ per cent, might not bring more than 5d. per unit, if so much.

This is an important fact to be borne in mind, as it has been verified by experience.

Sometimes, too, the other alkaloids, such as Cinchonidine and Cinchonine, have a value, whilst at other times they are ignored, as is the case at present; *just now* officinalis barks sell more readily than succirubra, owing to their possessing but few alkaloids besides quinine, and, in consequence, are more easy to work.

A good deal of the above is familiar to most planters, but it cannot be familiar to all, or the mistakes that are made would not be continued. Personal observation, and the complaints of planters themselves, have shown me that the only real improvement in the preparation of the bark must be made at the time of harvesting, and then it is a matter of outlay and care more than anything else.

JOHN HAMILTON.

12, Great Tower Street, E. C., London.

COFFEE PROSPECTS IN BRAZIL.

The extreme importance that the coffee crops, of the provinces of Rio de Janeiro and Sao Paulo, are to the financial position of the empire, renders a reasonably correct estimate of their probable outturn a matter of the greatest moment. These estimates have been, whether purposely or not, we do not consider ourselves called upon to discuss, so often erroneous, that incredulity, generally, is felt when the *short crop* cry is heard, and the fact of the matter seems to be, that until very recently but little trouble was taken and less opportunity afforded to estimate with any degree of exactness the probable yield of the two principal coffee-producing provinces. The increased extension of railways, the development of the press and the approximation of producing and consuming markets through steamers and telegraphs have partly corrected the hitherto vague crop estimates and we are assured that each year these become nearer and nearer to the reasonable correctness desirable in so important a matter. Last year (1883-84) the estimates as to the outturn were proved correct by the shipments, and it is therefore, at least, a fair supposition that the estimate of this crop will be approximately correct; 3,500,000 bags has been and still is generally considered the crop of Rio and about 2,000,000 that of S. Paulo. The crops are being marketted more rapidly than was ever before possible and the financial position of the planters has obliged most of them to hurry forward their coffees, so the impression gains ground, that, as happens with the cereal and cotton crops in the United States, very large entries in the first half of the crop year will be followed by moderate, or small, receipts of coffee for the latter half. If the receipts for November and December of this year do not exceed those of last, we will have received for the first half of the present crop year about 2,450,000 bags; nearly 400,000 bags more than last year and the reserves of Rio coffees would be about 1,000,000 bags. As to the 1885-86 crop it is much too early to speculate upon the production. So far the estimates for the Rio crop give an average yield, but it is supposed that the area of production shows an annual increase; from Sao Paulo the printed reports are not favorable. The question then remains as to how with so small a possible supply of our only *bullion*, the exchanges are to rule during the latter part of the crop year? The position of the treasury renders some financial operation unavoidable and the three solutions of the question; a foreign loan, a domestic loan, or an emission of paper money must be considered. A foreign loan, we believe, could be negotiated, but at a severe charge upon the country and the ever increasing demands upon the exchange market would be further augmented. An emission of paper money would be simply suicidal, but we think that an internal loan could be made, if some provision were inserted that the capital invested should not become utterly withdrawn from trade; and this is only possible if a national bank law be passed through which the new loan would become the basis for an issue of paper money based upon some tangible security. Every day's hesitation is seriously affecting the business interests of the whole empire and the erratic fluctuations in the exchange market are becoming seriously alarming, so that the Government is bound to offer some solution and we trust they will accept our suggestion as to this.—*Rio News*, Nov. 24th.

TEA CULTIVATION IN MAURITIUS.

The cultivation of tea in the Island is the all absorbing topic at the present time, and from what we hear it will become a staple product ere long. The Hon. L. Raoul has moved in Council on the subject and we have every confidence in our "go ahead" Governor to afford all necessary help His Excellency we learn has had a sample of rough manufacture sent to him by Mr. Davies, tested and tasted, and from what was said at the Exhibition we would infer that His Excellency was pleased with the result. The Hon. Sir V. NAZ, K.C.M.G. who who is always foremost for the good of the Island, offered a grand silver medal at the Exhibition for the best sample of tea grown and prepared in the Colony, which was awarded to Mr. D. Picton Davies who for the past two years has been testing the culture and manufacture of tea at Curepipe and calculating the probable results, and he declares it will prove a "product of importance and profit to the Island." We hear Mr. Davies has raised a number of tea seedlings of high culture from Japan seed, and that he placed some of them at the Exhibition, which were admired by many, but taken no notice of by the Committee.—(*M. R. & C. G.*, 13th Dec.)

GUTTAPERCHA CEMENT.—An excellent cement, which may be used instead of putty in glazing windows, or for cementing metal glass, porcelain, ivory, &c., is made by melting together in an iron pan two parts of common pitch and one of Guttapercha, stirring them together until thoroughly incorporated, and then pouring the liquid into cold water. When cold it is black, solid, and elastic, and it softens with heat, and at 100 Fahr. is a thin fluid.—*Indiarubber and Guttapercha Journal.*

Correspondence.

To the Editor of the "Ceylon Observer."

GRUBS AND COCKCHAFERS.

DEAR SIR,—Considering the countless millions of grubs in our coffee soil, I have often marvelled at the scarcity of cockchafers on the wing. In fact, I am not sure that I ever saw one? This evening, however, a large flowering tree at the end of my verandah was alive with large buzzing insects, flying from flower to flower with amazing rapidity, coming, however, to absolute rest, while still on the wing, *instantaneously*, while they inserted their long proboscis into the depths of the flower-cups. Are these the Ceylon cockchafer? or what? After all, "grub" is the greatest of all the coffee pests, bringing Government! With the grub at one end devouring their roots, and the Government at the other devouring the proceeds, heaven help the

PLANTER.

[There can be little doubt the insects our correspondent saw were cockchafers, which will, in due time, deposit grubs in the soil. In Europe these grubs seem to require three years to develope into the winged state, but here it is supposed that half the period may suffice. Anyhow, grub is certainly a great evil, and we fear there can be no question it has been aggravated by the non-burning of the patanas.—ED.]

NEW AND OLD LAND FOR TEA.

9th Jan. 1885.

DEAR SIR,—Your correspondent with the long signature, in your issue of yesterday, treats us to a long letter which is very difficult to read; so much so, that it would be well if he would condense it into half the space with a little table of data, as we should then be better able to get at his meaning. The question is an interesting one, but has more importance for new men than for existing proprietors. Those of us who have old estates upcountry where coffee is dying out and cinchona is sticking, but with fair soil, and buildings, roads, drains and open-land—which together represent a capital expenditure of many thousand pounds—are not going to abandon our estates in the face of yields like those of Mariawatte, Imbulpittia, &c., whose history everybody knows. I cannot speak from personal experience, but, proverbially, the soil throughout the "lowcountry" is poor. On many of the old estates "upcountry" the soil—where it has been preserved by a good system of drainage—is as good as ever it was; but we must take the good and bad together, for tea as we have always done for coffee. I believe *all* the present coffee estates are destined to become paying tea-gardens, but whether by the means of their present or future owners, time alone will show. Those present proprietors who *have* the means, with coffee and cinchona to help, will leave beginners on new land in the lowcountry far behind in the race in a fair comparison of expenditure.

When land has ceased to be cultivated, it immediately clothes itself with verdure in the shape of lantana, or what we call "weeds," when we don't want them or grass or forest. So long as this is left undisturbed the soil is thereby protected and enriched and loses nothing of the "food of plant life." The soil of an abandoned estate, therefore, is better after a long rest than it was on the day it became neglected. Constant cropping of heavy "weeds," or any other growth, impoverishes the soil. But in recent years the crops of coffee have been so small, that the fertility of coffee-land has been but little affected by them, which, if not much, is an item worth remembering.

One thing, however, is becoming apparent; tea upcountry, does not yield its big crops of 500 to 700 lb. per acre until it is seven to eight years old. *Vide* the published accounts of Abbotsford and what is known of other places. This is a lesson for us who come later in the enterprize. We must not sit and wait and depend upon "next year," but *make* the tea grow faster than our predecessors thought it necessary to do by forking the land up *earlier* than they did and not allowing the plant to get sluggish and sleepy as the late Mr. Cameron described it. I quite believe, that, with our accumulated experience, the young tea of today will do better in its fourth and fifth year than the young tea of seven and eight years ago did. Then again, tea is such a "jungle plant," as we read recently in the letters "From the Hills" Once fairly planted (good plants in good weather), it will hold its own against almost anything, coming of course, slower to maturity; always making root, however, so that when once absorbed into the area of cultivation (after years of neglect) it would immediately respond to your attention, put on a respectable appearance after pruning and pay at once. For impecunious proprietors, with a larger acreage than the proceeds of coffee will maintain under cultivation; this is a point of very great importance, and one well worthy the serious consideration of mortgagees (in whose ranks I have myself been, and am now a working-proprietor against my will). Suppose a man has 300 acres under cultivation, and can only afford to keep up 100 in good cultivation, clean and all that, from the proceeds of the whole. If he has this 100 acres planted up with tea amongst his coffee and elsewhere, and would manage to plant up with tea, the remaining 100 or 200 acres, well, then, so long as the estate was kept as a going concern with 100 acres well cultivated, the mortgagees' security would be fast improving, even were the remaining 200 acres seemingly abandoned; for, bearing in mind what has been said above, that the abandoned soil improves during its rest while the tea is establishing *itself*, at the end of four or five years, the whole estate, at a small cost, would become a paying tea estate of 300 acres.

I have just uncovered a small patch of land planted with seedlings four months ago, from thick weeds and *grass* 2 ft. deep, being four months' growth. Not a plant is missing, and they are healthy and well grown, and, compared to the insect-eaten things planted with them at the same time, but always kept clean, they are as kings to beggars. I am afraid, though, their turn has *now* come for attack by the universal enemy of very small tea-plants.

OLD HAND.

TEA MACHINERY AND MANURING.

Ambagamuwa, 12th Jan. 1885.

DEAR SIR,—"The interests of the planter and the machinist are identical," and the latter is very fond of mouthing this fine sentence. But the planter often finds a discrepancy somewhere in the logic of it, when he is asked to pay about twice as much as the concern is worth for a machine, owing to the intrinsic value of the invention! When we are many, and the inventors count by units, then there is the danger of monopoly always present. Now, there is a very popular "Jackson" and a "Sirocco" which will take a lot of beating. They can make their own terms with us. But when I find a Barry and a Kinmond, an Evaporator and a Thompson's "challenge," a Kerr and a Walker's miniature in the lists for competition, then I begin to feel that our interests are really beginning to be identical; somewhat better balanced; one breathes more freely. It suits us therefore to encourage all comers in the field of inventions for tea machinery. Come one, come all. Merit will find its level. Thompson of the "challenge" (somewhat de-

fisant!) roller is back in Ceylon, I hear. His roller seems to be doing a fairly good work. It has certain merits. But there is room for improvement in the twist: a tighter twist is wanted. There is no doubt the tips are preserved by this roller. But I will not enter into a criticism here yet. He is substituting studs for battens, and may improve matters. "Mariawatte" "Blackstone" and "Galbodde" may be able to testify to its merits shortly. I confess, however, I like the look of the "Challenge" in a factory, like a bass drum. There is no energy or force wasted in its motion, rotary, and as easy as greased wheels can well be. But then its twist; "aye there 's the *rub*" (falling far short of the rubbing done by the cooly at present!) which discourages us

"And makes us rather bear the ills we have
Than fly to others that we know not of."

Mr. Thempson had better look to his laurels—his "rub." Then we have the little "Jackson" by Walker. I have it on high authority that it is even better, if possible, in its work than the "Universal." More easy in motion, and of reasonable capacity for small gardens.

"Kerr" flourishes, but little "Jackson" is pressing hard. Kinmond—we do not hear very much of this machine. Why what 's wrong about it? There should be free discussion and register of results, not mere puffing advertisements. I am sure we should write more frequently on machinery, so as to keep our brother-planters informed, for the common weal of Ceylon. Our interests are identical! The planter's and the machinist's, likewise, quite identical!

We have had a smart shower here on the 10th. The first for the year, worth mentioning. But the mercury is rising: hence the dissertation on machinery.

Those were encouraging returns from Abbotsford. *Manure and fork:* if manure is not available, *fork*, should be a standing order. With tea manure acts like a charm. I ascribed my prices last year partly to manuring, and I know of estates with whose leaf even experts will fail to make a high class tea. It is notorious. AGRICOLA.

["Agricola" is just the man to help his brother planters to decide on the questions he raises.—ED.]

NUWARA ELIYA, 16th Jan.—This picturesque spot is looking its very best, and I am glad to hear that so many houses are already taken for the race week. Although it may flavour of painting the lily, I venture to think that judicious planting of ornamental trees (carefully screened from wind till robust) round the lake would add to the beauty of the place. Even bamboos, giant and various, might be tried; too high, perhaps you say, anyhow it would be worth a trial. I have grown and flowered so many things at a high elevation, which I had been told "on authority" would not succeed that I would not despair of success. Nobody should omit a visit to Hakgala. It is simply marvellous the transformation scene which Mr. Nock is gradually effecting even with the miserable pittance doled out to him for expenditure. The new rose garden is a bold and effective design: judging by the strength of the plants, the judicious selection of varieties, and the *composition* laid "fathoms deep" throughout the beds, there ought soon to be a sight to gladden the eyes of every lover of the Queen of Flowers. "Ladies' fingers" are by many esteemed as a vegetable, but in the Hakgala *ferniery* they may easily become an unmitigated nuisance. *Verb. sap.*

ONE OF JACKSON'S TEA-ROLLERS was exhibited at their works today Jany. 16th) by Messrs. John Walker & Co. It is said to be capable of rolling 1,000 lb. of green leaf a day, driven by four coolies. It occupies a space of about eight feet square, strong and substantial looking, and so constructed that it may be driven by machinery. The cost of one of these rollers is about R500, and they are rapidly getting into use.

OLD FRIENDS.—An old Colonist and proprietary planter, Mr. Charles Hadden (whose pioneering days in Ambagamuwa we referred to in one of our New Year stories), has just returned to Ceylon on a visit, which we now trust will become an annual one, in order to escape the winter and early spring in England. Mr. Hadden is full of faith in tea—a leaf instead of a seed crop in Ceylon and a plant with a root capable of penetrating any soil. He looks for a great future to the tea-planting industry of Ceylon.

ROSEWOOD trees are found in South America and in the East Indies and neighbouring islands. There are a half dozen kinds. The name is not taken from the color of the wood, as is generally supposed, but by reason of a rose-like fragrance which it possesses when first cut. Some of the trees grow so large that planks four feet broad and ten feet in length can be cut from them. These broad planks are principally used to make tops for pianofortes. The rosewood tree is remarkable for its beauty. Such is its value in manufactures as an ornamental wood that some of the forests where it once grew abundantly have now scarcely a single specimen. New plantations have been set out, so that the supply will not be exhausted.—*American Grocer.*

CINCHONA BARK PREPARATION.—We call attention to the paper republished in another column from the pen of Mr. John Hamilton of Messrs. S. Rucker & Co., to whom Cinchona planters have been so often indebted for timely and useful information. The debt of obligation is specially increased by the present instalment of hints in which Mr. Hamilton evidently sums up the result of close observation for a number of years of the bark sales and of the several Ceylon parcels offered with resulting prices. The hints as to the preparation of different parcels and of the different species on the estates are so thoroughly practical, that most planters will keep them at hand as a guide to future operations. Notwithstanding all past failures, the aid which cinchona is giving and will yet give to many of our planters, is too considerable not to lead us to welcome all additions to the stock of practical information requisite to successful preparation.

A PRACTICAL EXPERIENCE OF KINMOND'S DRYER.—The following letter has been addressed to our morning contemporary:—Sir, with reference to the relative merits of "Sirocco" versus Kinmond's dryers, which are being discussed in your columns, having had experience of the latter for over a space of twelve months, I regret I am unable to substantiate Mr. Kinmond's statement that his No. 2 dryer can turn out two maunds of pucca tea per hour. My dryer which is a No. 2 is worked by waterpower, and with the fan running at from 500 to 700 revolutions per minute (the speed advised by the patentee), I cannot get more than 110 lb. of made tea per hour, with the thermometer ranging from 280 to 300 degrees, at which latter heat and speed the tea is blistered. I find that a superior tea is made by a heat of 180 to 200 degrees with the fan running at a much less speed than that stated, and the result is an average outturn of about one maund per hour. There are a few other No. 2 dryers at work in the island, and it would be satisfactory if those who have them would state if they can turn out 2 maunds of really good tea per hour, allowing 4 men to handle the trays, and 2 to feed them, exclusive of stoker. The best dryer will come to the front, be it either Sirocco, Gibbs and Barry, Jackson's or Kinmond's, in the same way as Jackson's roller has established ti claim to superiority over all others.—DAVID FAIRWEATHER.—Nawalapitiya, 10th January 1885.

NOTE ON "CHINA BICOLORATA" OR "TECAMEZ BARK," WITH SUGGESTIONS AS TO ITS PROBABLE BOTANICAL ORIGIN, AS INDICATED BY ITS BOTANICAL, CHEMICAL AND MICROSCOPICAL CHARACTERISTICS.

BY JOHN HODGKIN, F.I.C., F.C.S.,

Mem. Soc. Chem. Industry, Medallist in Chemistry, University College, London.

An opportunity has lately been afforded me of investigating this most interesting bark, of which after the lapse of many years a small consignment has recently appeared. But before giving the results of my examination, it will be interesting to recapitulate and epitomize the information that has already been published in various journals and handbooks since its discovery.

In the first place then, this bark comes from Tecamez or Atacamez, which lies west of Ibarra on the western declivity of the Cotocacha, in Ecuador.* Here it was discovered in 1793 by Dr. D. Brown, a ship's surgeon, and a description of it with an illustrative plate was duly published in Lambert's 'Description of the Cinchona Genus,' 1797 (f. 30, tab. ii.). It appears to have been recommended as a useful tonic, in a medical work published in 1824, by Dr. Brera, of Padua. Having thus attracted attention, it was submitted to a careful examination by MM. Pelletier, Pétroz and Vanquelin, and their elaborate report appears in the *Journal de Pharmacie* for Oct. 1825 (pp. 449—462). M. Pelletier states that 100 parts contain 16 parts soluble in alcohol, of which 14·65 is bitter substance" and 1·35 "resin," but they were unable to find any quinine, in which opinion they have been confirmed by Pfaff, v. Santen and others, and still later Dr. Hesse, who states† "that it is altogether destitute of alkaloids." Goebel and Kunze,‡ give an illustration, and a good description of the oark (to which I shall allude later on), and state that Humboldt saw the tree from which the bark is obtained, and was of opinion that its botanical origin was to be sought amongst Cinchonas or Exostemmas, in which opinion M. Weddell§ tentatively coincides, and whilst Guibourt‖ is of opinion that it is a *Stenostomum*, Markham¶ thinks it is probably a *Pinkneya*. Now I propose to attempt to demonstrate by a chain of evidence from different sources, microscopical, botanical and chemical, that there is a greater probability in its being a *Remijia* than any of the above mentioned species. It is best first of all to describe the bark, and to do this I cannot do better than give Goebel and Kunze's description with slight amplifications where necessary. "The 'Pitoya' bark," as they term it, "comes in rolls 4 to 24 inches long, sometimes singly, sometimes many times rolled, and occasionally rolled together. The outer surface is smooth, and extremely finely wrinkled in the direction of the length, sometimes more so, sometimes less so, of a brownish or greyish yellow, with white or grey patches, occasionally spiraliform, encircling the quills, and generally the bark is studded with little warts. The interior surface is smooth, generally of a brownish black colour: occasionally, however, pieces are to be met with of a reddish brown colour. The Pitoya bark is composed of three portions:—(1) The epidermis; (2) the orange-coloured bark; (3) a thin layer of fibre (*Bastlage*). The lower black surface, which is scarcely $\frac{1}{10}$ of a line in thickness, can be removed by a knife, on soaking the bark, and is composed of fibre. The diameters of the quills range from 4 lines to 1½ inch (*Zoll*), and the thickness from ¼ to 1½ lines. One never finds flat pieces, the least so which I have hitherto seen were still feebly bent inwards. The cross fracture is only slightly uneven, the longitudinal fracture is harsh, and often somewhat short splintering. The taste is disagreeable and intensely bitter, strongly inducing saliva. Of odour, I could distinguish nothing. The bark yields a fine cinammon-coloured powder.

Thus says Kunze,* and his description certainly does not leave much to add. I would, however, remark that the sample I had was not so elegantly rolled, and appears to have been removed with less care. Some pieces have a whitish "coat," somewhat loosely attached to the bark, which, as it curls up in drying, loses this epidermis in tranverse stripes, giving a somewhat "zebra" appearance. Some of the larger pieces on the interior present rather a remarkable appearance, longitudinal fissures, at an equal distance having been caused by the drying of the evidently somewhat "fleshy" bark. Such pieces are, however, the exception rather than the rule, as by far the greater portion dries with the smooth dark-coloured interior. The microscopical section of the bark, Dr. A. Vogl† has pointed out, closely resembles that of *Remijia pedunculata*, and he gives drawings of these two sections for comparison, and certainly there is a very striking analogy. Vogl does not offer any suggestions as to the real origin, but simply notes the fact of the resemblance to "cuprea," but, Humboldt, who actually saw the tree, was of opinion that it belonged to the Exostemmas or Cinchonas. But be it borne in mind that at that time, this latter group included the *Remijias*, which were not then so perfectly understood as they are today. In Lambert's illustration of the leaves of the Tecamez bark, the leaves are seen to be of a peculiarly pointed form, closely tallying with the form of the leaves of *Remijia pedunculata*, as given in Karsten.‡ We have thus microscopical and botanical evidence from undoubtedly trustworthy sources which, when noticed in conjunction, and I believe that they have not hitherto been noticed, together, are rather suggestive of the possibility of the Tecamez bark being a *Remijia*. Now I am, through a fortunate concatenation of events, enabled to offer such fresh additional evidence as I think will materially tend to strengthen, if not absolutely confirm, this hypothesis.

In the first place, then, I must mention that among the numerous importations of "cuprea" bark, there has come occasionally a small parcel of a "cuprea," of very different appearance to the ordinary *R. pedunculata*. The bark is of a much more orange red, instead of the dull lake of the ordinary "cuprea bark" of commerce; it comes in very thin, broken quills, or small pieces, and gives almost the appearance of cuprea "shavings." The bark is of fine quality as regards its percentage of quinine. It comes from the State of Tolima (Colombia), and is cut from trees which are very sparsely found, and thus far it does not appear that a large supply will come from that district. It is shipped from Barranquilla, like all bark of the same description. It is evident, from a careful examination of some hundredweights of this bark, that the tree is a small one in comparison with the *R. pedunculata*, and the pieces seem relatively but little larger than the *China bicolorata*, to which with the exception of the colour, it bears a strong family likeness. In fact this bark, the scientific name of which I am unaware of, seems to stand almost midway between *China bicolorata* and *R. pedunculata*. The exterior surface is, it is true, a great deal more longitudinally wrinkled; the interior surface is very similar.

Secondly, then, I must state that my analysis of the *China bicolorata* entirely contradicts the experience of previous observers, for not only does the bark contain 0·75 per cent of alkaloids, but they are cinchona or remijia alkaloids. The bark contains also chinovine and chinic acid, which I obtained in the characteristic lime salt, and identified; the mother-liquor of these crystals smelt strongly of the peculiar odour of "Almaguer bark." The actual analysis is as follows:—

Quinine sulphate	0·34 per cent.
=Quinine...	0·255 „
Cinchonidine	—
Homoquinine	—
Cinchonine	0·06 „
Quinidine	0·05 „
Amorphous alkaloids...	0·39 „

The quinine was carefully identified by the usual tests.

‡ 'Flora Columbiæ,' etc. Berolini, 1858.

Homoquinine or cinchonidine I was unable to find, but the absence of this latter alkaloid is negative evidence in favour of the Remijia theory. To summarize, we have then the following facts:—(1) *Microscopical*: The evidence of Vogl as to the great analogy of the *China bicolorata* and *Remijia pedunculata* sections. (2) *Botanical*: (*a*) Humboldt's classification amongst the Chinchonas (which then included Remijias) or Exostemmas (this latter theory is now definitely abandoned on account of important botanical dissimilarities since recognized, *e.g.*, the shape of the flowers, etc., etc.); (*b*) Lambert's evidence as given in his drawings of the leaves, which bear such a strong resemblance to Karsten's *Remijia pedunculata*; (*c*) the "family likeness" between the above-mentioned rare Tolima *Remijia* and the *China bicolorata*. (3) *The chemical evidence*: The presence of alkaloids which hitherto have only been found in either Cinchonas or Remijias.

From this evidence, drawn from so many sources of so distinctive a character, there can, in my humble judgment, be only one conclusion, namely, that the "*China bicolorata*" is in reality a true Remijia, and I, therefore, suggest for the consideration of professional botanists and quinologists whether it would not be well that it should no longer occupy a position of "greater freedom and less responsibility" under the vague term "*China*,"* but that it should boldly assume its botanical "responsibilities," and be known henceforth as "*Rejimia bicolorata*."

ANALYSES OF SOME OLD CINCHONA BARKS.

BY DAVID HOOPER, F.C.S.

Among a number of cinchona barks I have recently had occasion to analyse, the results obtained from four samples of an authentic source appear worthy of publication. These barks were some which had been given by Mr. McIvor, the late superintendent of the Madras plantations, to Dr. de Vrij, in the year 1874. Dr. de Vrij, in handing them to me for analysis, remarked that he had had them by him since that time, but no opportunity had presented itself for verifying the statements made on two of the packages.

Each sample was carefully marked in Mr. McIvor's own handwriting, with the following description:—

1. Mossed bark of *Cinchona officinalis*. Contains no quinine.
2. Renewed bark of *C. officinalis*. Contains no quinine.
3. Renewed bark of *C. officinalis*, var. *Uritusinga*.
4. Renewed bark of *C. pubescens*.

The specimens were in thick single and double quills, but their physical characters were not deemed worthy of exact scrutiny. They were all in a good state of preservation.

They yielded respectively 9·9, 9·5, 9·5, and 9·7 per cent of hygroscopic moisture at 100° C., and gave, on analysis, the following alkaloidal composition:—

	1.	2.	3	4.
Quinine	0·84	—	2·04	4·13
Cinchonidine	1·13	—	2·44	1·53
Quinidine	0·46	1·99	0·38	0·06
Cinchonine	0·71	0·68	0·99	0·49
Amorphous	1 88	2·90	0·53	0·77
Total	5·02	5·57	6·38	6·98

The No. 1, although not so bad as described, is much poorer than one would expect from an *Officinalis*. No. 2 is peculiar in the large amount (2 per cent) of quinidine it contains. Mr. J. C. B. Moens, in 'Kinacultuur in Azië,' records 1·2 per cent as the maximum quantity of quinidine in several estimations of this species, and that he found in the root-bark. Quinidine in such amount occurs in a variety of *Ledgeriana* bark to which the name *Quinitifera* has been applied, and Dr. de Vrij has found in some Java plants of *C. Calisaya* a few yield over 2 per cent. The amorphous alkaloids in bark No. 2 are also remarkably high. The fourth analysis indicates a very satisfactory yield of alkaloid, both in total amount, and in quantity of quinine. It agrees substantially with the analyses of *C. pubescens* made by Dr. Paul, in the early part of this year, notwithstanding the interval of about ten years between the times of collection.

* The synonyms for this bark are many, viz., China bicolorata, China Pitoya, Ch. Tecamez, Ch. Atacamez, Pitoya bark, Tecamez or Atacamez bark, China bicoloré, Zwei farbige China, etc., etc.

I have heard, on good authority, that *Cinchona pubescens* is a fast grower and fairly constant in alkaloidal contents. Several cuttings have recently been planted in the Nilgiris, and the result will be looked forward to with some interest. Among the large number of cinchona barks that will be candidates for a place in the new pharmacopœia, the *pubescens* species certainly possesses many recommendations in its favour.

In conclusion, I must express my obligations in being allowed to conduct the above analyses in the laboratory of Dr. W. F. Koppeschaar in the Hague.

The President, in proposing a vote of thanks to both these gentlemen, said Mr. Hodgkin was himself connected with one of the most important quinine manufacturers in the country, and therefore any communication from him was of great interest, apart from its own intrinsic value. He was connected with the firm of the late Mr. Eliot Howard, a highly respected contributor to the Conference and to the Pharmaceutical Society.

Mr. Naylor asked if Mr. Hooper's paper contained any details of the method employed for estimating the alkaloids.

The President said he did not go into details.

Mr. Elborne said the former paper was one of considerable importance. He should like to know whether this Tecamez bark was imported in large quantities, and whether it closely corresponded to the modern cuprea bark which, as at present imported was, he believed, considered to be afforded by two species of *Remijia*, the *R. pedunculata* and the *R. Purdieana*. This paper tended to show that cuprea bark was afforded by a third variety, which the author proposed to call *R. bicolorata*. Another question which occurred to him was whether this bark came from the same part of the world as ordinary cuprea bark, which he believed came from the region of Bucaramanga and certain tributaries of the Orinoco.

Mr. Plowman, in reply to Mr. Elborne, said from one of the statements in the paper it appeared that this was not a common article of commerce. It came from Tecamez, which was on the western declivity of Cotocacha in Ecuador. This was not very distant from the Orinoco, so that practically the geographical source might be said to be fairly identical. —*Pharmaceutical Journal*.

CONSULAR REPORT.—BORNEO.

BRUNEI.

The exports to Singapore are valued at $106,544, against $104,438 in 1882. The value of the sago increased to $68,411, against $64,979 in 1881, and $53,925 in 1882. The gutta and rubber exported also shows an increased value over that of 1882.

SARAWAK.

From Vice-Consul John Hardie to Acting Consul-General W. H. Treacher.

Of the principal products of the country the following figures show the quantities of each exported during the past year:—Guttapercha, 3,397 piculs, showing a gradual falling-off; Indiarubber, 1,421 piculs, showing a very important advance, to be accounted for chiefly by the rise in the value; sago flour, 110,363 piculs. Notwithstanding that the value of sago flour was gradually falling during the greater part of 1883, the production was above the average of the previous two years. The manufacture is likely, however, to be considerably smaller during the current year.

Gambier, 21,437 piculs, the quantities have not varied greatly, though the value has advanced in such a way as ought to give an impetus to greatly extended planting. Pepper, 5,370 piculs, and the productions for the current year is estimated to be as much in excess of 1883 as that year was above 1882 (nearly double); Rattans, 23,910 piculs. The Government mine at Sadong yielded 5,038 tons of coal in 1883, being an increase of 3,720 tons on the 1882 output. This was mainly consumed by the steamship "Ranee." Eighteen tons were supplied to H.B.M.'s gunboat "Moorhen," and the surplus shipped to Singapore, where a demand appears to be springing up for this coal. The export of antimony, which in 1881 amounted to 1,856 tons, in 1882 to 1,440 tons, fell in 1883 to 1,361 tons. The export of quicksilver has fluctuated considerably during the past three years, falling from 1,910 flasks in 1881 to 489 in 1882, and again to 1,400 in 1883, which in a measure is to be accounted for by the irregular seasons in which the retorting work is done, also to a sensible falling-off in the supply of ore.

NORTH BORNEO.

Towards the close of the year, however, there set in a considerable influx of Sarawak dayaks, who have penetrated far up the Kinabatangan River, near Sandakan, and have tapped valuable sources of guttapercha. As a consequence, the export of gutta during the latter half of the year was more than double that of the first half. The Sandakan gutta keeps up, so far, its reputation as being the best quality in Northern Borneo. I may remark, as a novel feature in Borneo, this incursion of hundreds of Sarawak dayaks, the dreaded headhunters of former days, who during the year nave spread themselves along the coast of North Borneo in the peaceful pursuit of trade. Several have enlisted in the North Borneo police.

With the exception of rattans of the finest quality received from the island of Palawan, nearly all the exports are the produce of the territory itself, for the establishment of the British North Borneo Company's enterprise has had the effect of cutting off the Sulu trade from Labuan without attracting it appreciately to its own North Borneo ports, the reason being that two of the British steamers wheih now trade to Sandakan continue their voyages on to Sulu and carry the trade direct to Singapore. Sandakan continues to be by far the most important port of trade in North Borneo.

The trade of North Borneo is all carried to Singapore, with the exception of an insignificant portion, which finds its way to Hong Kong in a subsidised steamer, which makes a voyage about once a month. During the year all import duties were abolished, with the exception of those on spirits, wines, &c., tobacco, and salt.—*London and China Express.*

PLANTING IN JOHORE.

COFFEE—TEA—COCOA—CARDAMOMS.

(*From an ex-Ceylon Planter.*)

About six years ago coffee planting commenced in Johore, and coffee Arabica was the kind tried, but, as you are possibly aware, it has turned out a failure. There are many *now* who say that they never believed it would succeed from the first (it is easy to be wise after the event), and some of the pioneers have come in for a good deal of blame, because they insisted on giving Arabica a fair trial. I think they were quite right in doing so, as even now there are some good large patches of coffee Arabica to be found on some of the estates, which would be considered fine even in Ceylon. I may here state that the failure of coffee Arabica was not due to any neglect on the part of the pioneers, as the estates were *well* opened, being roaded, drained and holed in a most thorough manner; indeed, the wonder is how such good work was done, considering the many difficulties the planters had to contend with in a new country.

When it was found that coffee Arabica was not a success, the majority of the estates opened were planted up to some extent with Liberian coffee, and I am glad to say this kind promises to make good all that was spent and lost on Arabica. The first Liberian planted in Johore was an experimental patch of about five acres, I think, put in by H. H. the Maharajah, who from the first has done everything in his power to assist and encourage the planting enterprize in his territory. The experimental garden is about three miles inland from the town of Johore Bahru, and was a piece of old abandoned gambier land, overgrown with lalang grass (illuc); yet a finer field of Liberian coffee I venture to state can be seen *nowhere*. The majority of the trees are from 8 to 10 feet high and bushy in proportion, being, as a rule, beautifully shaped, and are simply overladen with crop. I dare not attempt to give an estimate of the crop on this patch, as I am afraid your readers would not credit the statement, but I may mention that a gentleman told me in all good faith that he had taken nine catties of clean parchment from an average tree, and he was of opinion there was as much left. The trees are planted 12×12, so you can easily arrive at the rate per acre. Adjoining the coffee there is a field of tea, also belonging to H. H., from which most excellent samples of made tea have been taken, and, on the other side of the road, there is a cacao clearing under natural shade, which promises to [do] well. In this clearing there are a few cardamom clumps which are now producing fruit, the first which have fruited in the Straits, I am told, on both sides of the road from Johore to the garden. There are clearings of Liberian growing well, and beyond the garden there are two or three estates, in all about 300 acres. I believe there are at least 1,000 acres under Liberian coffee in Johore, and about 300 acres are this year giving their first crop, the greater portion being in the Batu Pahat district, which is about 80 miles from Johore Bahru, up the west coast. There, stores are being put up, and two of Walker's pulpers are at work, crop coming in quite fast enough for the limited supply of Tamil labor which the planters have at their command. I may here state that *Tamil labor* is all that is wanted to make Liberian coffee a perfect success in Johore. Chinese labor can be had pretty easily and is excellent as far as heavy or contract work is concerned, but Tamils are required where crop has to be picked. The Straits Government have just passed the Indian Immigration Bill, so there is every reason to hope that H. H. the Maharajah will now be able to arrange with the Indian Government for the importation of Indian labor. Leaf-disease seems to have little or no effect on the strong healthy trees, only on the weak trees does it seem to have any hold, but as these are few and far between, it has hitherto done little or no harm.

In Singapore a company has just been floated, called the "Chasserian Land and Planting Company, Limited," capital dols. 25,000, in 500 shares of dols. 500 each; the object being the purchase of a large tract of land near Singapore, belonging to Mr. Chasserian. A large portion of this is under tapioca and 100 acres are planted with Liberian coffee, from 2 years to 10 months old. I believe it is the intention of the Company to open up the greater portion of the land with Liberian, and certainly from the appearance and growth of the coffee already planted, there is every reason to think that it will pay *well*. The clearing referred to is really a splendid sight, and Mr. Chasserian deserves every credit for the way in which the work has been done. The Company is to be congratulated in having secured his services as Manager.—Local "Times."

OLIVE CULTIVATION IN TURKEY.

Consul Heap, of Constantinople, in his last report, states that olives grown in Turkey receive little cultivation after the young trees reach maturity. At the end of the autumn, or early in winter, a trench of two to three feet in diameter, and from eighteen to twenty-seven inches in depth, is dug round each young tree, and filled with manure, more or less rich, according to the age and strength of the tree. The manure is well covered with soil, so as to prevent it b ing disturbed, and to keep it as long as possible in the position best fitted to feed the roots of the tree. The ground between the trees is generally neglected. The olive tree generally comes into full bearing about its twenty-fifth year when it has been grown from slips, but when grafted it yields abundantly between its eighth and twelfth year. In both cases it continues to produce largely, every alternate year, for about fifty or sixty years, and if cultivated it will continue to yield, though less largely, up to the age of one hundred years. Under ordinary circumstances a young healthy tree that has reached maturity will produce about eighty-two pounds of fruit in a poor year, and with careful cultivation the same tree will yield in a good year double that quantity. The trees vary in yield every alternate year. An acre will contain 120 trees, and each tree will yield an average of 100 pounds of fruit, so that the produce per acre will be about 12,000 pounds, and as it takes about sixty pounds of fruit to produce one gallon of oil, the yield per acre would be two hundred gallons. When olives are intended for pickling, a small portion is plucked while green to be pickled in that state, but the larger portion of the fruit intended for preserving is gathered when it has fully ripened and has turned black; in Turkey it is preferred in this state, and there is a very large consumption of black pickled olives. To preserve black olives for the table, the fruit is packed in casks or boxes with a large layer of common salt, three quarters of an inch thick at the bottom. On this is laid a layer of olives, about two and a-half to three inches in depth, upon which a light covering of salt is sprinkled, and so on until the cask or box is filled, the upper layer of salt being deeper than the others except the lower one.

The staves of the cask are left loosely bound to allow the bitter water from the olives to drain off. In preserving green olives, the fruit after being washed is packed in cases in its natural state. The casks have a small hole bored in the bottom to allow the water to run off slowly. They are filled with olives to about three inches of the top, and the cask is then filled to the brim with fresh water once in twenty-four hours, until the bitter taste of the fruit has almost passed off. The hole in the bottom is then plugged, an aromatised pickle is poured on the fruit, and after the pickle has taken effect, a little oil is added, to soften the olives and reduce any bitterness that may remain in excess of what is required to give them piquancy or an agreeable flavour. In extracting the oil, the method practised in the interior of Turkey is the same as was employed in the earliest ages. The fruit is collected in a large receptacle near the mill where the crushing is done; this mill is simply a large circular shallow tank with an upright beam in the centre, which runs through a large stone and serves as a pivot around which the stone revolves. A horse harnessed to a horizontal pole attached to the stone sets it slowly and laboriously in motion. An improved apparatus has lately been introduced; this consists of two stones attached to the horizontal pole, and which are dragged round with it. When a sufficient quantity of the fruit has been thrown into a tank the machine is set in motion, and a man precedes the horse with an iron pole to push the olives under the stones. After a short time, about two gallons of water at boiling heat are poured in to assist the action of the stones, and more is added as required, until the mass acquires the consistency of a thick paste. The mass is then put into a large jar and conveyed to the press, where it is kneaded with more hot water into a square cloth of coarse material, which will bear the greatest power of the press without bursting. The paste is then formed into a square flat mass, the cloth being folded neatly over it, and tied with a string attached to each corner, and it is then replaced in the press. The press is turned down by means of a hand lever, and when more power is required, a rope is carried from the lever to an upright rotary beam at some distance, which is rapidly turned. The oil and water which are expressed run into a trough roughly hewn from wood. This trough is divided into two parts longitudinally by a partition, which comes up to about two inches below the level of its sides, so that when the oil and water run in together on one side of the partition, the oil coming to the surface floats over to the other side, while the water is conveyed away by a pipe, placed at the level at which it is desired to maintain the water within the trough. After the press has been screwed down as far as it will go, it is loosened, and hot water is poured upon the pile to wash off any oil that may remain on the cloths, and they are kneaded without being unfolded. More boiling water is poured upon each package, and they are again placed in the press, to be again removed, and undergo for a third time the same process until no oil remains. The oil comes out a light green colour, and is poured into a large jar near the press whence, after depositing any water or dirt it may contain, it is poured into skins. It is next emptied into large earthenware jars four or five feet in height, where it remains for at least two months until all impurities are deposited.—*Journal of the Society of Arts.*

THE CORAL INDUSTRY.—The best coral grounds yielding the most and best coral are still those on the Algerian coast, fished for that purpose from the middle of the 16th century, the others being the coasts of Sicily, Corsica, Sardinia, Spain, the Balearic Isles, Provence. Over 500 Italian boats manned by 4,200 men, are employed in the coral fishery, 300 of these boats being from Torre del Greco in the Bay of Naples. The quantity gathered by these 500 boats amounts in all to about 56,000 kilogrammes annually, valued at 4,200,000 lire; that by other boats, Spanish, French, &c., to 22,000 kilogrammes, at 1,500,000 lire—total for the year 78,000 kilogrammes at 5,750,000 lire. The taxes paid to the Government for the liberty of fishing on the African coast are very high, 1,166 lire per boat for the summer season, and half as much for the winter, so that in consideration of the toils and risks undergone, the profits are but very moderate. The gross gains per boat may be set down at 8,000 lire for the season, and the expenses at 6,003 lire, leaving only 1,967 lire net profit. In Italy are 60 coral workshops, of which 40 are in Torre del Greco alone, employing about 9,200 hands, mostly women and children. The principal markets are Germany, England, Russia, Austria, Hungary, and Poland, a large part going to Madras and Calcutta.—London *Times.*

TWIG TRAINING.—It is often the case that a young tree, or a branch of it, makes growth in some crooked or unsymmetrical direction, and so becomes something of an eyesore if nothing worse. It is always desirable that the stem of a lawn or orchard tree shall be quite straight and erect. Now, just before growth closes for the season, it is time to rectify this fault of shape most easily. To straighten the stem stick a well-sharpened rod into the soil close to the collar and on the elbow side of the crooked stem. This rod, which now stands vertically, and exactly close to where the stem should be if erect, pushes the bent stem still further over, but string tying it to the rod in as many places as are necessary to secure straightness will make all erect and shapely. This seems a simple thing to do, and it is so, yet it is rare to find the staking up a tree effectively or securely done. Ill-directed branches can be held in place by stakes placed to suit and securely fixed for tying to. The advantage of doing the work now is that the wood is now forming and hardening, and in a week or two the shoots—held in place like a broken limb in splints—will be set and the stakes no longer wanted. At this season, too, there are rarely high winds to displace or loosen the stakes. They should be no larger than is just necessary for the required strength, because with small rods a more exact and neater direction can be given.—*W. in New York Tribune.*

THEORIES REGARDING TEA DRYING are thus referred to by "Peripatetic Planter" in the *Indian Planters' Gazette*:—Following the theory I ventured to suggest for consideration last week, a circular issued by Messrs. W. and J. Jackson has been lent to me, in which they advance another theory, this one to account for deterioration of quality *after packing.* It is true their circular is compiled to explain the merits of their new dryer, but as a theory is common property once it is published, your readers have a right to this one, and it is worth practical attention in the present search after the whole truth *re* Tea Manufacture. I quote the following passage, therefore, from the abovenamed circular:—"Experience has taught us that rolled and fermented leaves may be presented to a very high temperature of air, if such leaves are kept continuously in motion, but the danger of such treatment is that the thin filmy part of the leaf gets rapidly dried or wasted, whilst the centre stem or fibre retains a percentage of sap, and it is in this where the danger rests. The centre stem and the stalks should be dried through, and this can only be done by submitting the leaves in a stationary manner to a current of air that will both dry and bake them as well as the stalks. The tea leaves when under treatment in the Victoria machine have to traverse a space of over 50 feet, during which time they remain perfectly still, with the exception that they are automatically turned over four times in course of their continual passage through. By a peculiar arrangement of air ducts, the leaves during 3 parts of the process are submitted to a temperature of about 300 degrees, but the desiccation is completed in a temperature of about 200 which obviates the risk of burning. The machine being constructed on the Exhaust principle, doors are provided by which means the working temperature of the air can be reduced 100 degrees or more almost immediately." Though the latter part of the above quotation savours of a puff, inasmuch as it rather enters into details about the machine, it was necessary to quote it to show that the theory advanced is being made the basis of a reform or revolution—call it which we will—in Tea Drying machinery; as the principle is the very opposite of that in most of the Dryers now in use. We are evidently on the eve of a battle of temperatures, in which as a side issue will also be found a conflict between Tea dried "on the quiet," and Tea dried "on the loose."

"CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AND ENERGY."

TEA CULTIVATION.

We now give the second and concluding letter of admirable counsel, written by a Ceylon planter of varied experience, to his young friend at home meditating settlement in this island as a tea planter :—

My dear ———,—I am glad to hear you have resolved to cast your lot in with us, and "do" Tea in Ceylon. As promised then I now proceed to give you a few hints founded on observation and experience, that you may begin where I leave off, and that, if my successes have led to little, my failures at least may be of service to others :

1. Stick to your *last*. If a merchant, merchandize; if a lawyer, study your business ; if a doctor, attend to your practice. But if you determine to own estates, then change all that : first become a planter, learn your work and all about it, and then invest.

2. While not trusting altogether to one string to your bow, don't at the same time have too many irons in the fire. Find out what products suit you and your land best, then go in thoroughly for them and not fritter away time and money in every new thing.

3. Concentrate your investments. In coffee all depends on the chance weather of a few weeks, and so it was well to distribute risk, when, whether the season was wet or dry, some property would do well. But in tea, select the best locality you can, and then confine yourself to it, to the saving of much labor and time in inspection.

4. Seek an investment with capacities for large expansion. Begin as small as you like, progress as slowly as you choose, but let the land be there for future big things. In the ultimate struggle for the market, other things being equal, the largest estate will have the advantage. If means compel, rather buy a small share in a large property than entire possession of a small lot.

5. Be neither the first nor the last to open in a new district, or to cultivate a new product. Pioneering is expensive, laborious, risky work ; but when all is plain-sailing profits are small.

6. In making your selection, other things being equal, give the preference to abundance of fuel ; still more to a plentiful supply of water-power : hand-work will never maintain itself against machine.

7. Avoid block loans. Never expect tranquility, independence, or success, unless you carry your title-deeds in your pocket. The nominal value of the land itself, the risk and uncertainty of all tropical cultivation, and the high rate of the interest, only render prudent, advances for working expenses and against produce.

8. Buy for cash. The discounts by the end of the year far outstrip the interest, making a handsome profit.

9. Realize when you can to advantage, and so turn over your money. More fortunes have been made by sales of estates than by sales of crops.

10. Bright as the prospects of tea are, seemingly certain as its success, still keep a weather eye open for all natural pests and blights. With coffee leaf-disease as a terrible warning, never forget that little beginnings sometimes make great endings.

11. Cultivate for utility and not for appearance. In former days that continual tit vation to make things look nice often led to much profitless expenditure of money that could be ill-spared. Estates are kept up not for show but profit, and the first question to be always asked is : Will it pay ?

12. According to your purse have good substantial buildings when such become desirable, but don't be led astray by that *ignis fatuus*—permanency. "Sufficient unto the day," and in making buildings to outlast estates, capital is but wasted.

13. Work out the profit and loss of estate-made cattle manure at the expense of your neighbour rather than of yourself. It could never be proved to me that this most extravagant of manures paid when applied to coffee, and, if so, it is still less likely to pay when put to tea.

14. Fix your private income, and keep within the figure. This needs no comment.

15. Learn to know your coolies. A word in season is generally better than a blow or a checked name.

16. Give and take all the information you can. A stick-at-home is always behind the age, and if you wish to partake of the common stock, you must add to it.

17. Avoid quarrels. As a matter of policy enmity between neighbours and unpleasantness with officials do not pay; and the more you are in the right, the more you have been wronged, the more *charitable*, as St. Paul teaches, must you be. *The injured may forgive, the injurer will never.* At the same time, that the violent and the malignant may not have everything their own way, with the harmlessness of the dove combine a little of the wisdom of the serpent.

18. Take all reasonable care of your health, for without that there will be neither pleasure nor profit.

19. Lastly, do not altogether overlook as the world too often does, that old scriptural precept: "*Haste not to be rich*" There are things more valuable than riches, and self-respect is better than gold.—I remain, &c.,

---

After past experience, even within the leaf-disease epoch, of the "great expectations" (by no means realized) based on planting operations in Ceylon, we are aware how distrustful home critics are apt to be of a series of papers apparently all on one side. It cannot be said that the above writer, however, does not fairly put his case and hold the scales evenly. But we are really obliged to the planter who sends us the following letter, which, of course, was written without reference to what has appeared on the subject within the past few days. No one can say after reading "Moderation"'s letter that there has been no adverse criticism of tea in our columns :—

To the Editor, "Ceylon Observer."

Dear Sir,—I do not wish, and I am sure you will not credit me with any desire to throw cold water on the tea enterprize in Ceylon, but the tendency of the planter to exaggerate all that is favourable and to conceal that which is unfavourable is a feature in his character which he appears to take some trouble to develope.

If my opinion of the present position of the tea industry and of the prospects before us were based entirely on what one reads in the local papers, I should arrive at the following conclusions :—

(1) That tea is an absolute unqualified success in Ceylon.

(2) That the area adapted for further cultivation is practically unlimited.

(3) That we have no difficulty in combining quality with quantity.

Now tea is not an unqualified success in Ceylon : nor anything like it. What is the yield per acre from the gardens in the immediate neighbourhood of Nuwara Eliya ? I refer particularly to Oliphant, Mr. Rossiter's estates and Tommagong.

What is the return per acre from the Ceylon Company's places : the Hope, Labookelle and Vellaioya ?

What are results from the district of Medamahanuwara ? Has an average of 300 lb. of made-tea per acre been secured from any estate in Kalutara or its neighbourhood ?

Is it not true that in the district of Ambagamuwa a garden not a hundred miles from Strathellie has never yet

given 300 lb. an acre and that the average from a number of years has been very much less than this?

How much tea has been sent away from the large estates lying between Ambagamuwa and Yatiyantota?

Have any of the Dolosbage estates averaged more than 300 lb. an acre?

Is it true or is it not true that 400 lb. an acre of pucka tea is a nearer estimate of the average from the districts of Yatiyantota and Awisawella than the 700 which Mr. Cameron said might be expected?

That tea does pay and will pay well in many parts of Ceylon I do not for a moment doubt; but that it is all absolute success I deny, and let those who think it is make further enquiries particularly in the directions I have indicated.

Now, as regards the land adapted for further extension. A gentleman, writing a few days ago in the *Observer* signing himself "Peppercorn," seems to think that in the course of a very few years there will be one unbroken sheet of tea from the sunny shores of Kollupitiya to the frozen plains of the mountain Sanatarium. "Peppercorn" is not singular in this; on the contrary there are many equally simple. My own experience teaches me that good land is very hard to get, and that *inferior* land produces very inferior results. People are planting up old coffee estates with tea, and. if you ask them whether they are satisfied that the bushes will flush freely in old worn-out soil, they say: "Yes, look at Mariawatte, Imboolpitiya and Kadawella; if these don't satisfy you, go to Windsor Forest and so on." Now none of the estates alluded to can be accepted as affording satisfactory evidence on this point, for the reason that they were all abandoned for many years and their soil was to some extent renovated.

I believe myself that several of our old districts will prove themselves admirably adapted to the cultivation of the tea plant, but so far we have absolutely no data to prove it; on the contrary the few statistics at our disposal are unfavourable, and yet one would not gather this from the papers. Can quality and quantity be combined is a question which must naturally suggest itself to a thoughtful mind.

Mr. Taylor of Loolecondera, than whom a more intelligent, practical planter does not exist, contents himself with a very moderate yield; he does not distress his bushes and he tops the market. My own conviction is that he shows a larger profit per acre with his 350 lb. than others do with 600.

We have heard a great deal about Mariawatte lately; how that it gave 1,000 lb. an acre and that it would have given 1,500 if every flush had been taken at the proper time. No further information is vouchsafed: we are in ignorance as to the prices realized and the cost of production. Will the enterprizing proprietors of this very remunerative garden supplement the statistics they have already furnished us with by answering the following questions:—

How much tea was sold locally? How much was sent home, and under what marks? and what was the average per lb., including dust and fannings? Seeing that so much has been written about the yield, it is only fair the public should have information as to prices realized.

I heard it stated not long ago that Galbodde had given an average yield of upwards of 800 lb. an acre, and that the cost f.o.b. was 27 cents per lb. I do not believe this, but I will if Mr. Hughes tell me positively that the figures have not been exaggerated. I was also informed that this 800 lb. per acre had netted 80 cents in the London market. I *can* believe this, for the tea is very good indeed, and considering the yield, which is in the highest degree satisfactory, the result is probably unequalled; but how much of the inferior tea is sold in the country?

Aberdeen estate is, if I mistake not, somewhat steep and possesses an inferior soil. The rainfall per annum is not far short of 200 inches, and yet the yield from a certain field rivals Mariawatte. Here again further information is desirable. I should like to know the acreage of this field and whether or not similar results may be expected from other portions of the estate. I should also like to know how many leaves were plucked and the prices realized.

It is not fair to quote the yield only, nor is it fair to quote prices only: the two should in all cases be combined, so that conclusions may not be misleading.

My opinion of tea in Ceylon is briefly this.—In comparison with coffee and the hundred other things that have been tried and found wanting, it will come out favourably; but that every estate will turn out a Mariawatte or a Galbodde, or that an average yield of 300 lb. will be exceeded, taking the country all through, I do not for a moment believe.

I am quite sure that at least 30 per cent of the places already in bearing don't pay and that another 30 per cent show a very slender profit. I am also quite sure that very few people know this.

Before closing, I may say that a few more particulars respecting Abbotsford would make the very full statistics still more useful. I infer of course that tea plucked from the bushes along the roads and amongst the coffee is not included in the 110 acres. What prices were secured in the London market? How much tea was disposed of locally and what was the cost of production?—Yours faithfully, MODERATION.

As regards Abbotsford, we may say at once—and we are glad of this opportunity of contradicting unwarantable statements to which, no doubt, "Moderation" refers—that the statistics published, as was plainly stated, referred only to the 110 acres regularly planted and by no means included the plucking of bushes scattered throughout the coffee or along the coffee-field roads. We shall enquire as to the other information wanted, although it may not be possible to give answers to all the questions at this time. We have no doubt that Mr. Rossiter and Mr. McLaren of Nuwara Eliya will have some information to give as to the yield of their gardens which should show satisfactory results. Oliphant, too, is surely doing better? 'Moderation" is not alone in his scepticism about the success of tea in Ceylon being so great or universal as is generally declared. Curiously enough last mail brought us the following interpellation from an old planter whom "Moderation" knows well, one of a school noted for looking well before they leap, and whom to convince, therefore, of tea being a good investment, is worth some amount of trouble. Our friend writes:—

"No one knows how low Ceylon has fallen till he tries to induce people to invest or to interest them in anything connected with it. How different it was 7 years ago! Would there be any means of ascertaining the real truth about *Mariawatte*? Of course no one will believe in 1,200 lb., and £40 is out of the question; but if 600 lb. and £20 an acre could be reasonably calculated on, then I know thousands of acres of similar soil—if soil it can be called—in a climate exactly suited: half Kaduganuawa would come in again and three-quarters of Matale rejoice, and Balakaduwa itself be a fortune to any poor if industrious planter. Mariawatte reports, however, are too good to be true. Though I well remember that when one bushel coffee per tree was talked of at Rajawella the bare idea was scouted till a special agent from Colombo was sent to confirm the fact. These were the days before desperate estimates—and newspaper correspondents were more trustworthy than they are now!—no offence meant."

We think the Abbotsford figures, now on the way to this correspondent, will satisfy him that there is more in tea than he was inclined to believe, and, as if to answer his enquiry about Mariawatte, we are able to give the following letter published by our morning contemporary yesterday:—

RESULTS OF THE MARIAWATTE ESTATE UP TO END OF 1884.

To the Editor, "Times of Ceylon."

SIR,—One hundred acres of tea were planted 4×4 in 1879, which distance apart gives 2,722 trees to the acre. At the present time there are fully 10 per cent. vacancies, so that the actual number of trees to the acre is about 2,450.

In 1882 50 acres were manured with cattle manure.
,, 1883 15 ,, ,,
,, 1884 40 ,, between August and Nov.

The manuring of 1884 cannot be taken as having affected the yield for 1884, as the estate was pruned gradually be-

tween August and November. The large yield of 1884 was obtained with 65 per cent. of the acreage being manured in 1882 and 1883.

The yearly yields per acre from the original 100 acres of Mariawatte estate have been:—

	Per acre.	Rainfall.
1880	9 lb*	inches.
1881 ...	136 „	113·82
1882 ...	312 „	117·11
1883 ...	550 „	92·77
1884 ...	1,092 „	82·72

The produce from the 100 acres in 1884 has been as under:—

Tea	lb.	109,230
Cocoa	„	1,740
Tea Seed	Maunds	20

Monthly yield of Tea.

	lb. made tea	Rainfall inches.
January ...	4,298	0·52
February ...	4,124	0·48
March ...	5,138	6·41
April ...	14,607	5·05
May ...	16,544	7·99
June ...	13,188	4·75
July ...	14,830	4·44
Augnst ...	13,236	9·56
September ...	11,132	5·99
October ...	8,102	18·86
November ...	2,611	10·01
December ...	1,393	8·63
Total	109,230	82·72

The weight of green leaf plucked per acre was close on 40 cwt. and the average yield of each tree was equal to 1¾ lb. of green leaf, or ·44 of a pound of made tea per tree.

Coldstream, January 12th. H. K. RUTHERFORD.

* First plucking began October, 1881.

It must be remembered that 1884 was one of the driest years on record on the Kandy side, and in the Gampola Valley the rainfall return was not more than 82 inches, which is well within the average of many Uva estates. In our correspondence column today will be found Mr. Johnson's report from one of the driest portions of Badulla showing an average for eight years of 71·27 inches but so well-distributed that we feel sure tea will do fairly well, as indeed is evidenced by the growth already described by Mr. Johnson. Then again from Haputale and Matale we have returns which may as well be included here:—

HAPUTALE (BELOW THE PASS).—Rainfall in 1884 was:—

	days.	in.		days.	in
January ...	15	2·32	August* ...	7	·4
February ...	9	3·64	September* ...	6	1·20
March ...	15	15·24	October ...	23	7·41
April ...	21	15·16	November ...	20	24·94
May ...	18	16·66	December ...	20	12·10
June* ...	3	1·07			
July* ...	3	1·04		160	111·19

* The average number of days on which rain fell during these months in twelve years previous were

June...	9·5 days.	Aug. ...	12·08 days.
July ...	8·42 „	Sept. ...	12·42 „

These months have therefore been exceptionally dry for Haputale. Do you consider Haputale too dry for tea? Certainly not—with 111 inches! Here is another report from a different part of the district:—

WEST HAPUTALE, 9th Jan.—After perfect planting weather, from 4th October to end of December, January has opened very dry with a parching wind which is disastrous to the tea planted (seed planted at stake especially) during December. Tea appears to grow here like a weed, and with our rainfall, which, as enclosed statement for 1884 will show, is all that could be desired for the satisfactory growth of that product, I cannot see how tea can fail to give remunerative returns, *if* we are to get anything like the good prices for our tea which many believe we will do. Nothwithstanding the long drought during June, July and August, the rainfall for 1881 has been 54·1 in. over that of 1882, and 29·83 in. over what fell in 1883. I do not think anyone is rejecting *really* good coffee for tea: but where tea is planted the coffee must be sacrificed. The theory of getting crops from the coffee, while the tea is growing, will not hold good. Our good coffee has a crop on it as much as we could wish for, little or no disease showing. Cinchona succirubra has been a great success, so far as the growth is concerned: were prices better, all would be well. The following is the rainfall for 1884:

Jan.		Feb.		March.		April.		May.		June.	
6	0·04	1	1·50	3	2·93	3	0·82	5	0·71	28	0
14	0·01	2	1·20	13	0·88	1	1·33	6	0·87		...
15	0·03	3	0·72	14	1·25	6	0 19	7	0·77		...

The average of the three years here is over 115 inches, so that, looking at the distribution of the rainfall over the months, a better climate for tea could not in our opinion well be desired. From Matale we have the following:

MATALE EAST, 9th Jan.—I enclose a memo. showing the rainfall here for the past 6 11-12th years. With reference to our future in tea: the figures show a sufficient and well-distributed rainfall, and, with our generally speaking good soil, there ought to be a good future for the old district yet. The 1883 plantings promise remarkably well, and with the present outlook are very encouraging: in several instances the growth is as fine as can be seen anywhere at the age. As regards coffee, I am afraid we are nearing the end, bug in so many cases having all but extinguished it.

Here again we have an average rainfall of fully 120 inches spend over 211 days. The old and famous coffee districts of Matale and Uva, therefore, are likely to become equally famous as tea districts. In this connection we very pleased to learn that tea is likely to be planted on an extensive scale on several Haputale properties very shortly.

COOLIES IN THE WEST INDIES.

How the depression in the sugar interest is likely to affect the indeutured labourers in the West Indies who are entitled to return passages, is thus forcibly stated by the *Port of-Spain Gazette* :—

There are some members of this community, and by no means uninfluential ones, who still cling to the belief that the sugar crisis is greatly exaggerated, and that no such commercial stagnation, much less general ruin, as is generally foretold, threatens the West India colonies, or at least Trinidad. We have cacao, coconuts, and asphalt, say these dwellers in a Fool's Paradise, and what does it matter if a few sugar planters, and *rich* West Indian merchants on the other side are compelled to abandon their propertiesor perchance to compound with their creditors? Others will take their places, and that very soon, and if meantime cacao, coconuts and pitch, and the local possessors of capital, are somewhat heavily handicapped, matters will soon right themselves and Trinidad become as prosperous as before. Such false views as these have been much encouraged by the fact that hitherto, both in England and the West Indies, the "Sugar Crisis" has been discussed from a purely financial point of view, and we frankly admit that were it possible to increase our other exports, say fourfold in twelve months, then financially the "Sugar Crisis" might not prove so disastrous in Trinidad. But even were this impossible output miraculously rendered possible, it would, though lessening the financial strain, offer not the very slightest solution of the many and great social and political problems, so closely interwoven with the sugar crisis and which are even now pressing only too prominently to the front. One of these, perhaps the chief, is what are we to do with our labouring population? Can we find them work? and if not, where are they to get food? Every man who knows anything of the subject will agree with us that if there be no improvement in the price of sugar—(and the overproduction renders such a thing under ordinary circumstances impossible)—sugar estates in the West Indies will be, if not totally at least gradually abandoned, and the commencement of such an abandonment will certainly be within the next nine months, it may be sooner. Will the cacao and coconut planters and pitch exporters be ready then to take over the indentured coolies? Will they pay the return passages of those of them who are entitled to such? And what of the thousands of labourers and artisans who are employed on sugar estates? We need scarcely say that they will not, for the simple reason that, as is well known, neither cacao nor coconut cultivation requires any large number of labourers and that they are in fact already well supplied. In this view of the case it has been truly said that immigration which has hitherto proved so great a blessing to Trinidad, will, if the sugar industry be destroyed, become a lasting curse. With our hospitals and asylums crowded to overflowing, our gaols so full as to be dangerous to health, and evidences everywhere that there is not full employment to be had for the labouring population already in the colony and that in the near future the whole fabric on which "wages" depend may crumble and disappear surely it is time that the Government gave some warning to the large number of people from the other colonies who are daily arriving, and apparently in increased numbers for if not this immigration will continue and so help to swell at a later date that most dangerous of all social elements—an idle population.

PLANTING IN THE STRAITS.

TO THE EDITOR OF THE SINGAPORE FREE PRESS.

Batu Pahat, Johore, 21st November, 1884.

SIR,—In your issue of the 15th instant I notice that a comparison is drawn between Mr. Chasseriau's Liberian coffee estate and the Johore estates, which, in my opinion is calculated to injure the latter. Without wishing for one moment to detract from the merits of Mr. Chasseriau's plantation, I confidently assert that no finer Liberian coffee can be seen in the Straits Settlements than that growing on several estates at Batu Pahat, Johore. There are over 500 acres planted with Liberian coffee, 200 acres of which are now giving their maiden crop, which is *good*, both as regards quantity and quality. Two estates here have pulpers at work, and stores are in course of erection. In fact, instead of the Johore estates being a failure, as you would insinuate. *Planters* here consider them a decided success.

LIGHT-STEP.

[We are obliged to our correspondent for his correction, but it was the Coffee Arabica the article mentioned as not having prospered as was anticipated.—ED. *S. F. P.*]

COONOOR.

(From our Correspondent.)

COFFEE.—There can be no shadow of doubt that the present era in the history of coffee planting so far as concerns the industry in Southern India, and more particularly as applied to the Nilgiris, is one which will not easily be forgotten. On all sides we hear nothing but regret at the investment of capital in an enterprize which has ultimately proved not only unprofitable, but in numerous cases, ruinous. Planters are not wanting who will tell you how they wish they had speculated otherwise than in coffee-planting; how they had invested thousands of pounds in the fondly cherished hope of turning them to good account; how they had formed golden visions of future wealth and prosperity; and how, alas! all their hopes and expectations had met with signal failure and disappointment. And, to gain a practical illustration of this, one has only to visit some of the plantations, not only in Coonoor, but in various other localities on the Nilgiris, and what is the picture? The eye does not catch sight of any "new clearing," there are no signs of any extensions on existing estates, and the number of coolies to be seen at work is visibly and miserably small. Everything seems to have passed from the stage of noticeable advancement to one of palpable retrogression, and in many instances to what is worse—complete abandonment. Short crops are still the cry of owners, agents, and superintendents, who have in addition the unsatisfactory prospect of not being able to obtain any profitable return for their produce (already short in itself owing to bad seasons), on account of the glut in the London market.

In a back number of the *Lancet* I see a reference made to a plant which it may perhaps be worth the enterprize of some of our friends to experiment in cultivating; and, at the present time when coffee-planting is not only overdone but offers so little encouragement, it would doubtless be of some value in assisting planting science to introduce something new. The *Kola* seeds, called also Ombémé nuts, are the produce of *Sterculia acuminata*, and have become known to west African travellers, who state that when chewed or sucked they possess the power of rendering the flavour of water, even when half putrid, agreeable, and are believed to contain *caffeine*. The *Kola* seeds were recently made the subject of analysis, and, according to the *Lancet* have been found to contain *actually more caffeine than the best samples of coffee produced under a similar experiment.*

TEA.—The cultivation of tea is fast gaining the preference over coffee, and, though perhaps, the return yielded by the former does not compare so favourably with that (until recently) obtained from the latter, yet, there is this advantage in tea; it is not forced out of the London market by a large surplus in the produce of other competitive countries. The demand for *Nilgiri produce* is especially encouraging, and in this respect tea planters are to be congratulated that their efforts have not been in vain. Among the gardens in the Coonoor settlement, those which have gained special prominence are "Glendale," "Brooklands," "The Highlands," and the "Coonoor Tea Estate." These properties are in the most flourishing condition, and can show plants of magnificent and unapproachable calibre. This is not surprising, since, in connection with the properties are associated the names of such veteran planters as Messrs. Stanes, Kirby, and Reilly. Moreover, the various properties named are more extensive than what is ordinarily the limit of a so-called "estate." Then, the produce of these plantations is so well-known in the tea market, the very names being a guarantee in themselves of excellence in quality. I must not omit to mention here that thriving little tea estate in Coonoor known as "Glaisdale." It has no pretensions to being a "large property," but is undoubtedly second to none in its appearance and the general character of its management, and is not to be beaten any where on these hills as a paying little property. Glaisdale tea, moreover, is in high favor, and can hold its own as regards flavour and aroma, and is, in fact, preferred to many other teas in consequence of its unvariableness in quality. The demand for it is far over the supply.—*Planters' Review.*

DROUGHT.

BY B. PURYEAR, LL.D., PROFESSOR OF CHEMISTRY IN RICHMOND COLLEGE.

Have we any remedy against droughts? To no inconsiderable extent we have, and that remedy is deep plowing.

1. Deeply plowed lands receive, when rains are abundant, into their substance all or nearly all the water that falls; none or little runs off from the surface. Such lands have therefore a larger storehouse of water, from which plants may draw their supplies—crops will stand a drought better for this reason. But the farther the water sinks into the substance of the soil, the smaller is the amount which the hot sun of summer will evaporate. Twelve inches beneath the surface, the soil is many degrees cooler in summer than the surface, and hence if the soil be once saturated to that depth, much less water is dissipated and lost by solar heat. Deeply plowed lands, therefore, not only receive into their substance more water, when rains are copious, but hold this water with greater grip and tenacity.

2. A deeply pulverized soil is permeable by the atmosphere, and the atmosphere, how dry soever, always contains some aqueous vapor. In a perfectly dry atmosphere our bodies would shrivel in a very few hours into mummies; all plants would wilt and die in a day. When the atmosphere can descend deeply into the soil, the cool soil deprives the aqueous vapor of heat, and so converts into water and deposits it just where it is most needed, about the rootlets of plants. In other words, in deeply plowed lands dew is being deposited in varying quantities all the time about the roots. Here is another reason why crops stand droughts better in deeply plowed lands.

3. Water is always rising from below by the capillarity of the soil, but it rises slowly through a hard and compact soil—with ease through a deeply pulverized soil. Hence the more deeply the soil is plowed, the larger will be the amount of water drawn up from below by capillary attraction.

Can philosophy draw comfort from a drought? When the fields are dry and parched, when the water courses are failing, and our domestic animals are pinched both for food and water, and the farmers' hopes are blasted—are there no compensating advantages? We think there are, and we give them for the comfort of the despairing and despondent. During a drought the soil is collecting its forces and recuperating its energies for better work in the ensuing season. Let us see.

If from a damp cellar we take a cube of cut sugar and touch a point to water, the water will strike slowly through the mass of sugar. But if we take a cube of cut sugar made perfectly dry by exposure to the hot sun, and touch it to water, the water in a moment flashes through the lump. The difference with which the two lumps receive water is striking and obvious. The dry lump in a tenth of the time will receive ten times as much water into its substance as the moist lump. It is just so with the earth—the dry lump of sugar represents the earth in drought; the drier the soil, the stronger is the tendency of water to rise from below to the surface, where it is evaporated.

But water never comes to the surface simply as water; it must come charged with all the soluble material which it has encountered in its ascent to the surface; it brings with it the nitrates, the sulphates, the alkaline salts and compounds, which have been exposed far below to its solvent action. When a solid is dissolved in water it is no longer solid, but is as liquid as water, and must go wherever water goes. It can part company with the water only at or near the surface, where the water changes its form and becomes vapor. But these salts lately dissolved in water becomes solid again when the water is lost by evaporation. The more severe and protracted the drought, the greater the depth from which the water will rise, and hence the greater its opportunity of meeting and dissolving solids and bringing them in solution to the surface, where they are deposited for the benefit of the ensuing crop. During a drought then, that mightiest power in the universe, that exhaustless source of all power, the great sun, is drawing up from depths inaccessible to the spade and the plow, the soluble matter of the earth, and putting it where it is most useful to the farmer in the surface soil. This water as it comes up brings what the farmer needs, and only what he needs. It brings up only soluble matter, and it is only soluble matter in the soil that can feed the growing plant. The substances that the plant derives from the soil are solids ordinarily; but they did not get into the plant as solids—all come up into the vegetable circulation in solution.

Again, no mechanical reduction could put this material, brought up by water, in so comminuted a condition. It was lately dissolved, more finely divided than could be effected by the boasted machinery of our day. When the water leaves it, it is therefore in the best possible condition for solution again. It is fully and freely available in consequence of its excessive communication, far more so than if the same amount of the same fertilizing material had been ground and bolted by the most perfect machinery at our command.

A year of hard drought is sure to be followed, if the seasons be moderately favorable, by a year of plenty. The crop gets the advantage of all the soluble material drawn up and deposited near the surface during the drought of the preceding year.—*Industrial South.*

PLANTING IN FIJI: SUGAR, COCONUTS.

VATUWIRI AND ARDMORE.

(From our own Correspondent.)

From time immemorial, to use a figure of speech, it has been the custom to refer to Taviuni as "The Garden of Fiji," and in the following I propose to indicate certain of the grounds upon which its claim to the title rests. The great sugar mill at Vuna and the two great marts of commerce and exchange have somewhat overshadowed two or three of the smaller estates, and visitors have, perhaps, gone away thinking the stores and the mill were the only things at Vuna. As your correspondent I wish to dispel this ignorance, and give you items of information concerning two orthree of the flourishing small plantations on the Point. The first of these to which I shall refer is Vatuwiri, the property of Mr. Tarte. This is the most southerly estate on Taviuni, and adjoins the native town of Nakorovou, on the south, and the Wainiaku estate on the north. It contains 670 acres, of which 470 have been planted with cocoanuts, and the balance is being planted as rapidly as labor can be obtained for the purpose. In addition to this there is another property about two or three miles inland named Woodlands, which contains 316 acres, and is used as a cattle run. Around Vatuwiri proper there are substantial stone walls and a row of breadfruit trees. Many of the latter are bearing fruit. These trees have a most pleasing effect. If they were all placed in a row they would extend a distance of two miles. When they are all bearing fruit Mr. Tarte will have more than he can use, but he will find a ready sale for the balance among the Indians. I had heard a very glowing account of the nut-trees on this estate, from Mr. Tarte and others, before I had an opportunity of seeing them myself. But Mr. Tarte is a Victorian, and has come from the "golden city of Balarat," and when I have heard him talking about his nuts, I thought he was trying to sustain the credit of his colony and indulging in, what the late Anthony Trollope would call a "little blow." When I saw the nuts for myself I was forced to acknowledge that the proprietor had understated rather than otherwise the merits of his estate. I have seen most of the nut plantations in Fiji, as well as some of the best bearing districts at Lau; but I have never seen anything to equal the trees at Vatuwiri, at their age. I was taken through a field that had been planted six years before, and the trees were in full bearing and literally covered with fruit. I could stand under most of them and touch the fruit with my hand; some of them were not three feet out of the ground, and in one or two cases the fruit was actually touching the ground. Mr. Tarte has gathered 13,000 off this field. To those who have plantations 6, 7, and 8 years old, and not in full bearing, what I have written will be regarded as almost incredible, and certainly had I not seen it myself I should have grave doubts concerning the matter. I was taken through another field where the nuts had been planted only four years before, and many of the trees were covered with blossoms, and some of them were bearing fruit.

Now a word or two as to soil, planting, and cultivation. To be brief, the soil is volcanic, is very much broken, and very strong, and was very heavily timbered. It must have taken a large sum of money to have cleared the land for planting. Mr. Tarte, in addition to his stone walls, has thousands of tons of stone on the estate that he would make a present to any one who would carry them away. I have heard that some of these nuts were planted with the assistance of the crowbar. The rocks were quarried, and a hole made, and a little loose earth gathered into them and the nuts placed therein. The soil is so very strong and the rows of nuts so very regular that it does not require a very great stretch of the imagination to enable a person to believe this. The nuts are planted 30 feet apart, and there is scarcely a "miss" on the whole plantation. Mr. Tarte exercised unusual caution in selecting the nuts for planting, and to this, together with the excellence of the soil, he attributes his success. I mean no disrespect to the proprietor of this estate when I say he is a "horsey man," and knows that good sires are essential to secure good stock. He has carried out these ideas in planting his estate; only the largest, the soundest, and the best nuts were used and set to "*rara*," and when they commenced to sprout, if they did not show signs of vigor and vitality they were rejected and not planted. Cattle have done the chief work of cultivation, or rather of keeping the nuts free of weeds. When they were young they were protected by stone walls that were built around each nut high enough and large enough to be an effectual barrier to the cattle. There is every convenience on the estate as far as stock-yards, &c., are concerned, and the carrying capacity of paddocks has been increased by planting English grasses. Mr. Tarte kills two bullocks every week, and thus supplies the white residents and the Polynesians on the various plantations with fresh meat. There is a large and increasing mob of mules on the estate, some of which are to be broken in to harness immediately, to gather the nuts off the plantation, and bring them to the drying *vatas*. The proprietor has every confidence in these animals, and thinks that in a few years they will supersede horses in Fiji.

The substantial stone dwelling-house is built in a very pretty situation, on an eminence in the home paddock, and commands a view of Koro in the south-west, and Vanua Levu in the north-west. The laborers on the estate are chiefly time-expired (or free) Indians and Polynesians. There are of course the necessary outbuildings and hospital for the comfort and convenience of the labor. Mr. Tarte has a very valuable estate, and when it is in full bearing it will yield him a handsome income. At present he runs the plantation and the store, but when Vatuwiri is in full bearing it is more than likely he will forsake "soap and sardines," and concentrate all his energies on "copra and cattle" which, if I understand him aright, will be more congenial to his taste.

Ardmore belongs to Mr. McCounell, and contains about 300 acres. I believe I am correct in saying it has a larger sea frontage than any other estate on Vuna Point. It is all cleared and most of it is planted. There is a large

paddock enclosed by a stone wall which is used for grazing purposes, a part of the estate is planted with coconuts, and 100 acres of sugarcane are grown for the Holmhurst mill. The Vuna Creek runs through the estate; unfortunately it is dry except when it rains, but there is a splendid waterhole in the bed of the creek, near to the new dwelling-house, which is seldom, if ever, dry. During the recent dry weather it had a supply of water that was a boon to the cattle. Mr. McConnell was under contract to grow 100 acres of cane for the Holmhurst mill; but Mr. Hedges, when manager for Messrs. W. W. Billyard & Co., took the contract over, and thereby secured the water and barred a claim for £4,000 damages, which Mr. McConnell made against the firm for breach of contract in not taking the cane when it was ripe. The mill takes its water from the Vuna Creek; and the company has paid Mr. McConnell a small annual sum for the privilege. By taking over the contract, however, they have not only secured the water, but settled the claim for damages.—*Fiji Times.*

WOODS USED FOR TEA BOXES

[Our readers will be interested in the following correspondence, in which poor Dr. Watt of Calcutta is severely, but we think properly, rebuked by Dr. Voelcker on the question of green wood for tea boxes.—ED.]

TO THE EDITOR OF THE ENGLISHMAN.

SIR,—I have permission to send you the following reply received from Dr. Augustus Voelcker of London to the theories advanced in Dr. Geo. Watt's memorandum and letter dated Simla, 21st June and 13th August 1884, in connexion with the subject of damage occasionally sustained by Indian Teas in transit from gardens to London, which may be of interest to some of your readers.—P. PLAYFAIR, Calcutta, November 13, 1884.

39, Argyll Road, Kensington W., September 27, 1884.

Dear Sir,—I am obliged to you for the papers which you sent me for perusal and which I herewith return with thanks.

You will, I am sure, not expect me to reply in detail to Dr. Watt's criticisms upon my report. This gentleman admits himself that he has no experience in the curing of tea, and has never seen any perforated and badly corroded lead from tea chests, and also that he is no chemist, and that probably his conclusions may be wrong. Any intelligent man who has had some experience in the packing and shipment of tea can plainly recognise by Dr. Watt's communication to the *Indian Daily News* the force of his own admissions, and feel surprised that, notwithstanding, he should venture to give a pretty positive opinion as regards the primary cause of certain tainted teas. Like most persons who have but little experience on the subjects upon which they write, and no well established facts in support of their opinions, Dr. Watt indulges in rather wild speculations and untenable theories which hardly require serious consideration.

It appears to me Dr. Watt entirely fails to recognise the points at issue. The question is not to account for the damage done during shipment of badly-cured and imperfectly dried tea, but to assign good reasons explaining the fact that well-cured and perfectly crisp tea arrives in England, as regards flavour in a tainted condition when it is packed in chests made from certain green and immature woods either altogether or only the lids, in which case the lead linings in contact with such unseasoned wood frequently are strongly corroded and sometimes entirely perforated.

There is no difficulty whatever in ascertaining whether damage done to tea during shipment has been caused by the tea having been packed in an improperly cured and insufficiently dry condition. It seems to me a mere platitude to say that tea may be damaged by being shipped in a badly-cured condition. Damaged tea of that kind never arrived in a crisp, but always more or less flabby condition, and the lead, if at all corroded, shows the marks of corrosion on the inside in contact with the tea, and never on the outside in contact with the wood if the latter was well seasoned. I have examined hundreds of tea chests containing damaged or tainted teas, in which the cause of the damage could be clearly traced to the improper condition in which the tea was shipped, and in none of these cases found the lead perforated or even very strongly corroded and never corroded at all on the outside in contact with wood.

On the other hand tainted tea which is quite crisp and as far as looks go in good condition, occasionally, and of late years more frequently than formerly, is received in England in chests, the lead linings of which are strongly corroded on the sides in contact with certain woods, and the lead lining generally more or less completely riddled through.

Assuming the tea to have been well-cured and sufficiently dry and packed in chests made from well seasoned wood, it remains sound, and the lead shows no mark of corrosion. But if the same equally well-cured and dried tea is packed in chests made from certain unseasoned woods, the chances are that the tea, although crisp and good as regards looks, arrives in England more or less tainted by a bad smell. In this case the led is always corroded and generally perforated on the side in contact with the wood, and not corroded on the side next to the tea. If the body of the chests is made from well-seasoned wood and the lids or part of the lids from certain immature woods, the lead in contact with the sound wood remains unaltered, whereas the lead in contact with the unseasoned woods, which give off unsavoury smells during shipment, gets corroded and generally pierced through and through with small holes which naturally freely admit to the tea the bad smelling products arising from the decomposition of the wood.

I and other chemists have found most positively that unseasoned wood under the conditions in which it is placed in the ship's hold, or a vessel carrying a cargo of tea, gives rise to the formation of acetic acid, which acting upon the lead perforates it, and if the wood originally has a more or less disagreeable smell or produces badly smelling gaseous products in becoming rotten, such taints are readily communicated to the tea.

Now these are unquestionable facts, which no amount of special pleading or speculative arguments, based on altogether different facts having nothing to do with the question at issue, can gainsay.

The amount of moisture in the unseasoned wood of a tea chest, or only its lid, I need scarcely say, is so small that none of the moisture can find its way through the lead into the tea. There is just enough moisture in the unseasoned wood to cause its gradual decomposition and the generation of sufficient acetic acid to effect the perforation and corrosion of the lead without producing a regular solution of lead salts. These salts and the subsequently generated white lead remain on the outside of the lead in contact with the wood.

Dr. Watt makes it appear that under these circumstances a regular watery solution of lead salts must find its way into the tea, but as there is only the dampness of the unseasoned wood, I utterly fail to see how such a watery solution can be produced. Moreover, if any liquid did find its way into the tea, it would show itself plainly in the appearance and condition of the tea.

I notice that Dr. Watt states having submitted various woods to destructive distillation. In my experiments I did not submit the specimens of strong smelling woods to destructive distillation, but simply distilled them in retort with water in order to draw off and collect the volatile and bad smelling products which distill over at the boiling point of water. As Dr. Watt does not profess to be a chemist, he may probably not know what the term destructive distillation signifies, and not have submitted the woods to destructive distillation which is the process in which wood, for instance, is subjected in retorts or other suitable vessels by itself to a high temperature, and thereby resolved into a number of gaseous and volatile liquid products and into charcoal, which is left behind in the retort. Amongst the volatile products of the destructive distillation of wood is acetic or pyroligneous acid, and it is from wood that by destructive distillation crude acetic or pyroligneous acid or wood vinegar, and subsequently concentrated acetic acid is obtained. I question, therefore, whether Dr. Watt did really submit wood to destructive distillation, for if he had done so, he would have obtained an acid distillate which readily dissolves lead; if on the other hand, he distilled the wood merely with water, what is the use it may be asked, to distill wood which is in a sound condition and gives off no bad smell?

I do not understand what Dr. Watt means by curing

tea on "scientific principles." In a certain sense scientific principles are involved in almost any operations, but this is not what is generally meant by conducting a simple operation like that of the curing or dryiug of tea, which requires a good deal of care and attention and the exercise of a great deal more common sense than some scientific men, who write and talk about things of which they know little or nothing, appear to possess.—(Sd.) AUG. VOELCKER.

THE JAPANESE MANUFACTURED EXHIBITS.—We clip the following full and appreciative notice by Mr. M. Williams in the *Gentleman's Magazine* for October:—"Many of the Japanese exhibits—barrels, for example—are polished, and one of their polishing tools is the bark of a species of *Equisetum*. My readers may remember that, in March last, I described the little-known uses of the siliceous coat of mail of the dried equisetum stems that are sold in some obscure by-streets of London under the name of 'Dutch rush.' "The Japanese use another natural sand-paper which they find prepared for them in the leaves of *Aphananthe aspera*. I have no practical acquaintance with these, and therefore can say nothing concerning their practical merits as compared with our glass-paper, sand-paper, and emery-paper. As a 'wrinkle' for the uninitiated, I may add, by the way, that glass-paper is the most suitable for polishing soft wood, sand-paper for very hard wood, bone, ivory, etc., and emery-paper for metals. Dutch rush will cut either, following the smoother of these papers for a higher polish; but it is specially applicable to plaster of Paris and other similar soft material that would show ugly scratches after either of the above-mentioned papers."—*Journal of Forestry.*

IN AN AFRICAN FOREST.—Stanley noted down the following measurements of individual monarchs of this forest. The largest of eight specimens of the *Bassia Parkii*, or Shea butter-tree, measured 12 feet round; height of unbranched stem, 55 feet: others measured 10, 11, 9, 10, and 10½ feet in circumference. There were also specimens of the African silver beech, African ash, wild olive (Zygia sp. or Mkundi), the largest 24 feet circumferential measurement; whilst creepers, euphorbias, orchids, and other types of a strictly African vegetation added to the beauty of the scene. The tree chosen out of which to form one canoe was a species of the Burseraceæ Boswellia, or gum-frankincense tree, 10 feet round at the base, and with 40 feet of branchless stem, growing about a hundred yards from the camp. On permission being granted by the chief, a fine genial old man, the first blow of the axe was struck, and in two hours, with a roaring crash awakening the echoes through the deep gorge of the river, the tree fell across a high granite rock, about 30 feet square. When placed lengthways along the ground, the log measured 37 feet 5 inches; depth, 2 feet; breadth, 2 feet 8 inches. Each of the crew then became a shipbuilder, 3½ feet being allotted as one man's share; and in eight days the canoe was completed. —*Journal of Forestry.*

MEDICAL USES FOR EGGS.—Among the colonists who have recently come to this country from South Russia, the chief remedy for cuts, bruises, scalds, and burns is oil of eggs, and extraordinary stories are told of its efficacy and healing power. It is easily made from the yolk of hens' eggs. The eggs are first boiled hard, the yolk removed, crushed, and placed over a fire, where they are watched and stirred until the whole mass is on the point of catching fire. At this moment the oil separates, and may be easily decanted. One yolk yields about two drachms of oil. For burns and scalds there is nothing more soothing than the white of an egg, which may be poured over the wound. It is softer as a varnish for a burn than collodion, and being always on hand, can be applied immediately. It is also more cooling than the "sweet oil and cotton," which was formally supposed to be the surest application to allay the smarting pain. It is the contact with the air which gives the extreme discomfort experienced from ordinary accidents of this kind; and anything which excludes air and prevents inflammation is the best thing to be at once applied. The egg is also considered one of the very best remedies for dysentery. Beaten up lightly, with or without sugar, and swallowed at a gulp, it tends, by its emollient qualities, to lessen the inflammation of the stomach and intestines, and by forming a transient coating on these organs to enable nature to assume her healthful sway over the diseased body.—*Industrial South.*

MEASURING.—There are different ways of measuring big trees, some claiming pre-eminence for their altitude, and others for their girth, some for their quantity of timber, and others for the hospitality they are capable of affording to dining parties, horsemen and pedestrians, in their hollow interiors. The Sicilians claim for a chestnut near the foot of Mount Etna that it is the oldest and largest in the world. It is said that the circumference of its main trunk is 212 feet. The decayed hollow is capacious enough to admit of two carriages driving abreast through it. Its diameter is twice as great as that of the Grizzly Giant of Mariposa. The Australian record for height stands unscathed, and we can afford to give competitors a clear field for asserting their right to some secondary consideration.—*Leader.*

TEA CULTIVATION IN CEYLON.—After years of hard struggling Ceylon appears to have hit the nail on the head at last in the shape of tea cultivation. For a long time the planters earnestly worked against the failures in coffee planting, and as their hopes appeared almost exhausted, tea cultivation was experimentally tried with marked success. The cultivation of tea has now passed the experimental period and become an established industry. To read of some of the successful plantation districts, which only a few years ago were considered valueless, is more like romance than reality. A hundred acres of land, formerly a coffee plantation, recently purchased for $3,500, was leased for half that much, and now brings in a profit of about $3,000 a year, apart from the profit to the owner. This is only one instance out of a number in all parts of the island. It has been demonstrated that tea can be produced with a profit at an altitude of 4,800 to 6,000 feet. One feature that recommends itself to the consumer is the excellence of the product, its freedom from any artificial manipulation in the shape of coloring matter or any other injurious ingredient. The future of Ceylon tea is most promising, and it is probable that it will restore to the island the prosperity which for a long time has been withheld from it. The industry and intelligence of the colonists will reap their reward, for the consummation of which they have our best wishes.—*American Grocer.*

A VALUABLE PLANT FOR DRY REGIONS.—Writing from Wagga Wagga on the 18th instant our travelling reporter says:—"Mr. R. B. Wood, secretary of the local Pastoral and Agricultural Society, has shown me a letter, dated 11th November, and just received from Messrs. Roth & Collinghorne, seed merchants, of Port Elizabeth and Uitenhage, South Africa. They state that with the letter they send some seeds of a plant capable of withstanding hot weather, but no seeds reached Mr. Wood by the same post as the letter. This may, however, be due to the fact of the letter having been addressed to Mr. Wood as 'Secretary of the Murrumbidgee Wagga Wagga Agricultural Society, Brisbane.' The Post-office officials in the latter city placed 'Try N. S. W.' on the envelope, and the letter finally reached its destination. Mr. Wood intends writing to Brisbane to know if the seeds are detained there. A glance at the address and the letter will tend to show that the mother country is not the only place where hazy ideas exist regarding the geography of Australia. Brisbane and South Australia are both mentioned, but Sydney and New South Wales are altogether ignored, although this colony is the part tended to be benefited by the introduction of what is evidently a valuable grass, and for which, should it be found to grow well, Messrs. Roth & Collingbourne deserve every praise. The letter referred to runs as follows:—'We have the pleasure to offer you seeds of our native kurroo bush (Adenadrona parrifolia), the only plant that makes sheep and ostrich farming possible and a great success in this colony. It grows on bare tracts of land where agriculture is impossible for want of depth of soil and rain. The fall of the latter being only 10 inches per annum, still the merinos and ostriches are doing well, feeding only on this plant. We feel convinced that it would be a great acquisition to the dry regions of South Australia, and that it would thrive if once well established. We know of several Australian colonists who have asked for seeds at our establishment after having seen the value of this plant here. The seeds are exceedingly small, and keep their germinating power a long time. 1 lb. would be sufficient for 20 acres.' "—*Sydney Mail.*

ALOE, HEMP AND COTTON FIBRES.

The Secretary of the Planters' Association has sent us some papers, received from the Director of Agriculture, Madras, on aloe and sunn hemp fibres and Nankin cotton. The latter, like cotton of all descriptions, seems outside the range of Ceylon enterprize, labour here being so expensive as compared with Southern India, while even where soil may be suitable the seasons are adverse—the boles being injured by our heavy monsoon rains. Sir Herbert Macpherson gives a high opinion of Nankin cotton and its bearing capacity, but we have recently seen some very different opinions, the result of practical experiments. Nankin cotton, with other kinds, was tried at Jaffna over forty years ago, and, as at present advised, we cannot recommend a repetition of the experiment. As for the aloe fibre and that of the sunn hemp, it is the old story of imperfect samples and English prices below the cost of production. In connection with some disappointing experience in Ceylon, our readers can judge for themselves as to the encouragement afforded by the following quotation. Messrs. Arbuthnot & Co. of Madras reported :—

Aloe.—Part very rough and badly prepared, but all through the Fibre is useful. Value £14 or £15 per ton.

Sunn Hemp.—Very good, soft fibre and capital colour, the sample seems to have been dressed too much as it is rather towy. Value about £18 per ton.

The market for all these outside Hemps is very dull at present but we should certainly recommend shipment of such as the above sample of Sunn Hemp.

On which the Director of Agriculture remarks :—

The fibres—aloe (*Agavé Americana*), and sunn hemp (*crotolaria juncea*) were grown and prepared in the Cuddahpah District. From the Collector's letter it appears that the cost in Cuddapah of preparing these fibres was 4 rupees a maund for sunn and rupees 2-8-0 a maund for aloe fibre. At rupees 12=£1 therefore a ton of sunn would cost locally rupees 336 and a ton of aloe fibre rupees 224. As the value of sunn in London is only £18 =rupees 216 and of aloe fibre only from £14 to £15=rupees 168 to rupees 180 a ton, a trade in them is impossible unless the cost of production can be materially reduced.

If local cost with reference to London prices is so high in Southern India, we fear the case would be worse in Ceylon. But we should be glad if trials with Death & Ellwood's machines gave results calculated to induce us to modify our adverse opinion. The desiderata seem to be abundance of raw material close to the machine and a plentiful supply of water to be used with the latter when at work. The first desideratum is, of course, abundance of raw material, and the first question the cost at which it can be grown. By-and-bye we shall know the results of the South Wynaad experiments with the growth of rhea.

FIBRE-EXTRACTING MACHINES.

We publish the official award in favour of the performances of Death & Ellwood's machine at the Calcutta Exhibition. But approval is considerably qualified, and we have not yet seen a record of successful and profitable work in a practical and commercial sense. On the contrary, we find it reported that the ten machines ordered for South Wynaad, in connection with rhea culture, have, as yet, failed to come anything up to promise in quantity finished within a given time. All our wishes are in favour of satisfactory and profitable results, but we are bound to say that we have as yet no proof of such results. In an account of rhea cultivation on Glenrock estate, Wynaad, we find that the ground in which the fibre plant is grown must be dug and pulverized, terraced and irrigated. And then comes the practical test as to profit. We quote as follows from the *South Indian Planters' Review* :—

Twenty tons of green stems will dry down to about four or five tons and these will yield from 20 to 28 per cent. of clean fibre. The green stems recently treated by the Death and Ellwood Machine on the Glenrock Estate, produced little more than three per cent. of clean fibre, though the percentage elsewhere quoted is as high as from five to six. This would seem to imply that the machine is not working satisfactorily and that much waste of fibre is taking place. The waste, however, (a dried sample of which is on view at our office) is useful, as a paper material and is readily bought up to impart strength and cohesion to inferior materials employed for the same purpose. The machine has also proved inefficient in outturn of work, being unable to operate on more than 1½ ton of green stems in a day of 10 hours instead of the 5 or 6 tons promised by the manufacturers. One of these appliances cannot be expected, so poor is the experience already gained of their use, to turn out more than 100 pounds clean fibre in a day; a result which places it little in advance of tedious manual processes employed for the extraction of the fibre in China. If the Indian ryot is induced to take up the cultivation of Rhea, it is certain machinery will not be employed by him; he will prefer to dry the stems and sell them to an itineratiog or Central Company, an idea which appears to have occurred to the Linl Soie Company, who propose to employ an agent to go round, and after purchase, treat the stems on the spot where produced, by the Favier steaming process. This will necessitate the establishment of a Central Factory with portable plant. Nothing short of some such organization will encourage the cultivation of fibre plants among the conservative Indian Ryots.

But, if the machinery employed at the central factory is not capable of doing profitable work, how can success crown the enterprize? It is possible, that, with all the directions given, the machines on Glenrock are not properly worked; but it is un, fortunate that nowhere have the machines succeeded that we are aware of, unless the inventor or some person from his establishment has come to the rescue. We hope soon to receive details of the success of practical experiments, and when these reach us they will be communicated to our readers.

FIBRE-EXTRACTING MACHINE.

The following is a portion of the report of Messrs. J. W. Hanlo, and L. Liotard, on the competition of machines in the extraction of Fibres, held in Calcutta in September last:—

Messrs. Death & Ellwood's machine did not work on the days specified above, as Mr. Death, who was coming out to work it himself, was unavoidably detained on the way by quarantine regulations. As the dates specified were not a condition of the tests or of the award of price we arranged to have a test of this machine during the following week. The plants mentioned in the above table were supplied on the 28th October, and the fibres were worked out by this machine without a hitch of any kind. Indeed, the working parts are of so simple a character, of such sound material, and correct adjustment, that they leave nothing to be desired. The jet of water plays a most important part in the extraction of fibres; for the stems, after having been bruised by the beaters against the edge of the feed-table receive a very thorough treatment by the beaters on the broad jet of water, and when pulled out they are found to have been freed of all extraneous matters, leaving clean white fibre as the result. The machine is, moreover, as has been proved by the test, capable of treating all fibre-bearing plants, whether exogenous or endogenous with the same facility. A semi-portable engine of 2½ nominal horse-power supplied the motion to the double machine used at the trials. At a rough estimate 1·75 indicated H. P. was expended in driving the double machine at 400 revolutions per minute while at work. As only one half of the machine was used for the purposes of the trials, the other half ran idle. The

quantity of water required appears to be about 400 gallons per hour for one machine, but the water can be used twice or thrice over.

Taking the data obtained at the trials as a guide the out-turn of Rhea fibre from one (Death & Ellwood's) machine would be about 60 lbs. for a day of 10 hours. This assumes a percentage of 3·75 of fibre from 1,600 lbs. of green stalks. The operators were imported and to some extent trained hands, having worked similar machines in Madras where they were accustomed to manipulate *Sanseviera Zeylanica*. Still they did not seem quite at home with the Rhea stalks, and some allowance might reasonably be made on this account. At the outside an increase of one-third would, in our opinion, represent an average day's work with dexterous and diligent workmen and stalks in good condition. It was noted that the stalks supplied to the machine were not uniform; they were of lengths varying from 2½ to 5 feet; and in withdrawing the fibre of the longer stalks from the machine more waste was beaten out of them than from the smaller stems ranging up to 4 feet. The reason is simple enough: the longer stems were rather too old for the yield of fibre, and had branched owing to the crop from which the stems were cut having been grown rather openly. The addition therefore of one-third would be equal to the work per diem of 2,200 lb. of green stalks, per machine. This quantity might be expected to give at 3 per cent. an out-turn of 66lb. of good clean fibre. The value of this out-turn, at £50 per ton, would be about 30 shillings.

It should be mentioned that owing to the late date of the trials with this machine, it was not found possible to procure suitable jute stems, as the local crops had already been cut. Some stems, however, which were over from the trials of the other machines and had been lying for about ten days on the ground were tried. The machine cleaned them with ease; but as the stems had been lying exposed to the sun, the fibre obtained was somewhat stained. It is necessary, for the efficient treatment of exogenous plants especially, that the stems should be operated upon as soon as possible after they are cut. The cutting also should take place before the plant reaches full maturity, and the proprietors of Death and Ellwood's machine rightly claims that juices which contain the various gums and colouring matters in solution are then more readily removed by means of the water used. The trials certainly bear this out, for the wild bhindi, or bondheras, which are fully matured and to some extent hardened plants, cut the day previous, gave the hardest fibre.

It remains to be settled whether the machine can be worked with profit. To solve this question completely and conclusively, detailed enquiries in various directions and much time would be needed; and we would have to wait for a valuation of the fibre by experts in Europe. It does not seem to us to delay with this object either this report, or the recommendation we have to make, for the following reasons:—

(1). Although detailed statistical proofs are wanting, we have by rough calculation reason to believe that the machine can be worked with profit in this country, especially on jute, rhea, bondheras or wild bhendi, agave, sanseviera and pine-apple.

(2). The machine is already at work in Mexico, in Jamaica, and several other countries including Southern India, and yields a profit.

(3) At gardens, in factories where steam is already available, a few machines could be introduced at the minimum of outlay, as the cost of the machine alone would be incurred.

(4) Where water power is available, a turbine can be used, instead of the steam engine. When one machine is worked singly, patent safety bullock gear supplied by the General Fibre Company can be used.

(5) When natives have gained experience in the feeding and working of the machine, they will probably be able to produce a larger quantity of fibre than at first.

The three last reasons form important considerations in reckoning the prospects which may be anticipated in this country. And as several firms in Calcutta have already made enquiries with a view to making use of the machine and they seem satisfied with what they have learnt, it does not seem necessary for us to delay our report. We are satisfied that as an extractor of fibres Messrs. Death Ellwood's machine is a distinct advance in mechanism of this class, that it extracts fibres in their natural colour and in good merchantable condition, that it operates on all plants with the same facility, and that it is suited to the requirements of this country, and is likely to prove of great service to its fibre industry. On these grounds we recommend that the full amount available for the Government prize may be awarded to the General Fibre Company of London.

NETHERLANDS INDIA.

TEA CULTIVATION IN JAVA.

(*Translated from Java Newspapers for the "Straits Times."*)

By last advices from Java, the wet season had fairly set in, the rainfall judging from observations being always heaviest in the western portion of that island, thereby making the climate moist enough for successfully growing tea and cinchona, the drier climate of East Java being better suited for sugar and coffee. The prospects of tea cultivation in the former are thus set forth by a correspondent in the *Java Bode* of the 15th December:—

The tea planters here have never yet had such a heavy crop as the present one, and they deserve to have another good year, spite of the fall in the price of tea within the last few years, and the havoc wrought by the tea-bug or Helopeltis. They have spared neither pains nor expense in importing tea seeds from Assam and securing the most approved machinery so as not to be behind their rivals in India and Ceylon. It is well-known how small have been the profits yielded of late years by even the best managed Java tea estates, yet their owners do not shrink from laying out very considerable amounts in buying Assam tea seeds and the newest mechanical appliances. Their energy will probably be abundantly rewarded, for several invoices of tea prepared from the leaves of Assam tea trees planted here have already realized high prices, and, moreover, the growth of this tea variety here leaves nothing to be desired. The great increase of the yield of Assam tea both in India and Ceylon, with a prospect of still greater increase ere long, will undoubtedly again bring prices down, but, luckily, there is every chance of the Java planters being able to hold their own against the Ceylon and Indian ones. A planter from that quarter who not long ago visited Java, where he was hospitably received on many tea plantations, was quite astonished at seeing the number of Assam tea shrubs already put out here, and at the choice kinds under cultivation, for tea, like cinchona, hybridizes very easily. One of the characteristics of good kinds is length of leaf, and in that respect there is no reason for complaint here, as leaves more than nine inches long are by no means uncommon. Machinery too has had a share in bringing about the prosperity which tea planters are now perhaps to experience after years of adversity. The first rolling machines were brought into use years ago. Now they are found everywhere, while drying machines too are highly appreciated. For machines doing the work of hundreds of natives, we are indebted to British planters, whose practical minds soon became aware of their desirableness and necessity so as to admit of manual labour being substituted by machines on productive estates, hence, among them, inventors arose like Jackson and Kinmond, who found out machinery which may with confidence be ranked among those most ingeniously put together in our time. In other respects too, they are leading the way for us, such as in discovering a chemical process for giving prepared tea leaves the flavour and strength determining their value. It is my opinion

that, as is the case with cinchona cultivation, chemistry in this way may play an important part, with a sure prospect of success, where knowledge and experience combine to further a branch of industry which finds employment for thousands of natives and yields a large revenue to the State. There is hence every appearance of the tea estates doing a good business at least within the next few years, which, I repeat, they deserve to do owing to tea planters having derived fresh energy from the adversity gone through instead of giving way to despair. Should even prices fall, which may assuredly be taken for granted, it will be found that apparently planters here work under more advantageous conditions than is the case in Ceylon or India. I say apparently, because information from there cannot always be relied on, for often out of speculation or to keep up the credit of a threatened firm or bank, fictitiously high figures are put forward. Thus it turned out on closer examination, that the fallen Oriental Bank, to keep up the credit of its tea plantations, often by means of agents itself bought in, at fabulously high prices, the tea produced there.* But I am digressing. Our planters seem to have the advantage in soil, which, in Java is so fertile that production here on a given area is greater than in India or Ceylon. Moreover, as is said by Mr. Money, the Java planters are in advance of the British in effective cultivation of the soil and especially in the art of pruning tea plants.† On the other hand, against this must be set the fact that the economic condition of the Ceylon, but not the Assam, planters gives them a decided advantage over those in Java. Mr. N. P. Vander Berg has calculated how much tea planters here and in Ceylon pay altogether in taxes per *bouw* of land, and though I cannot call to mind the figures exactly, I think they amounted respectively to 13 and 14 guilders per *bouw*. Add besides to this the better and cheaper means of transport in Ceylon, and people will, like us, come to the conclusion that here also the Government should rather strive to lighten than increase the pressure of taxation on the tea growing interest.

The same correspondent also says that Java *cinchona* planters have been greatly disappointed by seeds from Government plantations bought at high prices proving of such inferior quality that, in one instance, out of 25,000 sowed only 3,000 came up. Sometimes even plants raised from them turn out in the end to be of almost valueless varieties, the consequence being that planters prefer cinchona seeds from private plantations.

Advices from Batavia to the 24th December show that *sugar growing* in Java is in such a precarious state, that the Batavia Chamber of Commerce has had to memorialize the Governor General to remit taxation pressing upon sugar growers, and to lower railway freight rates for their benefit, as the only means to save them from ruin. The Chamber draws the following picture of how matters stand with the sugar growing interest there :—

"The gigantic growth of the beet sugar industry has had a deadly influence on prices in consequence. A life and death struggle is going on and, notwithstanding that the yield of cane sugar from Java estates has also increased of late years, signs of the decline and decay of the industry in general are showing themselves. What will be the consequences should as may now be feared on good grounds, the struggle end to the disadvantage of cane sugar? The large capital required for carrying on estate operations will henceforth be raised with difficulty. Several plantations which could not meet the demands on them have already had to stop working. Gradually more will follow, while only a few happening to be more favourably situated, where cheaper labour and lower ground-rent keep down considerably the cost of the raw material, will be enabled thereby to drag on working for a few years longer till they too, overcome in the struggle, will be driven from the industrial field and thus make widely known the disappearance of the industry. This is no exaggeration, your Excellency; at the present state of sugar prices, banks can with difficulty go on supplying capital, especially now that the end of the crisis cannot yet be forecast. It would betoken short-sightedness to count upon better times for the present. The struggle for existence will go on long enough to wreck the Java sugar industry, for it must end in that when on the one side protection is enjoyed while on the other side not only protection is denied but burdens are laid on, heavy enough in good times but now co-operating in hastening the approaching fall. Grievous indeed is it, in such times as these, to hear the Colonial Minister proposing to levy further taxation on sugar estates which are not under contract with Government. The sugar industry at this moment may best be likened to a sick man whose state is precarious and almost hopeless. Hence, when his hopeless condition is so well-known, it is cruel, instead of administering a strengthening remedy to the patient, to extinguish the last sparks of energy on which his only chance of recovery depended. The cries of distress from the dying industry were already heard in all directions, when it was suggested to the parliament in Holland to raise more revenue from sugar growers, or at least to take steps for doing so at some future time, no matter what the future might prove to be. Sugar is now so low in price that only specially favourably situated estates can be worked at a profit. Enlarging on this then is in our opinion superfluous. At the rate of 8½ guilders per picul for No. 14, few buyers make their appearance the only purchases made being small quantities of previously stipulated quality. The average value of No. 12 is at present 7½ guilders per picul. Such a price is only remunerative on estates where the expenses of production and transport are kept down exceptionally low. In default of buyers, the bulk of Java sugar will have to be consigned to Europe at the risk of the growers, to remain long on hand there before being realized, prices being all the while kept low by large stocks of beet sugar in the market. The protective laws in favour of beet sugar keep Java sugar in the back-ground. In Holland this is intensified by an excise enactment which has ousted our sugar from the Dutch market. Sugar estates in Java are not protected by the State in any way; on the contrary, export duties are levied on their produce, while, for example, in Germany, among other advantages, bonuses are allowed on the export of beet sugar."

A Padang correspondent of the *Locomotief* states that, owing to large numbers of stones being found in bags of *coffee* shipped from there to Holland, the police at that port are keeping a watchful eye on persons conveying that article on shipboard from the warehouses, with a view to detect the guilty parties.

DR. BEYERINCK, one of the most distinguished naturalists in Holland, has been investigating the origin of the masses of gum collecting on the limbs of certain kinds of trees, especially plum, apricot and others bearing stone fruits. He finds that the exudation is due to a disease produced by the presence of parasitic fungi; and when health trees are inoculated with the gum thus produced, they speedily contract the disorder, which is highly contagious. The disease is disseminated by the drying of the gum by oxidation, and its circulation in the wind, which thus wafts the germs for many rods, so that one diseased tree may infect a whole plantation.—*American Cultivator.*

---

* A malicious and absolutely baseless invention. The sales of tea in Ceylon have been but few, and neither in Ceylon nor anywhere else did the O. B. C. ever purchase tea. We cannot be surprized at these inventions of foreigners, when we notice the untrue statements about Ceylon sent to the *Indian Planters' Gazette* by one of its correspondents here.—ED.

CARGOES OF TEA FROM CHINA.—Between 8th and 30th Dec. nearly four million pounds of tea were exported from China to Britain. What has been the largest quantity sent from Ceylon in one vessel? Not more than 100,000 lb., we suppose. But from China we see that the "Gleneagles" steamer took over three-quarters of a million of pounds, the exact figures being 759,124. The "Cyclops" took 665,000, and the "Massilia" P. & O. steamer 660,451. The day is coming when similar cargoes of tea will leave Colombo harbour, before the northern arm is completed.

CARBOLIC ACID.—We are in receipt of a pamphlet issued by Messrs. Calvert the manfacturers of Carbolic acid in its various forms. The pamphlet specially treats of the value of Carbolic acid as a manure, and, as such, it is, we consider, worthy of the attention of sugar growers. We are not prepared to say that it is the best manure that can be recommended to planters and farmers, but from the results obtained in other countries it is evident that the subject of its application to our sugar lands is one which deserves the attention of those interested in reodering our fields more fertile.—*Mackay Standard.*

[Carbolic acid as an insecticide and a fungicide we know, but how is it used as a manure? An overdose of this substance at anything like the usual strength would surely make short work of the vitality of trees. What is the form and what is the cost of carbolic acid as a manure?—ED.

THE TEA TRADE.—Continuing its remarks upon the state of the tea trade, the *Produce Markets' Review* says:—"The facilities which bankers give by advances in China or here, and the readiness with which produce may be realized by consigning to the large brokers in London, no doubt form a vast improvement on the system of old days, when the first price of tea could not be ascertained, nor the profits on it at all estimated, owing to the existence in the hands of the same merchants who exported tea of a large importing trade into China from this country, and the mingling with it of a considerable banking business both direct and through India. All this has more or less passed away, but that which we referred to in our article of last week was the reckless speculation of lato years by those newly entered into the trade in tea, apparently without any sufficient consideration of the condition of the market and, at any rate laterly, at a period when a heavy drop in price was impending. It may have been that those who have thus operated in tea have been driven by necessity to continue, and that the one transaction provided funds for those which had passed, and that the loans which could not have been met at any one time were carried on by fresh advances on fresh transactions. That which we specially wish to point out, however, is that our market customs favour these proceedings, and that the system of the buyer paying a deposit is one of extreme danger, at times when speculation is rife and prices are falling. That the buyers should pay a deposit at all is surely a reversal of all ordinary trade rules, unless a complete transfer is made by the seller to the buyer; but in the case of the tea trade no goods are handed over until the entire value is paid, the deposit being but a payment on account. There is great danger that the buyer, after paying the deposit, might find that bankers who had advanced on the produce to the seller could demand successfully the entire value of the tea before parting with the warrants, leaving the buyer to claim on the seller's estate for the deposit already paid as best he might, in case of failure. Not only this, but in case of a rise in value, or an over-advance on the part of the banker, it is quite possible that, until the banker's entire claim is satisfied, even if that claim be heavier than the market value of the goods, the buyer would not be able to obtain possession; and thus he might not only lose interest by delay and litigation, but also the loss of value and sale, and the deposit already fruitlessly paid. The fact is, that the break down of the old tea monopoly has been succeeded by much speculation, and our market rules want revision. There is no need for deposits, there is no need for weight notes or warrants; but the healthy alteration in system of rapid realization by public sale, and of moderate advances by bankers on produce in China, is all to be hailed a fast avourable change.

THE JAPAN TEA ENTERPRIZE is not asleep, as will be seen from the following paragraph:—

The Tea Industry Superintending Establishment at Kobe is about to dispatch special correspondents to New York, San Francisco, Chicago, and Canada, where Japanese tea is largely exported, to report on the tea trade. The correspondence is to begin with the commencement of the next tea season.—*Choya Shimbun.*

THE HALF-YEARLY REPORT of the S. Paulo railway, to 30th June, states that, owing to a large quantity of coffee having been detained in the growers' hands, the gross receipts show a small decrease when compared with those of the corresponding period of 1883, notwithstanding the traffic was the largest ever carried by the company, while the working expenses were slightly less. The coffee crop for the coming season is estimated at 120,000 tons.—*Rio News.*

THE BRAZIL COFFEE CROP.—The *Brazil and River Plate Mail* of December 13th notes:—That the *Gazeta*, of Piracicuba San Paulo, predicts that next year's coffee crop will be shorter than any for a period of ten years. For this our contemporary offers the following reasons:—1. That the last crop was large and the trees are exhausted. 2. That the experience of the current year has been very irregular, there having been many dry months where there should have been rainy ones. 3. That great injuries have been sustained from frost. Of course such statements must be accepted *cum grano salis.*

THE CINNAMON MARKET.—A well-known cinnamon estate proprietor writes:—"Will you please publish the enclosed report on the state of the cinnamon market for th edification of those who by their persistent advocacy of monthly sales have succeeded in bringing prices lower than they ever were before?"

Cinnamon.—It will be remembered that at the usual August auctions (no sales having been held since May), the trade put a direct question to the selling brokers as to future sales, and whether they might assume that quarterly sales would be the rule in future, as they would then know how to act. The brokers interested in the intermediate sales made no demur to this assumption on the part of buyers, and, on tacit understanding, the auctions went off with spirit, at advanced prices nearly all grades, and there was a feeling of relief that the antagonism between some of the importers, and the buying trade generally had terminated. In spite of this nearly 1,500 bales were thrown on the market at the end of September, 950 being sold chiefly at a *decline* of about 1d to 1½d per lb. on August rates, while at the end of October more than 1,500 bales were again forced on unwilling buyers; 600 bales changing hands at a further decline of about 1d per lb. on September prices. The result of these proceedings has been to derstroy all confidence in the trade, and, when it was announced at the beginning of Monday's sales by the first broker selling that further auctions would be held in January (X'mas holidays intervening), the feeling of the trade was exhibited in the question put by one of the largest dealers: "Perhaps, you will inform us what advantage merchants have derived by holding monthly sales!" This feeling resulted disastrously for sellers, for, of the 2,044 bales catalagued, about 1,000 bales only sold were at a further general decline of 1d to 2d per lb. on October prices, four-fifths comprising:—"Firsts" 7½d to 9½d; "seconds" 6½d to 8d; "thirds" 5d to 7d; "fourths" 4½d to 5d per lb.; fine grades were neglected. We regret that more firmness was not shown by sellers at the commencement of the auctions, and the priced catalogue sent will enable you to judge how the sales went. Under these circumstances, we considered it our duty in the interests of our constituents not to sacrifice their cinnamon, and, consequently withdrew nearly the whole of our imports. We shall lose no opportunity of effecting sales privately if fair rates are offered. Quotations are now lower than at any former period. We enclose a very full market report from Messrs. James Cook & Co., to which we beg your special attention. —London, 28th November 1884.—FORBES, FORBES & Co.

COCA (OR CUCA) AND COCAINE.

THE NEW AND VERY VALUABLE ANÆSTHETIC.

What with the coco-palm, the cocoa (properly cacao) plant, and now the new aspirant to notice, coca, confusion is likely to be worse confounded We recently published a translation from the French of a paper on coca, and in the periodicals which have since reached us we have found a large amount of matter referring to the drug, some of the articles being couched in extravagant terms, such as that "the leaves are worth their weight in gold." This is said in consequence of the discovery that the alkaloid derived from the leaves and called *cocaine* is a local anæsthetic, or producer of partial paralysis, its use being specially valuable in facilitating operations on so delicate an organ as the eye is. The plant is already abundant in South America, has been naturalized over the tropics and seems easily produced, so that properly prepared leaves will soon be plentiful and cheap. Excepting that it is not a creeper, the plant, in its general character and properties, seems greatly to resemble the betel vine, and we would suggest a thorough analysis of the leaves of the latter plant, to ascertain if it possesses the same or a similar alkaloid. The indefatigable Mr. Thomas Christy of Fenchurch Street, London, has written several communications to our paper respecting this new drug and has sent us specimens of its leaves in a prepared state. The following is Mr. Christy's latest letter :—

"The price of 'Cucaine' has kept up, and we have sold during this week at 20s per gramme (15½ grains).

"There is a question as to the amount of fermentation that the leaves should be subjected to prior to their being kiln-dried, but as I sent you out a sample of the very best Bolivian leaves, it will only be a question of trying to imitate them for a standard. We know of some leaves that have been treated last week which have only yielded 0·18 per cent.

"There has been a discussion here this week, and it is thought best for many reasons that this important drug should take rather a different name to the 'Coca,' and most people interested in it have agreed to call it 'Cuca,' as there is no doubt it will come largely into use.

"In growing 'Erythoxylon Cuca,' it may be found that this plant will run to flower rather than to leaf. It will amply repay the planters to send people round to pick off the flowers. I don't know that the flowers will have any value, but if twigs and old leaves abound, it will be advisable to boil them down with water for the sake of the green extract. To this is added a small percentage of alcohol to keep it from going bad. The extract from Bolivia has been sold here at as much as 120s per lb. and the market is now nearly cleared. I think this will show you that every part can be utilized."

We find the following paragraph in one of our exchanges :—

An important medical discovery which has been made by a Vienna oculist named Koller was on 20th November publicly demonstrated before some scientific men. Dr. Koller has found that one drop of cocaine—the extract of the cocoa leaf—if dropped into the eye renders it totally insensible, thus enabling operations to be performed without pain. Dr. Jellinek has further found that a drop of the extract produces the same effect on the larynx, a point of the utmost importance in diphtheria and other grave throat diseases. Dr. Schrötter made use of the cocaine last night in operating on an old polypus. The operation was performed with complete success in five minutes.

We need scarcely say that if, besides facilitating surgical operations on the eye, the new alkaloid is found to be potent for the removal or dissipation of the membrane so fatal in cases of diphtheria, the drug may well be lauded as worth its weight in gold. We often recognize Mr. Christy's hand in the *Planters' Gazette*, and from a late number of that periodical (which would do well always to acknowledge *its* sources of information) we quote as follows :—

"A month ago, when at Brooklyn, U. S. A., some hard foreign substance found its way to the pupil of my eye, causing much pain and inconvenience. I went with Dr. William Thallon, of Clinton Street, Brooklyn, to Dr. Prout, an oculist, also of Clinton Street, for relief. After examination, Dr. Prout poured two or three drops of Cocaine (I think a two per cent. solution) on the eye and let it remain there for about three minutes, when he poured on some more and allowed that also to remain for some time.

"Under the influence of the anæsthetic the eye became cold and seemingly dead, and the foreign substance was removed without my being aware from sense of touch that an instrument was being used upon the sensitive organ. Dr. Prout said that had the Cocaine not been used the operation would have been a painful one. I experienced no pain either from the anæsthetic or from the operation. The eye was naturally weak for the rest of the day, and then quickly returned to its normal condition."

The day after this letter appeared there were two from London physicians stating that Cocaine was now in frequent use in operations both for eye and throat diseases. One of them, Dr. A. St. Clair Buxton, says:—"In reply to your correspondent in your issue of today, I beg to inform him that Cocaine is attracting the attention of a great number of surgeons in this country. For operations on the eye and throat the active principle of Erythroxylon Coca bids fair to prove a most useful anæsthetic. If your correspondent will look at the current number of the *Lancet* he will find mention made of the Muriate of Cocaine by Mr. C. Bader in connection with eleven cases of operation on the eye. Mr. Lucien Howe describes the physiological effects; Dr. Prosser James speaks of the drug in cases of laryngeal trouble, and Dr. Felix Semon mentions it in reference to similar cases.

"In ophthalmic surgery especially we shall hail the new painkiller with joy, if experience brings to light no drawbacks in its use."

On the 27th ult. the following from Mr. Thomas Christy, F. L. S., appeared in the same journal:—"I am glad to see from the letters in the *Standard* of 24th and 25th that our English surgeons are now aware of the great value of Cocaine for operations connected with the eye. In the *Pharmaceutical Journal*, as far back as 1879, the experiments made by Dr. Von Ansep in the Physiological Institute at Warzburg are recorded. I have been deeply interested in the plant producing the Coca leaves. I showed in "New Commercial Plants," IV, p. 43, that Erythroxylon Coca was a plant well worthy of cultivation by our planters who have so long been desirous of helping out their failing crops of coffee, &c., with new products.

"It may not be generally known, but the leaves of Coca are in themselves of the greatest value, enabling writers and brain workers to continue at work longer (and to obtain sound and refreshing sleep) during times of pressure. I have used them myself in this way, and have been happy to be the means lately of enabling many engaged in intellectual work under great pressure to complete their engagements.

"In Bolivia they make a most delicious liqueur of Coca, I was fortunate enough to obtain a few bottles some years back with some seed. These seeds produced plants which are now growing in my hothouses. There is however, some difficulty in preserving the leaves, as they are somewhat like tea, apt to damage easily, and lose their active principle."

So that the leaves of coca are, like the fruit of cardamoms, not only valuable as a medicine, but as an ingredient in "a delicious liqueur." Who would not grow such a plant? The *American Grocer* brings us the following sensational paragraph on the subject of the new anæsthetic :—

The new anæsthetic, hydro-chlorate of cocaine, mention of which was made in our last issue, is a very costly preparation, which thus far has been prepared at Darmstadt,

We find in one of our dailies the following information bearing upon its uses and cost:—

To say that an object is worth its weight in gold is ordinarily considered an exaggeration sanctioned by usage. A far more valuable standard of comparison might be found in the drug cocaine. Eighteen carat gold is worth about $16 an ounce. A recent importation of cocaine cost $8 a gramme or $224 an ounce. An apothecary's pound of this substance would therefore cost over $3,500. It is obtained from the coca-leaf to which the nations of South America ascribe the most wonderful strengthening powers. It is said that by chewing this leaf and swallowing the saliva which is mixed with its juices they can travel an incredible length of time without other food. Cocaine, which is manufactured from this leaf, is a coarse crystaline powder, although the crystals have no distinctive and definite shape. In color it is a pale yellow, and much resembles a high quality of brown sugar. It is used principally in operation upon the eye. It deadens the nerves temporarily and thus supersedes the use of chloroform. For an operation a four per cent. solution of cocaine is used. Such a solution costs $10 an ounce, and only a few drops are necessary. Cocaine has, however, the same effect upon all parts of the mucous membrane, and its use is extending. If, for instance, a small grain be placed upon the tongue it will soon produce a peculiar numbness, and deaden any sensation of pain. Large chemical houses in this country have recently attempted to manufacture the drug, and although they have not been successful in placing it in the market, they hope soon to do so. The price will then probably be considerably lower.

Another American periodical, the *Independent Journal*, also notices the new drug, though the notice is of a more sober character, the leaves being represented as selling in the New York market at $54 per lb., or say about R120 or R130. The notice is as follows:—

The price of coca leaves in this market has remained quite steady since their importation has been engaged in by several houses. Formerly the supply was irregular and the price made to suit the whim or avarice of the importer, who knew that he could realize any price he chose to ask, imports being made only as sales were effected, the article having no steady demand. As the merits of the leaves became better known the demand for them increased, and they became a regular article of trade, and supplies were kept constantly on hand with the price averaging about fifty cents per pound. Although the active principle of the coca leaves was discovered in 1855 it was not manufactured or used, it being simply looked upon as an interesting chemical discovery. During the earlier months of the present year experiments were made with the leaves, their active principle extracted, and this in turn has been experimented with and found to possess anæsthetic properties, which makes it valuable in ophthalmic surgery. Indeed, wherever it is desirable to employ local anæsthesia cocaine is found to answer the requirements better than any of the drugs or chemicals heretofore employed for the purpose. Although it is now not more than two months since this property of the coca alkaloid was made public, the demand for the leaves has increased to such an extent that the price has been advanced fully one hundred per cent. The best quality of leaves are most in demand as the percentage of alkaloid obtained from the inferior grades has been found unsatisfactory. As the price of the leaves in Peru has also advanced fully thirty per cent. since the increase in the demand it is possible that prices will go still higher, until such time as more attention is given to the collection of the leaves by the natives. The higher prices will doubtless stimulate the gathering of the leaves, and we have no doubt the supply will be found ample to meet the increased requirements.

Of course, the demand for the leaves has excited the attention of planters in Ceylon, who are ever on the *qui vive* for profitable "new products," and Dr. Trimen has received so many letters on the subject that he has suggested to us the republication of his article from "Medicinal Plants, by Drs. Bentley and Trimen,"—a very beautifully illustrated and most valuable book, we may state. The article was written in 1876, and now Dr. Trimen writes:—

"When I came here in 1880, I found this shrub abundant in Peradeniya Gardens, having been introduced from Kew in 1870. It thrives well here, flowering irregularly, but several times a year, the pretty pale yellow flowers being followed on some trees, but by no means all, by the small scarlet fleshy fruit each containing a single seed. It also grows and fruits well at Henaratgoda Garden. The seeds have been frequently advertized for sale at the Gardens. In our climate the plant grows to a greater height than that given in my description, to quite eight feet high, and the flowers have a sweet, faint, honey-like scent. I should expect it to grow well at any elevation up to 5,000 feet here." So that the plant is well established in Ceylon, and its zone, according to Dr. Trimen, is only less circumscribed than that of tea—extending from sea level to 5,000 feet. As in the case of other plants yielding alkaloids, the richness of the leaves in the active principle will probably be in proportion to elevation of site of growth. We should think the mode of cultivation would closely resemble that of tea and coffee, except that the coca plants should be wider apart, while it remains to be proved if pruning would be beneficial. The process does not seem to be adopted in South America, but the fact is not conclusive. Dr. Trimen's article is preceded by a carefully coloured drawing, showing the pretty China-tea-like plant as a whole and its botanical parts separately. The botanical name *Erythroxylon Coca* (Dr. Moore makes the distinctive name *Peruviana*), is, it appears, derived from the Greek for redwood. while coca means "*the* plant," *par excellence*. Other South American names are *Cochuco* (which might well be adopted, so as to save confusion), *Hayo* and *Ipadu*. For the full botanical description, we must refer to the article, as it will be found reprinted on page 625, merely saying here that what somewhat reminded us of a small-leaved China tea bush Dr. Trimen compares to a black thorn, the very plant the leaves of which are said to be used to adulterate China tea. The bark is wrinkled and purplish brown in colour. On the Andes its habitat is from 2,000 to 5,000 ft. elevation, and it is found in Brazil and South America generally, but scarcely ever as a wild plant. The plantations, called "cocals," are formed on the steep warm declivities of mountains, the forest being cleared for the purpose. The plant was not introduced into England much before 1870. When Dr. Trimen wrote in 1876, this plant had not been included in the British, American, or Indian Pharmacopœias, but if its claims as now asserted can be sustained, it will no doubt soon find a place of honour in the list of officinal plants. At the period of the conquest of Peru the leaves were used as they now are. The leaves are gathered at maturity and dried slowly in the sun. (Query, if the hot-air tea driers may not improve the quality?)

The leaves must be thoroughly dried, but not too rapidly. They are packed in bags, and no doubt this accounts for much deterioration; we would suggest their being hermetically packed as tea leaves are, or in tin cases as Dr. Trimen recommended. The produce is said to be 900 lb. of leaves per acre, spread, we suppose, over the two or three harvests which occur in the year? The value when Dr. Trimen wrote was calculated at 1s to 5s per lb, the total production being estimated at 40 millions of pounds. The prepared leaves are perfectly flat, not curled like tea, and they give out the combined odours of hay and chocolate. They vary in quality from somewhat aromatic and bitter, to disagreeably bitter. The chief ingredient is the alkaloid called cocaine, and like our own betel the active principle is improved by the addition of lime. The leaf is stimulant and narcotic, and the Indians exist for long periods by merely

chewing it. It is also credited with preventing difficulty of breathing in ascending high mountain. The medicinal qualities attributed to it are numerous.

Every Indian carries with him a bag of coca leaves and a gourd or calabash with lime and wood ashes. The lime, apart from other properties, promotes the flow of saliva. Travellers in South America, from Poepping to Markham, have been emphatic in their praises of the strengthening properties of coca; but, like other articles of the same class, it is injurious when taken to excess. Habitual chewers develop symptoms resembling those of confirmed opium-eaters, and are liable to hallucinations similar to those in *delirium tremens*, while in extreme cases confirmed idiotcy has supervened. Mild infusions promote digestion, while excess leads to congestion of the brain. Dr. Christison of Edinburgh obtained varying results and Mr. Dowdeswell negative effects from coca, but the varying qualities of the preserved leaves may account for such varying results. As the gathering and preparation of the leaves are of chief importance, we quote the following passage in full from Dr. Trimen's valuable article :—

Collection, Preparation, and Commerce.—Much care is taken in the gathering, drying, and preservation of coca, as its activity and value depend in a great measure on its mode of preparation. Some differences in detail occur in the collection and preparation of coca in different districts, but as a general rule the processes are as follows:—The leaves are gathered as soon as they have arrived at maturity, at which period they are bright-green on their upper surface, and yellowish-green on their under surface; and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by the hand, with the twofold object of preventing them being crushed or bruised in the process; and also so as not to injure the young leaf-buds which are left behind, for the purpose of obtaining a second crop of leaves. They are then carried away in baskets, and spread out on paved surfaces, or on the floors in the courts of the houses, or sometimes on woollen cloths; and dried slowly in the sun. This operation requires great care, for if the leaves be dried too rapidly, they lose their odour and green colour; and if stored away before they are thoroughly dried their colour is also changed, and they acquire a disagreeable odour and taste. In some districts the leaves are occasionally trampled over while they are damp, under the impression, it is said that they thus acquire a delicate flavour and smell; but also, probably, to preserve their flatness in the drying process. After being dried, the leaves are either stored in barns or huts; or packed in bags or bales, in which they are pressed by treading, and are thus transported to a distance. These bags or bales (*cestos*) appear to differ very much in size, their weight being variously given by authors at from 24 to 150 lb. As the properties of coca are injured by transportation, and often by keeping, it would probably be best preserved in cases or packages lined with tin, or at least in well-closed pots to protect it from air and moisture. The produce of coca per acre in a good harvest is estimated by Weddell at about 900 lb.; and in some districts there are three or even four harvests in the year. The total produce of coca is probably not less than 40,000,000 lb., which estimating the value on an average at the low price of one shilling per pound (for the best qualities yield at least five shillings) in the countries in which it is produced, would represent a total value of £2,000,000; so that coca is by no means an unimportant article of commerce, and its production is moreover described as being very remunerative. It is chiefly exported from Lima.

Later information than that contained in Dr. Trimen's article, we find in a paper extracted into the *Independent Journal* from the (American) *Medical Record*, the author being Dr. Oliver Moore. This we have also quoted in full in this number, and we may now say that the writer uses the alternative name *cuca*; states that it is *found wild* in Peru and Bolivia, and that it is cultivated *on high altitudes*. The leaves, which resemble those of the tea plant, are plucked at from one year old to 40 years. But we must quote this passage :—

They are considered ready for plucking when they break on being bent, and are gathered in March (after the rainy season, this being the most abundant crop), in July and in November. Good samples of the dried leaves are uncurled, with a deep green upper and a gray-green lower surface, and have a strong, tea-like odour. Bad specimens have a brown color and a smell resembling camphor. The flowers of the plant are small and white, and are succeeded by red berries.

The seeds are sown in December and January; the cultivation of the plant gives employment to thousands of the people, and the annual production in Bolivia and Peru in 1864, was estimated at two million five hundred thousand dollars in value.

The green leaves are spread on coarse woollen cloths and dried in the sun, then packed in bags, which, in order to preserve the efficacy of the leaves, must be kept free from dampness. The leaves are worth in Peru seventy-five cents a pound, and cost here one dollar.

If the "here" in the above means New York, Dr. Moore must have written before the great rise in price. It is computed that eight millions of the human race use annually 30 million pounds of the leaves mixed with lime. Two men buried in a mine are said to have lived nine days on the small quantity of coca leaves they had with them, and the miners believe that the leaves chewed and cast upon the ores render the latter tractable. The praises of the leaf figure in the poetry of Cowley. The leaves were used in the religious ceremonies of the Peruvians. Bouchardat considered coca almost equal in therapeutic value to cinchona. The leaf was first introduced into France in 1869 by Joseph Bain, a pharmacist who manufactured from it an elixir and a wine. Cocaine seems to have been discovered by Niemann in 1855 and its physiological action is said to be identical with theine, caffeine, &c. It is, therefore, deemed probable that extracts of tea or coffee might be equal in effect to cocaine, but see what Dr. Squibb writes in extracts further on. Dr. Alexander Bennett (of the United States) tried cocaine on animals and found it acted most powerfully and poisonously on the various organs. So different are the results in different hands. But the important statement in Dr. Moore's paper is :—

The experiments with the cocaine hydrochlorate, by applying it to mucous surfaces, as the conjunctiva, has been known of only about one month, and, as far as I know, the American surgeons have been among the first to operate with its use. Since then many more have been made, with almost universal success.

Another American writer, Dr. Squibb, wrote a very elaborate article on Cocaine* which we find taken over into the *Pharmaceutical Journal* of Dec. 1884, from *Ephemeris* (no doubt an American periodical) of October. This article deals mainly with the chemical aspect of the matter, shewing how very minute a quantity of the active principle can, by any ordinary methods, be obtained from very large quantities of leaves. Cocaine seems to have always been very expensive and rather rare in the American market, Merck of Darmstadt having been the principal maker. The sudden and large demands following on the discovery of the valuable anæsthetic qualities of the drug had sent up the price considerably. Dr. Squibb writes :—

The hydrochlorate of cocaine, which is the salt so much in demand, is put up by Merck in vials of 1 gram each, and these before the excitement were sold at wholesale at 2·50 dollars each, or about 16 cents a grain. But the price did not remain long at this figure; it rapidly advanced to about 8·00 dollars per gram, or over 50 cents per grain before the main supply was exhausted—and the latest prices heard of were 75 cents per grain, or 1·25 dollar per fluid drachm for a 4 per cent. solution.

It is exceedingly rare that a novelty in the materia medica is so easily and so quickly tried, and still more rare that

* Given further on.—ED.

one is found that is so very definite and so very important in its results, and the future utility of which is so quickly and so easily established, and hence the importance of a prompt supply of the substance if possible. The great probability that only small quantities of so rare and costly an alkaloid would be either on hand, or in process of making in Europe, and that the demand there would exhaust that and keep it exhausted for some time to come, leaving but little available for the United States, while the demand would be much greater in the United States than in Europe—induced the writer to try to bridge over the difficulty temporarily, by trying to learn how to make it in small quantities for further investigation of its uses. It was fully recognized that, like many other similar articles, it cannot be made permanently in the United States because of the enormous tax there on alcohol and ether, these appearing to be the chief solvents used in making it, unless some cheaper solvents can be found for its extraction and purification. Another difficulty to be met was that of getting good coca leaves to make it from. In assaying coca leaves the best results the writer has ever obtained were about ·26 per cent. of cocaine, and this is in accordance with other published assays, while upon a manufacturing scale the best results published seem to have been about ·2 per cent. of the hydrochlorate, or 2 grams per kilogram, and this from the best leaves.

The Doctor then proceeds to detail his by the means successful experiments to manufacture no article. He states:—

Merck's hydrochlorate of cocaine came in the form of a damp, amorphous, granular powder of a rather dusky white colour,—several shades off from being colourless. It has a peculiar ethereal odour, and a mildly bitter taste, the taste being very promptly succeeded by a benumbing sensation.

Abundant experience has shown that in all ordinary cases of eye operations the instillation of two drops intothe eye, and after waiting ten minutes, three drops more, will in ten minutes after the second instillation, give an anæsthesia which will continue complete for about ten minutes, and pass off in about twenty minutes, leaving no irritation or other bad effects. Doubtless weaker solutions will be required for therapeutic purposes, but these can be easily made extemporaneously from the stronger one. Use has been made of both a 2 per cent. and 1 per cent. solution in painful conditions of the eye with entire relief, but the applications have to be frequently renewed, as the effects pass away rather rapidly. Such solutions are of course very easily made from a 4 per cent. solution as needed, without any necessity for keeping more than the one stock solution.

The effects of cocaine as a local anæsthetic are wonderful, and it is still more wonderful that these effects should not have been before discovered. There have been several independent investigations of its physiological and therapeutic effects. It has often been dropped in the eye, and its mydriatic effect was well-known. It had also been used for spraying the fauces in laryngology to lessen the sensitiveness to the use of instruments, and its discoverer, Niemann, and many since have noticed its benumbing effects upon the tongue; but it remained for Koller to discover its effects as a local anæsthetic, and thus within a week's time to raise it from an obscure position in the list of useless alkaloids to an importance and utility hardly exceeded in the materia medica. It had been repeatedly given both internally and hypodermically, and found to require large doses, often repeated, to produce any appreciable effect. One grain of it will give complete anæsthesia of an eye for ten or fifteen minutes, fifty times, and yet the same quantity taken into the stomach has hardly given an appreciable effect, and this quantity represents about 400 grains of good coca. Thus there seems to be very little relation discoverable at present between its general effect on the economy and its local effect. As an agent correctly and properly classed with tea, coffee, guarana, etc., as a nervous stimulant it was so indefinite in effect—at least when of poor quality—as to lead some close observers to doubt or deny its stimulant action, when now it suddenly comes into view in the opposite rôle of the most powerful nervous sedative ever known short of absolute destruction of issue. The action of heat, or of chemical cauteries which destroy the tissues, do not more completely obliterate sensation than this agent, and yet it does not appear to interfere with vitality at all, does not irritate at all either primarily or secondarily, and its profound action appears to be followed by no hurtful reaction. With such a character so suddenly acquired, it seems practically to have sprung into existence fully armed for a great amount of future good in the art of medicine. Already it has been applied to many purposes beside those of ophthalmology, and extravagant and improbable statements in regard to its effects are circulated, and it has also, doubtless, been often misapplied, but it is far too well tried to be classed with the doubtful novelties of the time, or have an uncertain importance in the future. The difficulty now is to get it for application.

Our readers will thus see that the same romance attends the discovery of the really valuable property of this drug "worth its weight in gold," as surrounded the gold discoveries in California and Australia, and we are justified in concluding that the earth we tread on and all that it produces teem with important secrets which when discovered will subserve the health and well being of man. To quote again: —

Another curious point is its differing activity upon different persons. A piece of paper ¼ of an inch square, wetted with a 4 per cent. solution and laid upon the tongue, will give a pretty distinct sensation of the size and even the form of the insensitive or numb spot within one minute on some persons, while in others it will take twice and three times that length of time, and give a more faint impression, while in one case met with it gave no impression at all. Bibulous paper wetted with the solution and dried may be carried in the pocket, certainly for some days, and probably for an indefinite period, and when cut and laid upon the moist tongue will promptly produce the characteristic effect.

The opportunities for an extensive use of the agent are very numerous and important. Its principal effects so far have been for the most part upon mucous membranes, or upon surfaces denuded of cuticle, and it is not known how far it will affect unbroken skin or the tissues beneath. Some superficial neuralgias are said to have been benefited by the application of the solution, and upon this the writer has suggested the use of the paper wetted with the solution and then dried—the paper to be cut of the size of the superficial pain to be wetted and applied to the part, and then to be covered with oiled silk a little larger than the paper. The results of such applications have not yet been heard from.

A far better preparation for such uses would be, however, an oleate of cocaine. The alkaloid unites directly with oleic acid and forms a true salt, and this salt is a principal object the writer has in view if he should finally succeed in making the alkaloid. The facility with which these oleates are absorbed by sound skin, and the depth to which they probably penetrate before being too much diluted by the circulating fluids, give, theoretically, great promise for the use of such a preparation for the relief of local pain.

In short there can hardly be imagined a larger field of usefulness than is now open for investigation by means of this new agent, and although there will be many disappointments and very much over-zealous enthusiasm, it is fortunate that but little harm can be done with it beyond the waste of so scarce and valuable a substance, as there has been no case yet reported in which any poisonous or bad effects have resulted from its use even when internally administered in grain doses.

The close relationship, if not identity, in physiological effects and popular usage of coca with tea and coffee, as a nervous stimulant, has led to the rational inference that caffeine might also prove to be a sedative or anæsthetic like cocaine, and some trials of caffeine have been published as unsatisfactory. But all the trials published, as well as those heard of from private sources, have not been so conducted as to be conclusive. When compared as they exist in coca and in tea, cocaine is about eight times stronger than caffeine, and therefore it might be expected that a 32 per cent. solution of caffeine would be required to do what a 4 per cent solution of cocaine would do, and such a solution is at present impracticable. Besides, it is reported that solutions of caffeine are irritant to the eye.

Neuralgia, although not so fatal as diphtheria, is much more general and renders many an existence almost unbearable. If, therefore, as seems probable,

cocaine turns out to be a cure for this fearful affection of the nerves, the benefit to suffering humanity will be beyond calculation great.

We have thus, with some pains, brought together the main facts connected with this "new product" and if the demand for the alkaloid continues large, we cannot doubt that the Ceylon planters will do their part in supplying abundance of the leaves in the best possible condition.

ERYTHROXYLON COCA.*

Lamarck, Dict. ii, *p.* 393 (1786).

COCA. COCHUCO. HAYO. IPADU.

Figures.—Cavanilles, Diss., t. 229; Compend. Bot. Mag., ii, t. 21; Le Maout & Dec., p. 295; Baill., Hist., pl. v, figs. 80-87.

Description.—A small shrub of 2—4 feet or more high, bushy and much branched, with a purplish-brown wrinkled bark, the young twigs smooth. Leaves closely placed, alternate, shortly-stalked, 1-2 inches long, lanceolate or oval, ratherattenuated into the petiole, usually blunt and emarginate with a small apiculus in the notch at the apex, perfectly entire, soon falling, rather thin, bright green above, paler and glaucous beneath, quite glabrous, midrib prominent, lateral veins numerous, faint, freely anastomosing; on either side of the midrib as far as a well-defined, curved, raised line less than midway between it and the margin of the leaf and extending from base to apex, the surface is somewhat concave, paler in colour and with the veins less prominent; stipules small, cauline, combined along their inner edge to form a single, triangular, acute, denticulate organ between the petiole and the stem (intrapetiolar), very persistent, at first thin, greenish, and transparent, afterwards, when the leaves have fallen, brown, stiff, and almost spinous, and marked on the back at the base by the scar of the petiole. Flowers small, on slender, drooping, glabrous stalks about ¼ inch long, 3 or 4 together in the axils of the leaves or of the persistent stipules, with several small broad bracts at the base. Calyx very deeply cut into 5 triangular-ovate, acute, glabrous segments. Petals 5, alternating with the calyx-lobes, imbricate, with a broad claw, and a broadly oval-oblong, spreading, concave, obtuse limb, pale yellow, provided at the point of junction of limb and claw with an erect scale (ligula), which is very deeply bifid with the two lobes crisped at the margins and a reflexed tongue between them. Stamens 10, hypogynous, equal, longer than the petals, erect, united at the base into a short, fleshy tube surrounding the ovary, filaments white, smooth, anthers oblong, yellow, basifixed. Ovary superior, ovoid, smooth, normally 3-celled, but usually 1-celled, the others being abortive, ovule solitary, styles 3, erect, cylindrical, green, stigmas capitate. Fruit a small indehiscent drupe less than ½ inch long, oblong-ovoid, pointed, surrounded at the base by the persistent calyx and staminal tube, smooth (furrowed when dry), red, sarcocarp scanty, endocarp thin. Seed filling the endocarp, with a thin testa, embryo straight with a superior radicle and flat cotyledons, in the axis of cartilaginous endosperm.

Habitat.—The Coca is cultivated to a very large extent in the Andes of Peru and in Bolivia and Colombia, especially in the very moist mild climate met with at from 2,000—5,000 feet above sea-level or higher; it is also now grown in parts of Brazil, the Argentine States, and other countries of South America. Though without doubt a native of some of the same districts, it is scarcely known in a wild state; Poeppig considered it so at Cachero and on the summit of the Cerro de San Cristobal in Peru, but Weddell in Bolivia only saw the cultivated plant.

The plantations (called "cocals") are always formed on the steep warm declivities of the mountains, the original forest growth being cleared for the purpose. The largest and most productive are in the province of La Paz in Bolivia. The Coca plants are said to resemble in habit small black-thorn bushes, and the nearly inodorous flowers are abundantly produced.

It is scarcely possible to mistake the leaves of Coca for those of any other plant, the two longitudinal arched lines on the under surface being characteristic. These, which are found in several other species of *Erythroxylon*, are not, as often described, veins or nerves, but folds or creases produced by the mode in which the leaves are packed in the bud. A fully grown leaf is shown in the woodcut, drawn from a specimen from Bolivia in the British Museum.

The precise date of the introduction of Coca into England we have not ascertained, but it was probably not many years previously to 1870; specimens are now to be seen in the houses of several of our botanic gardens.

Part Used and Name.—Coca; the dried leaves. It is not official in the British Pharmacopœia, the Pharmacopœia of India, or the Pharmacopœia of the United States. But Coca was in general use by the natives of Peru at the time of the conquest of that country, and has continued to be more or less extensively employed up to the present time.

Collection, Preparation, and Commerce.—Much care is taken in the gathering, drying, and preservation of coca, as its activity and value depend in a great measure on its mode of preparation. Some differences in detail occur in the collection and preparation of coca in different districts, but as a general rule the processes are as follows:—The leaves are gathered as soon as they have arrived at maturity, at which period they are bright-green on their upper surface, and yellowish-green on their under surface; and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by the hand, with the two-fold object of preventing them being crushed or bruised in the process; and also so as not to injure the young leaf-buds which are left behind, for the purpose of obtaining a second crop of leaves. They are then carried away in baskets, and spread out on paved surfaces, or on the floors in the courts of the houses, or sometimes on woollen cloths; and dried slowly in the sun. This operation requires great care, for if the leaves be dried too rapidly, they lose their odour and green colour; and if stored away before they are thoroughly dried their colour is also changed, and they acquire a disagreeable odour and taste. In some districts the leaves are occasionally trampled over while they are damp, under the impression, it is said that they thus acquire a delicate flavour and smell; but also, probably, to preserve their flatness in the drying process. After being dried, the leaves are either stored in barns or huts; or packed in bags or bales, in which they are pressed by treading, and are thus transported to a distance. These bags or bales (*cestos*) appear to differ very much in size, their weight being variously given by authors at from 24 to 150 lb. As the properties of coca are injured by transportation, and often by keeping, it would probably be best preserved in cases or packages lined with tin, or at least in well-closed pots to protect it from air and moisture. The produce of coca per acre in a good harvest is estimated by Weddell at about 900 lb.; and in some districts there are three or even four harvests in the year. The total produce of coca is probably not less than 40,000,000 lb., which estimating the value on an average at the low price of one shilling per pound (for the best qualities yield at least five shillings) in the countries in which it is produced, would represent a total value of £2,000,000; so that coca is by no means an unimportant article of commerce, and its production is moreover described as being very remunerative. It is chiefly exported from Lima.

General Characters and Composition.—Commercial specimens of coca either consist of the leaves more or less pressed together in compact masses, or of the leaves in a loose state or separate from one another. In either case the leaves are not curved or rolled in any degree, but perfectly flat. When carefully prepared the leaves are unbroken, of a fine green colour, and a delicate agreeable somewhat aromatic odour, which is at once perceptible when they are bruised, and which has been compared to the combined odour of hay and chocolate; but specimens are often met with in which the green colour is replaced by brownish, yellowish, or reddish-brown tints, and the odour lost or of a more or less disagreeable character. Coca when fresh has a somewhat aromatic and slightly bitter taste; and when carefully dried it has a similar flavour; but in other cases its aroma is lost, and it is simply bitter and disagreeable. Coca of commerce varies very much indeed in quality.

Coca has been analysed by Niemann, Stanislas Martin

* *Coca*, the native name; meaning the "tree" or "plant" *par excellence*.

Maisch, Lossen, Woehler, and other chemists; and the results of their investigations show that its principal constituents are, a crystalline alkaloid called *cocaine*, a volatile odoriferous alkaloid named *hygrine*, *coca-tannic acid* and *coca-wax*. *Cocaine* is described as crystallizing in small colourless inodorous prisms, having a slightly bitter taste; sparingly soluble in water, more soluble in alcohol, and still more so in ether; it is strongly alkaline, and in most of its reactions is said to resemble atropia. When heated with strong hydrochloric acid it is resolved into a new alkaloid *ecgonine*, together with *methyl alcohol* and *benzoic acid*. *Hygrine* at ordinary temperatures is a thick oily liquid of a yellowish colour, dissolving readily in alcohol and ether, but only partially soluble in water. "It possesses a strong alkaline reaction, a burning taste, and an odour of trimethylamin." The medicinal properties of coca would appear to depend essentially on cocaine and hygrine. Both these alkaloids seem to be in combination with one or more acids; probably the variety of tannic acid already mentioned, as the addition of lime or other alkali is said to increase to a great extent the flavour and activity of the drug. This latter fact has a very important bearing on the preparations of coca; as those obtained by the agency of milk of lime would thus appear to be more active than simple infusions or extracts of the drug; the latter are, however, frequently used.

Properties and Uses.—Coca has been used by the natives of Peru and some other parts of South America from the earliest periods. The Indians ascribe to it many and great virtues. Thus they believe that it possesses marvellous sustaining powers, and that its use enables them to undergo great fatigue and want of sleep for a long time in the absence of food. Commonly the Indians pass whole days in travelling or working without any food, but simply chew coca; but they eat freely in the evenings. It is also employed as a stimulant or narcotic in the same manner as tobacco, opium, and alcohol are thus used in other countries. The use of coca is also said to prevent the difficulty of respiration which is generally experienced in ascending high and steep mountains. The leaves are likewise regarded as a very valuable application to ulcers, boils, &c.; also to stop hæmorrhage; and for the relief of headache, neuralgia, &c. In the form of infusion coca is also employed in asthma, colic, jaundice, hypochondriasis, any many other affections. Indeed, coca is to the Indians almost a necessity, and to be deprived of it would be felt by them more than the loss of any other substance. Every Indian carries with him suspended from his belt a little bag or pouch called *huallqui* or the *chuspa*, which contains coca; and also a little bottle-gourd or calabash (*ishcupura*) containing some finely-powdered lime, or wood ashes formed of the burnt stems of the *Chenopodium Quinoa*, *Cecropia peltata*, or other plants. This bottle-gourd has frequently a wooden or metal needle attached to its stopper; otherwise the Indian also takes with him a little stick or slip of wood for the purpose of helping himself to its contents as he desires. The native takes his coca three or four times a day; and in doing so he first removes the leaves separately from the pouch and places them in his mouth, and with his tongue forms them into a kind of ball; he then moistens the slip of wood or needle in the stopper of the calabash with saliva, and dips it into the lime or wood ashes which is locally termed the *Llipta*, and presses it on the ball of leaves in his mouth. The lime is added as already noticed under the belief that it develops the flavour of the coca, and also it is said to produce a flow of saliva, which is either entirely swallowed or partially expectorated. This operation of chewing generally takes about a quarter of an hour during which period the Indians remain perfectly at rest and are silent. In some cases, however, as with post-runners, drivers, and miners, the chewing is continuous.

The extraordinary virtues ascribed to coca by the Indians has naturally excited the attention of numerous travellers, physicians, and other persons, and their opinion of its merits will be best judged of by a few references to their published statements. Thus Poeppig states that the miners chewing it every three hours with a handful of maize will do such severe work in the mine for twelve hours as no European could effect; and that an Indian runner will carry a load of a hundredweight for ten leagues over rough roads in eight hours by its aid alone. Von Tschudi and Dr. Scherzer have also given similar testimony to the effects of coca; and the former especially refers to the effect it had on himself in greatly assisting respiration, and thus enabling him to ascend the mountains with ease in hunting. Stevenson also, who for twenty years resided in Peru, and was Secretary to the Governor of Quito, states "that the natives in the mines and travelling derive such sustenance from chewing these leaves that they frequently take no food for four or five days, though constantly working; and that they had told him that with a good supply of coca they felt neither hunger, thirst, nor fatigue, and that without inconvenience or injury they could remain eight or ten days without sleep." Dr. Weddell, Spruce, Markham, and numerous other travellers and scientific observers, also attribute the same effects to it. Markham says, "I chewed coca, not constantly, but very frequently, and besides the agreeable soothing feeling it produced, I found I could endure long abstinence from food with less inconvenience than I should otherwise have felt, and it enabled me to ascend precipitous mountain sides with a feeling of lightness and elasticity, and without losing breath." Most writers, however agree, that when coca is taken in excess it produces highly injurious effects like the immoderate consumption of other stimulants or narcotics, such as fermented liquors, tobacco, opium, and Indian hemp. An habitual chewer is termed a *coquero*, and is said to be at once known "by his haggard look, gloomy and solitary habit, listless inability, and disinclination for any active employment." Weddell says its habitual use acts on Europeans more prejudicially than on the Indians accustomed to it from their early years; and that in some cases it causes a peculiar aberration of intellect, characterized by hallucinations. Von Tschudi and Poeppig also state that the result of intemperance in its use is frequently confirmed idiocy. More recently Dr. Mantegazza, of Berlin, who formerly practised in South America, from numerous experiments drew the following conclusions:—The leaves chewed or taken in weak infusion have a stimulating effect on the nerves of the stomach, and thus greatly assist digestion. In a medium dose of three or four drachms, coca excites the nervous system in such a manner that muscular exertion is made with great ease; then it produces a calming effect. In a large dose it increases the animal heat and augments the frequency of the pulse, and consequently of respiration. Used in excessive doses it causes delirium, hallucinations, and, finally, congestion of the brain. He recommends its use as an antispasmodic; for colic, flatulence, diarrhœa, and impaired digestion; in dyspeptic and all spasmodic affections; as a tonic in debility and nervous prostration; in hysteria and melancholia; as a safe aphrodisiac in seminal debility; and in other affections. Many other practitioners have also spoken in eulogistic terms of its value as a remedial agent in a variety of diseases; and the sulphate of cocaine has even been recommended as a substitute for sulphate of quinia in intermittent fevers. Dr. Buzzard, however, who tried it extensively in epilepsy and other forms of nervous diseases some years ago, obtained no striking effects from its use.

More recently the address of Sir Robert Christison to the Royal Botanical Society of Edinburgh has been especially the means of drawing attention to the alleged properties of coca. From experiments made by Christison on himself, and also from those made by several students at his request by chewing coca without the addition of the *Llipta* which he regards as useless, he drew the following conclusions:—"The chewing of coca removes extreme fatigue and prevents it. Hunger and thirst are suspended; but eventually appetite and digestion are unaffected. No injury whatever is sustained at the time or subsequently in occasional trials; but I can say nothing of what may or may not happen if it be used habitually. From sixty to ninety grains are sufficient for one trial; but some persons either require more, or are constitutionally proof against its restorative action. It has no effect on the mental faculties, so far as my own observations go, except liberating them from the dullness and drowsiness which follow great bodily fatigue. I do not yet know its effect on mental fatigue purely. As to the several functions, it reduces the effect of severe protracted exercise in accelerating the pulse. It increases the saliva, which, however, may be no more than the effect of mastication. It does

not diminish the perspiration so far as I can judge. It probably lessens the hourly secretion of urine solids." Christison made no trials of its influence on disease or the consequences of disease. It has been stated that the success of Weston as a pedestrian was due to his chewing coca, but in a letter to the *Lancet* he states that he found it rather lessened than increased his strength; in fact, it acted as an opiate and forced him to sleep. Since the publication of the above results by Christison, a series of most carefully conducted experimental observations on the properties and action of coca has been made by Mr. Dowdeswell in the Physiological Laboratory of University College, London. The results of these various trials are published by the author in the *Lancet* for May 6th, 1876, and are thus summarized by himself:—"These results, as far as they go, are negative, as many most competent to judge concluded that they would be; but contrary to the expectations of the writer, formed from published statements. It has been taken in all forms, solid and liquid, hot and cold, at all hours from 7 o'clock in the morning till 1 or 2 o'clock at night, fasting and after eating. In the course of a month nearly one pound of the leaves altogether has been consumed, but without producing any decided effect; it has not affected the pupil nor the state of the skin; it has caused neither drowsiness nor sleeplessness; assuredly it has occasioned none of those subjective effects so fervidly described and ascribed to it by others—not the slightest excitement nor even the feeling of buoyancy and exhilaration which is experienced from mountain air or a draught of spring water. This examination was commenced in the expectation that the drug would prove important and interesting physiologically, and perhaps valuable as a therapeutical agent. This expectation has been disappointed. Without asserting that it is positively inert, it is concluded from these experiments that its action is so slight as to preclude the idea of its having any value either therapeutically or popularly; and it is the belief of the writer, from observation upon the effect on the pulse, &c., of tea, milk-and-water, and even plain water, hot, tepid, and cold, that such things may, at slightly different temperatures, produce a more decided effect than even large doses of coca if taken at about the temperature of the body. What its physiological action may be, particularly on the lower animals, in highly concentrated doses, as of the alkaloid or the distillate, is another question, as it is whether the subjective effects which have been asserted may not offer a question of curious nervous idiosyncrasies."

These results of Mr. Dowdeswell's would appear to set at rest the claims of coca as a therapeutical agent. Very recently, however, a writer in the *Lancet* has again described it as a powerful nervine tonic, and recommends its use to sportsmen whose nervous system is badly adapted for steady shooting.—*Medicinal Plants by Bentley and Trimen.*

THE COCA LEAF AND ITS ALKALOID.

BY WILLIAM OLIVER MOORE, M.D.

The importance which has been attached to the alkaloid of the coca leaf during the past few days in ophthalmic surgery has led me to bring together a few facts, historic and otherwise, for the general reader, knowing that doubtless they would prove of interest.

Cuca, or coca (erythroxyion coca), as called by the natives (erythroxylum peruvianum), is found wild in the mountains of Peru and Bolivia, and is also cultivated on high altitudes. The leaf is the part of the plant in which the active principle resides. These leaves, which resemble those of the tea-plant, are gathered from plants varying in age from one to upward of forty years. They are considered ready for plucking when they break on being bent, and are gathered in March (after the rainy season, this being the most abundant crop), in July and in November. Good samples of the dried leaves are uncurled, with a deep green upper and a gray-green lower surface, and have a strong, tea-like odor. Bad specimens have a brown color and a smell resembling camphor. The flowers of the plant are small and white, and are succeeded by red berries.

The seeds are sown in December and January; the cultivation of the plant gives employment to thousands of the people, and the annual production in Bolivia and Peru in 1864, was estimated at two million five hundred thousand dollars in value.

The green leaves are spread on coarse woollen cloths and dried in the sun, then packed in bags, which, in order to preserve the efficacy of the leaves, must be kept free from dampness. The leaves are worth in Peru seventy-five cents a pound, and cost here one dollar.

The habit of the natives of the western countries of South America to chew the coca leaf, has given much interest to this plant; the dried leaves are chewed mixed with quicklime, which is said to make its flavor more sensible to the taste. In the same way the leaf of the betel-nut is used by the East Indians.

The leaves are called *cuca* by the Indians, and *coca* by the Spaniards. It has been estimated that cuca or coca is used by eight millions of the human race, consuming thirty millions of pounds per annum, by chewing the leaves made into a ball mixed with lime. The leaves are deprived of their stalks, two or three ounces of them being used during one day. It is a powerful stimulant to the nervous system, enabling the fatigue to be borne with less nourishment and greater ease than usual. A case is reported by Whittingham, in 1850, of two men being buried in a mine eleven days before they could be dug out, during which time they were kept alive by the small amount of coca they had with them.

So much vaunted is the coca as a stimulant to nervous energy, that the poet Cowley represents an Indian chief as addressing Venus, thus:—

"Our *Varicocha* first his *Coca* sent,
Endow'd with Leaves of wondrous Nourishment,
Whose Juice succ'd in, and to the Stomach ta'en
Long Hunger and long Labor can sustain;
From which our faint and weary Bodies find.
More Succor, more they clear the drooping Mind,
Than can your *Bacchus* and your *Ceres* join'd.
The *Quitorta* which this provision stor'd
Can pass the vast and cloudy *Andes* o'er."

It was used by the Indians of Peru in ancient times, being employed as an offering to the sun; it was also thought that unless the priest chewed these leaves during his ceremonies the gods would not be propitiated. It is still held in veneration, and is thought by the miners to have an effect in softening veins of ore if chewed and thrown upon them. As to the effect of this habit of chewing the leaves on the system, much difference of opinion exists; on the whole the opinion of Dr. Smith is in accordance with most of the facts. He says:—"When used in moderate quantity it increases nervous energy, enlivens the spirits, and enables the Indian to bear cold, wet, great bodily exertion, and want of food to a surprising degree with apparent ease and impunity." Sir Robert Christison, in a paper read before the Edinburgh Botanical Society, April 13, 1876, on this subject, narrates some experiments on his students and himself, showing the harmlessness of the drug.

Bouchardat states that coca has rendered to therapeutics value almost equal to the cinchona bark, classing it as a stimulant to the nervous and muscular systems, and ranks it as such with tea and coffee. He terms it also a "substance d'épargne," or that which prevents the rapid waste of tissue. The leaf was first introduced into France by Joseph Bain, a "pharmacien," about 1869, from which he made an elixir and wine. Vin Mariani, of recent introduction into this country, is made from these leaves; we have also a fluid extract, etc.

Cocaine, the alkaloid, was discovered by Niemann in 1855; its chemical formula is $C_{17}H_{21}NO_4$; its physiological action is apparently identical with that of theine, caffeine, guaranine, and theobromine. Dr. Alex. Bennett was perhaps the first to conduct a series of experiments with this alkaloid; his observations being made on the lower animals, and he concludes from these that:—1. Cocaine is a powerful poison, inducing a series of symptoms affecting the nervous, respiratory, circulatory, and vaso-motor systems, which terminate, if the dose be large enough, in death. 2. In small doses, cerebral excitement not followed by coma, and partial loss of sensibility. 3. In large doses it produces cerebral excitement, complete paralysis of sensibility, tetanic spasms, and death. 4. It paralyzes the entire posterior column of the spinal cord, *also the entire system of peripheral*

sensitive nerves; but the anterior columns of the cord and the peripheral motor nerves are not paralyzed. 5. It does not produce muscular paralysis. 6. It usually produces *contraction* of the pupils. 7. It produces an increase in the salivary secretion.

These conclusions were arrived at after experiments conducted on more than one hundred animals of different kinds. Dr. Ott finds similar physiological effects, except that he noticed the pupil *to dilate;* this is in accordance with our present experience. It is interesting to note that the neutral principles contained in coffee, tea, and chocolate, beverages so generally in use, are almost identical in chemical composition, and similar in physiological action, to cocaine; and this fact may lead us to find in either theine, caffeine, or theobromine local anæsthetic properties similar to the alkaloid of the coca plant; if so, it would be much cheaper and more readily obtained. Cocaine is a very deliquescent substance and it is hard to obtain crystals, yet by patience they may be.

The experiments with the cocaine hydrochlorate, by applying it to mucous surfaces, as the conjunctive, has been known of only about one month, and, as far as I know, the American surgeons have been among the first to operate with its use. Since then many more have been made, with almost universal success.

This mydriatic effect of cocaine is well marked and will make it a valuable contribution to our list, as ophthalmoscopic examinations can be made, and the inconvenience of atropine not be felt, the effect on the accommodation in the former being of such short duration. The chemical formula of atropia is almost identical with cocaine. The mydriatic effect of the cocaine applied to the eye in man differs from the effect noticed by Dr. Bennett in his experiments, where the drug was given by the stomach in animals, he finding a contracted pupil the rule. As to the action of the drug in producing anæsthesia of the surface both of mucous membranes and the skin, that is a point still to be worked out.—*Medical Record.*

COCAINE.*

BY DR. SQUIBB.

Cocaine and its salts have always been very expensive and rather rare in the market,—have always come from abroad, and, so far as the writer knows, Merck, of Darmstadt, has been the principal maker. A very few houses in this neighbourhood had each a small quantity of, probably, not exceeding a few grams, and this small supply was rapidly exhausted. Some buyers were shrewd enough and quick enough to get a few grams and hold them for the advanced prices which they foresaw, and such have now, for some time past, been the only sources whence any could be had. Orders to Merck, and perhaps to other makers, were cabled as soon as the excitement commenced, but up to this time, Nov. 19, only two or three small parcels are known to have been received in the United States, and it therefore seems quite probable that the demand abroad has also been greater than the present means of supply. The hydrochlorate of cocaine, which is the salt so much in demand, is put up by Merck in vials of 1 gram each, and these before the excitement were sold at wholesale at 2·50 dollars each, or about 16 cents a grain. But the price did not remain long at this figure; it rapidly advanced to about 8·00 dollars per gram, or over 50 cents per grain before the main supply was exhausted—and the latest prices heard of were 75 cents per grain, or 1·25 dollar per fluid drachm for a 4 per cent solution. The orders sent out have been numerous, and for quantities likely to be overwhelming for an article hitherto so little used. A single New York house ordered 2,000 grams, and had one customer ready to take the whole. Many of these orders are overdue but not heard from, except the two or three small lots above mentioned, and these have come in at increased prices, with notice of still farther advances. Two large houses in the United States are advertising a 4 per cent solution of their own make, and are said to be selling the solution—the one at 7·00 dollars per ounce, the other at 6·00. The salt of Merck's make, which was sold in the United States at 2·50 per gram, probably cost the importers about 2 dollars, including the 40 per cent duty, so that Merck's prices must be somewhere about 1·40 dollars per gram.

It is exceedingly rare that a novelty in the materia medica is so easily and so quickly tried, and still more rare that one is found that is so very definite and so very important in its results, and the future utility of which is so quickly and so easily established, and hence the importance of a prompt supply of the substance if possible. The great probability that only small quantities of so rare and costly an alkaloid would be either on hand, or in process of making in Europe, and that the demand there would exhaust that, and keep it exhausted for some time to come, leaving but little available for the United States, while the demand would be much greater in the United States than in Europe—induced the writer to try to bridge over the difficulty temporarily, by trying to learn how to make it in small quantities for further investigation of its uess. It was fully recognized that, like many other similar articles, it cannot be made permanently in the United States because of the enormous tax there on alcohol and ether, these appearing to be the chief solvents used in making it, unless some cheaper solvents can be found for its extraction and purification. Another difficulty to be met was that of getting good coca leaves to make it from. In assaying coca leaves the best results the writer has ever obtained were about ·26 per cent of cocaine, and this is in accordance with other published assays, while upon a manufacturing scale the best results published seem to have been about ·2 per cent of the hydrochlorate,—or 2 grams per kilogram, and this for the best leaves. Now as good coca leaves are rarely to be had in the United States or elsewhere, in quantity, at less than 1·00 dollar per pound, and often 1·25 dollar, and as a pound yields at most not over 14 grains of the salt of the alkaloid to those who have learned how to make it, it follows that the salt when still in the leaves is worth (1·00÷14=) 7 cents per grain or 1·09 dollars per gram. As the learning how to get it out is costly, and the solvents, apparatus labour, etc., also costly, there cannot be a large profit on it even in Germany at 1·40 dollar per gram, and it is therefore much better for the users of it in the United States to buy it abroad where it can be made so much cheaper. Nevertheless it seems just now worth while to try to temporarily supply a small quantity, and as the solution would be much more easily made than the solid salt, to aim only at that, and at a strength of 4 per cent. Two lots, only, of fair coca were found in the market at 1·00 dollar and 1·25 dollar per pound, and only one of these at 1·00 dollar was in sufficient quantity. The leaves were green and fresh-looking with fair odour and taste, but appeared to have been gathered and dried when small and young. They were put up in compact bales of about 100 pounds each, and looked not only much better but much fresher than any seen in the market for two years past. A preliminary qualitative testing showed the presence of cocaine in them, and they were ground to a fine powder, losing about 4 per cent in drying and powdering, bringing the net cost up to 1·14 dollar or more per pound.

Upon this powder all the published processes accessible to the writer were one after the other tried, and also some original processes, and some combinations of those of the books, occupying about a month in time and over 100 pounds of powder, with almost negative results. Some processes yielded no alkaloid at all, others only traces, while others gave a few grains which had to be used up in the testings to ascertain their identity. By this time it was suspected that the powder could hardly contain much alkaloid, although in appearance it had been of fair quality—good enough to warrant its use in the hurry for alkaloid, without taking the time for a quantitative assay. Such an assay, which should have been made at the beginning, was then made at the end of such a loss of time and material, and showed, by the assay process previously given (see *Pharm. Journ.* Aug. 23, p. 146), that the powder contained about 18 per cent, or less than two-thirds of what it should contain, and this assay showed that the process given is not well adapted to poor quality of coca, so that a better assay process had to be sought. Four other samples of coca were obtained from the market, costing 5 cents, 55 cents, 50 cents and 40 cents per pound. One the analogy of tea and coffee it was supposed that the lower grades might possibly yield nearly as much alkaloid

* From *Ephemeris*, November 1884.

as the higher; but this did not hold good in the United States, as some of these lower grades appeared to contain no alkaloid at all, while others contained too little to work with any advantage by so expensive a process or processes. So it became necessary to adhere to the young, green coca as the best that could be had.

Of all the processes thus far tried, none have been at all satisfactory, and others are still being sought out, but that of W. Lossen, of 1862, as given in Gmelin's 'Handbook,' English edition, vol. xvi., p. 300, seemed to be the best thus far, when modified in some of the details. Up to this time, however (November 19), nothing like the proper amount has been obtained from the coca, and the small return for so much expense and labour is so discouraging that if a reasonable supply from abroad could be reasonably excepted within a short time, it would be abandoned.

As it is, however, the writer still hopes to produce it when better coca can be obtained, and thinks there may possibly be cheaper solvents found for it than alcohol, ether or chloroform. Where such large quantities of a substance have to be exhausted for so small a result as 8 to 12 grains to the pound, and the alkaloid so sensitive and so easily decomposed, there is no wonder that it requires great skill to prevent its being lost in the large amount of extractive matter. Something like an alkaloid is always obtained by all the processes, but it often proves to contain very little or no cocaine.

Merck's hydrochlorate of cocaine came in the form of a damp, amorphous, granular powder of a rather dusky white colour,—several shades off from being colourless. It has a peculiar ethereal odour, and a mildly bitter taste, the taste being very promptly succeeded by a benumbing sensation. It is soluble in strong alcohol, but not appreciably soluble in strong ether. A gram of the salt gives 387·5 grains, or a little more than seven fluid drachms of 4 per cent solution. This solution is opalescent or turbid, and requires filtering, leaving several milligrams of insoluble matter on the filter, and the filtrate is not colourless, but of a greenish-yellow tint, and neutral or slightly alkaline reaction. Of this solution 10 c.c. equal to ·4 gram of the salt precipitated with solution of carbonate of sodium 1 in 5, gave a white precipitate of the alkaloid cocaine, which, dried at a low temperature, weighed almost exactly ·3 gram, or three-fourths the weight of the salt taken. It should yield, according to Gmelin (vol. xvi., p. 302), 88·78 per cent. The precipitated alkaloid is very sensitive to heat, turning brown when dried on a porcelain surface hardly above 70° C. Authorities state that when precipitated by carbonate of sodium it is not soluble in an excess of the precipitant. This may be ture, but yet a considerable proportion of the alkaloid can be washed out, by ether, from the mother-liquor from which the alkaloid has been precipitated by a slight excess of carbonate of sodium. If the carbonate of sodium does not dissolve it, the chloride of sodium, which results from the decomposition of the hydrochlorate of cocaine, does. In the precipitation with carbonate of sodium no carbonic acid is given off. The alkaloid when pure or nearly so is but slightly soluble in water, but it is quite soluble in water which holds even small proportions of the extractive matters and the salts of the coca leaves. It is easily washed out of alkaline watery solutions, provided there be but little extractive matter or alkali present—either by chloroform or ether; but with the substances just mentioned present in any considerable proportion, an emulsion is formed with both solvents that no device yet tried has been able to separate, although much time and pains have been given to the matter.

The solution of Merck's hydrochlorate in distilled water, and the solution filtered, remains entirely clear for two or three weeks, but some that is now a month old shows the usual signs of microscopic growths. But a solution made at the same time, wherein half the water was replaced by a cold saturated solution of salicylic acid, remains entirely clear and bright, and judging by analogy and experience with the salts of other alkaloids, it will remain clear indefinitely. The solution so protected has been frequently used without discoverable irritation, and from these circumstances it follows that all solutions of salts of cocaine should be so protected from change.

From what has been said it appears that a 4 per cent solution of Merck's hydrochlorate contains only about 3 per cent of the alkaloid, or 3·41 per cent of the hydrochlorate of the alkaloid, and yet this solution appears to be quite strong enough for all ordinary uses to which it has been applied up to the present time. Many ophthalmologists appear to have succeeded well with a 2 per cent solution, but they do not mention the quantities of this solution used, and it is inferred, from some experience communicated by Dr. C. S. Bull, that the quantities used must have been larger than he used, and if by this there was any loss of solution by overflow, or much loss of time in waiting for the anæsthesia, and especially if the anæsthesia was not complete, then there is no economy in the smaller cost of a 2 per cent solution. From all the experience up to the present time it seems probable that a 4 per cent solution is the best, and the only one needed, as it appears to be strong enough to produce complete anæsthesia with quantities so small as not to involve waste by overflow, or unnecessary loss of time. Abundant experience has shown that in all ordinary cases of eye operations the instillation of two drops into eye, and, after waiting ten minutes, three drops more, will in ten minutes after the second instillation, give an anæsthesia which will continue complete for about ten minutes, and pass off in about twenty minutes, leaving no irritation or other bad effects. Doubtless weaker solutions will be required for therapeutic purposes, but these can be easily made extemporaneously from the stronger one. Use has been made of both a 2 per cent and 1 per cent solution in painful conditions of the eye with entire relief, but the applications have to be frequently renewed, as the effects pass away rather rapidly. Such solutions are of course very easily made from a 4 per cent solution as needed, without any necessity for keeping more than the one stock solution.

The effects of cocaine as a local anæsthetic are wonderful, and it is still more wonderful that these effects should not have been before discovered. There have been several independent investigations of its physiological and therapeutic effects. It has often been dropped in the eye, and its mydriatic effect was well known. It had also been used for spraying the fauces in laryngology to lessen the sensitiveness to the use of instruments, and its discoverer, Niemann, and many since have noticed its benumbing effects upon the tongue; but it remained for Koller to discover its effects as a local anæsthetic, and thus within a week's time to raise it from an obscure position in the list of useless alkaloids to an importance and utility hardly exceeded in materia medica. It had been repeatedly given both internally and hypodermically, and found to require large doses often repeated, to produce any appreciable effect. One grain of it will give complete anæsthesia of an eye for ten or fifteen minutes, fifty times, and yet the same quantity taken into the stomach has hardly given an appreciable effect, and this quantity represents about 400 grains of good coca. Thus there seems to be very little relation discoverable at present between its general effect on the economy and its local effect. As an agent correctly and properly classed with tea, coffee, guarana, etc., as a nervous stimulant it was so indefinite in effect—at least when of poor quality—as to lead some close observers to doubt or deny its stimulant action, when now it suddenly comes into view in the opposite rôle of the most powerful nervous sedative ever known short of absolute destruction of tissue. The action of heat, or of chemical cauteries which destroy the tissues, do not more completely obliterate sensation than this agent; and yet it does not appear to interfere with vitality at all, does not irritate at all either primarily or secondarily; and its profound action appears to be followed by no hurtful reaction. With such a character so suddenly acquired, it seems practically to have sprung into existence fully armed for a great amount of future good in the art of medicine. Already it has been applied to many purposes, beside those of ophthalmology, and extravagant and improbable statements in regard to its effects are circulated, and it has also, doubtless, been often misapplied, but it is far too well tried to be classed with the doubtful novelties of the time, or have an uncertain importance in the future. The difficulty now is to get it for application.

One of the most interesting points in connection with it is, as to what becomes of it in action. Unlike atropine and other alkaloids its effects are very transient. Is it

as easily and as rapidly decomposed into inert substances in action as it appears to be in the process of extraction from the leaves? Or it is simply diluted as it is absorbed into the circulating fluids, and simply ceases to act from dilution?

Another curious point is its differing activity upon different persons. A piece of paper ¼ of an inch square, wetted with a 4 per cent solution and laid upon the tongue, will give a pretty distinct sensation of the size and even the form of the insensitive or numb spot within one minute on some persons, while in others it will take twice and three times that length of time, and give a more faint impression, while in one case met with it gave no impression at all. Bibulous paper wetted with the solution and dried may be carried in the pocket, certainly for some days, and probably for an indefinite period, and when cut and laid upon the moist tongue will promptly produce the characteristic effect.

The agent, for reasons given above, must always be an expensive one unless it should be made synthetically, as is not improbable,—but the expense, for many uses at least, is not so great as appears at first sight. Take its use in eye surgery as a good example. For any ordinary eye operation 2 fluid ounces of ether or more are required for an anæsthesia, costing not less than 10 cents at the least. Five minims of the 4 per cent solution of the cocaine salt gives the required local anæsthesia at a cost, after the present excitement passes, of not over 5 or 6 cents, while the time and skill required in the two applications are pretty nearly equalized. But in the one case the whole organism has to be anæsthetized for an operation of a few minutes upon a single small part, while in the other case only the part itself is rendered anæsthetic. Should the demand for salts of cocaine remain greater than the supply, and very few people be able to get good coca, or learn how to make the salts, as is not improbable for some months at least, holding the price still up to, say, 1·00 dollar per fluid drachm for the 4 per cent solution, this would give about 1·67 cent per minim, or 8·33 cents for a single anæsthesia for the eye, and a proportionate cost for other uses.

The opportunities for an extensive use of the agent are very numerous and important. Its principal effects so far have been for the most part upon mucous membranes, or upon surfaces denuded of cuticle, and it is not known how far it will affect unbroken skin or the tissues beneath. Some superficial neuralgias are said to have been benefited by the application of the solution, and upon this the writer has suggested the use of the paper wetted with the solution and then dried—the paper to be cut of the size of the superficial pain—to be wetted and applied to the part, and then to be covered with oiled silk a little larger than the paper. The results of such applications have not yet been heard from.

A far better preparation for such uses would be, however, an oleate of cocaine. The alkaloid unites directly with oleic acid and forms a true salt, and this salt is a principal object the writer has in view if he should finally succeed in making the alkaloid. The facility with which these oleates are absorbed by sound skin, and the depth to which they probably penetrate before being too much diluted by the circulating fluids, give, theoretically, great promise for the use of such a preparation for the relief of local pain.

In short there can hardly be imagined a larger field of usefulness than is now open for investigation by means of this new agent, and although there will be many disappointments and very much over-zealous enthusiasm, it is fortunate that but little harm can be done with it beyond the waste of so scarce and valuable a substance, as there has been no case yet reported in which any poisonous or bad effects have resulted from its use even when internally administered in grain doses.

The close relationship, if not identity, in physiological effects and popular usage of coca with tea and coffee, as a nervous stimulant, has led to the rational inference that caffeine might also prove to be a sedative or anæsthetic like cocaine, and some trials of caffeine have been published as unsatisfactory. But all the trials published as well as those heard of from private sources, have not been so conducted as to be conclusive. When compared as they exist in coca and in tea, cocaine is about eight times stronger than caffeine, and therefore it might be expected that a 32 per cent solution of caffeine would be required to do what a 4 cent solution of cocaine would do, and such a solution is at present impracticable. Besides, it is reported that solutions of caffeine are irritant to the eye.—*Pharmaceutical Journal.*

THE FALLING LEAVES.—Concerning an article on the above subject (p. 514), which appeared in our issue of October 25, we desire to state that the figures in the summary of analysis should have been preceded by a decimal point in each instance, otherwise they are true and consequently misleading. About utilising leaves there is not much to be said in general, it depends so much on locality. As the soil here is stiff clay or sand, I always use them (as hotbed manure mixed with dung) as manure direct from the hotbeds, or after another year, according to my requirements, and find their humus doing such good service in bettering the physical condition of the land that I do not care to destroy that part by mixing with lime or other caustic materials; but if I had a soil already rich in humus I should very likely do so. As recommended in the article, muriate of potash will, in default of wood-ashes, be a good addition to leaf-manure, as it supplies the wanting potash, and very likely is the cheapest form in which that important food can be bought. I believe I have seen somewhere that the chlorine (which with potassium in about equal parts make muriate of potash) contained may be injurious, but I never saw it have that effect when used in small quantities as an addition to other manures.—M. P. ANDERSEN.—*Gardeners' Chronicle.*

KOLA NUTS.—The *Journ. de Pharm. et de Chim.* (October 1884) publishes a series of formulæ of preparations of Kola, by M. Natton, prefaced by the subjoined note on them, by Dr. Dujardin Beaumetz, which was read before the Société de Therapeutique on May 28, 1884. Dr. Dujardin says kola nuts are produced by the *Sterculia kola*, a tree of Central Africa. There the kola is the remedy for all diseases, and is almost worshipped by the natives. It is sold at high prices, and no important bargain is ever concluded without a gift of kola. The natives have found this fruit to possess tonic, nutritive, stimulating, and aphrodisiac properties. They use an infusion of the roasted nut as well as the nut in its natural state. Analysis shows that kola contains a large proportion of caffeine with a little theobromine and tannin. Its use is, therefore, indicated in the chronic diarrhœa of hot countries, where it has been successfully employed by naval surgeons in stomach complaints and in cachexia. Dr. Dujardin Beaumetz himself has found it useful in chronic diarrhœa and in cardiac affections. He gives 15 grammes (about ½ oz.) in the course of the day in two cups of infusion of the roasted kola, or as an elixir, or as a chocolate. M. Natton's formulæ are applicable either to the natural or the roasted kola. A tincture is made by macerating for fifteen days 1 part of kola in 5 parts of alcohol 60°; a wine by macerating for fifteen days 100 grammes in a litre; an extract by percolating 100 grammes with alcohol 60° and concentrating the percolate to the proper consistence; a syrup is made similarly, but instead of concentrating the percolate is made with sugar to weigh 1 kilogramme. Pills are made from the extract, 10 centigrammes in each with some powdered kola, an alcoholate by macerating 1 part of fresh scraped kola in 5 parts of alcohol 80° for fifteen days; an elixir by mixing together equal parts of the alcoholate and of simple syrup; a saccharate, by rubbing together 1 part of fresh kola with 2 parts of sugar sifting and drying; lozenges from the saccharate with 1 part of tragacanth and 6 parts of water to 100 parts of saccharate with any desired flavour; a chocolate with 60 grammes of the saccharate, 40 gramme of cocoa powder, and ½ gramme of cinnamon. Lastly M. Natton gives the following form for a pleasant mixture of kola:—

Alcoholate or tincture...	5 to 20 grammes
Tincture of cinnamon...	1 ,,
Brandy	q. v.
Syrup of orange	30 grammes
Distilled water ... ,,, ,,, ,,, ,,,	150 ,,

TROPICAL AFRICAN MOUNTAIN FLORA.

A very interesting collection of plants has been brought to Kew by that intrepid African explorer Mr. Joseph Thomson, made during his late journey into the Masai country. They have been examined by Prof. Oliver, and consist of about thirty-five species from Kilimanjaro at 9,000 to 10,000 feet of elevation; a few from a crater near Lake Nairasha at 7,000 to 8,000 feet elevation; thirty-four from the Kapte plateau at 5,000 to 6,000 feet; and fifty-eight from Lykipia at 6,000 to 8,000 feet.

These collections exhibit the mingling of North Temperate types with others characteristic of Southern Africa, for which previous discoveries had prepared us. Of these the most interesting are, as new to Tropical Africa, an Anemone, a Delphinium (very different from the Abyssinian *D. dasycaulon*), and a Cerastium of remarkable habit. Of South African forms the most striking is the handsome arborescent Rutaceous plant, *Calodendron capense*, the "wild chestnut" of Natal, to the north of which it had not previously been found. Of northern forms is a Juniper, another genus unknown to Tropical Africa, and which was found forming groves at an elevation of 6,000 to 8,000 feet, and itself attaining a height of 100 feet! it is the *J. procera* of Abyssinia. A *Podocarpus* gathered along with the Juniper, and also attaining 100 feet in height, is probably the *P. elongata* of Abyssinia, which, or a near ally, also occurs in South Africa. The only other Conifer previously found in the equatorial regions of Africa is the *Podocarpus Mannii* from the peak of St. Thomas in the Gulf of Guinea.—J. D. HOOKER.—*Nature.*

THE RUBBER TRADE OF THE UNITED KINGDOM AS SHOWN BY OFFICIAL STATISTICS FOR 1883.

During the five years ending with 1883 the total value of the rubber imports and exports (taken together) has steadily augmented. While it was computed at £3,923,175 in 1879, it reached £6,899,548 in 1883. On the whole, this increase may be regarded as satisfactory, though the exports, as we shall presently show, have not been all that could be desired.

In the returns for 1883, the figures representing the importation of "caoutchouc" (in its raw state) claim especial attention, and for two reasons. In the first place, they show a considerable increase over those for previous years; in 1879 only 150,601 cwt. of caoutchouc, valued at £1,626,290, were imported; while in 1883 the quantity was 229,101 cwt., valued at £3,652,817. The advance is still more apparent when the totals of 1882, viz., 181,726 cwt., valued at £2,754,692, are taken into account. A second feature in the return for last year is the addition to the list of countries from which rubber has been imported of several States which had not hitherto been specially named, their identity having been lost by their inclusion under the vague and general headings of "Other Countries," "West Coast of Africa (Foreign)," &c.

The returns indicating the importation of "manufactures of caoutchouc" into the United Kingdom are full of meaning and significance. As in previous years, Germany continues to pour her rubber goods into this country in rapidly-increasing quantities, the imports from that country having risen from 747,608 lb., valued at £72,716, in 1882, to 1,310,517 lb., valued at £125,483, in 1883. The total amount of the importation of manufactures of caoutchouc into the United Kingdom last year was 2,073,374 lb., valued at £211,408, as against 798,772 lb., valued at £87,591, in 1879.

Compared with 1882, there is a decrease in the importation of guttapercha, the amount in 1883 being 63,800 cwt., valued at £476,881; in the first-named year it was computed at 72,936 cwt., valued at £539,814. Imports of "manufactures of Guttapercha" from all countries have slightly increased—from 197 cwt., valued at £1,825, in 1882, to 375 cwt., valued at £3,331, in 1883.—*Indiarubber and Guttapercha Journal.*

DISEASES OF FIELD AND GARDEN CROPS.

BY WORTHINGTON G. SMITH, F.L.S.

The author has not seen his way to accepting the proofs of so well-established a fact as the heteroecism of the *Uredineæ*. Mr. Smith devotes a chapter to the consideration of the subject, in which he attempts to combat the irrefragable evidence of the truth of this fact furnished us by experiment. Such objections, to give but one example, as that to the different periods occupied by the cultivation-experiments of different observers are not only of no account, but Mr. Smith must surely know from his own experience that the germination and further growth of spores as well as seeds vary exceedingly in different circumstances even under the same observer's hands. But it would be beyond the scope of this review were I to enter upon any defence of the existence of heteroecism in the Uredineæ. What is more particularly to be noticed in this section of the book is a theory of the hereditary nature of parasitic diseases. At p. 197 the author says:—

"We have shown that plants invaded by *Puccinia* and *Æcidium* carry an hereditary disease by which they are saturated, and that the disease is capable of reaching the seeds and reappearing in the youngest seedlings. Now, if plants thus suffering from hereditary disease, and having the latent germs of disease in every part of their organisation, are experimented upon in an unnatural way, have spores of fungi placed near their organs of transpiration, whose germ-threads can pierce the epidermis or enter and choke the stomata and so reach their intercellular spaces, is it not likely that this inoculating process may start into activity the latent germs of disease?"

This is illustrated by the "instance of a person constitutionally subject to phthisis (consumption): give that person a cold and phthisis appears; but the same cold will give rise to rheumatic fever with a second constitution, and scrofula with a third, according to the tendency of the individuals to these disorders." Since Mr. Smith considers the heteroecism of the *Uredineæ* as not proven in spite of the nature and the amount of the evidence, one cannot help being profoundly astonished at the ease with which he, even their own author, accepts such startling speculations concerning the hereditary nature of the parasitic diseases of plants.

In the matter of the potato disease, Mr. Smith gives a history of the whole subject, and a full description of the oospores, which he claims to be those of the *Phytophthora*. At p. 340 there is a sentence of some interest in view of the above mentioned theory.

"It is quite possible, then, that just as every atom of a mycelial thread of this fungus (potato fungus) will continue its growth to a perfect form, so every atom of a brokenup flagellum—perfectly invisible to the eyes even when the highest powers of the microscope are used—may be capable of carrying the poison and at length reproducing the perfect form of the fungus in the potato plant."

Everything is possible, but some things are undoubtedly highly importable, and chief among these are those which we have not the slighest grounds for supposing probable Such is the case with this speculation since (to take the flagellum only) in the first place it is not by any means certain, as the author indeed points out in the same paragraph, that a flagellum breaks up at all, and in the second it is quite unwarrantable on any known basis of fact to suppose that its fragments are endowed with any reproductive function.—GEORGE MURRAY.—*Nature.*

RUBBER NOTES FROM THE REPORTS OF BRITISH AND AMERICAN CONSULS.

BRAZIL.—*Para and Amazon.*—In a remarkably exhaustive report on the commerce and industries of Brazil by the United States Consul-General at Rio de Janeiro (Mr. Andrews), for the year ending June 30th, 1882, there is an interesting account of the extraordinary growth of the rubber industry. This, the report states, is the principal resource of the two great provinces of the Amazon Valley, Para and Amazon, and its product occupies the third place in the national exports. Notwithstanding that this is the case, it would appear that little care is taken with a view to the rubber production being maintained as it might be by the adoption of some effective means of

preserving the tree. According to the report under review, "the rubber tree requires a growth of twenty to twenty-five years before it begins to produce; hence little or nothing has been done for its propagation. The milky sap which forms rubber is taken from the wild tree, which grows scattered through the forests of the Amazon and many of its affluents. The industry, being principally in the hands of an uneducated and half-civilised nomad population of Indian mixture, is of a crude character, and is pursued mostly on the national domain. Nothing has been done to improve the system of labour. A wasteful and exhaustive system has been followed for half a century, and the consequence is that millions of Rubber trees have been destroyed and many others abandoned from premature and excessive use. There are instances of groves of trees which, by careful use and by not permitting them to be tapped in the months of August and September, in which months they change their leaves, have been yielding for 30 years, and are still in good producing condition; but the common practice is so wasteful that many well-informed people apprehend that, unless some remedy is applied, this rich resource will, before long, suffer a serious and perhaps fatal decline." While the somewhat gloomy view of the future of Amazonian rubber-production taken by the writer of the preceding lines may be warranted by such indications as are at present apparent, the exports have rapidly increased in volume and value. The American Consul in the report before us, gives some statistics which clearly demonstrate this. From Para and Manaos, the two principal ports in the Amazon Valley, the export during the five years from 1839-1844 was 2,520,000 lb., of the value of $395,000. In the five years 1854-1859, it had increased to 21,500,000 lb., of the value of $4,000,000; and in the five years 1874-1879, to 66,000,000 lb., of the value of $22,000,000; in 1882 the export was about 10,000 tons, of the value of $15,000,000. A very heavy export duty is collected on this article, the imperial duty being 9 per cent on the value, and, in addition, 12 per cent by the province of Amazon and 13 per cent by the province of Para, making 22 per cent on all that is exported from the latter province and 21 per cent on all exported from the former province.

COSTA RICA.—In the report of Mr. Sharp, Her Majesty's Consul at San José, on the trade and commerce of Costa Rica during the year 1883, the export of rubber at the various ports of the Republic is put down as 333,018 lb., valued at $166,509. It is stated that the Government intended to withdraw the permission given to cutters of rubber on the waste lands of the Republic, "owing to the abuse made of them and the damage done to the trees."

ECUADOR.—We are now able to supplement the figures of Indiarubber exportation from Guayaquil for the five years 1878-82—which we gave in our last issue as having been taken from the report of the British Consul at Guayaquil—by those for last year, when 9,961 quintals were exported, as against 9,034 quintals in 1882. The increase is at the rate of about 10 per cent. The price entered was 18s. per quintal; the total value of the exportation reached £89,649.

JAVA.—In some statistical returns attached to a report by Mr. McNeill, Her Britannic Majesty's Acting Consul at Batavia, on the trade and commerce of the island of Java in 1883, we find the following figures relating to the export of Indiarubber:—To Holland, 632 piculs; to "Great Britain and Channel for orders," 557 piculs; to Mediterranean ports, 16 piculs; to Singapore, 12 piculs—total exports, 1,217 piculs. The total amount of exportation in 1882 and 1881 was 765 piculs and 541 piculs respectively.

LIBERIA.—Mr. John H. Smyth, United States Consul at Monrovia, Liberia, makes some interesting observations on the Rubber Tree in this part of Western Africa, in a report dated February 21st, 1883. He states that the Rubber tree and vine are indigenous, although their milky juice has only become an article of export within a comparatively short time. This has been at a very great sacrifice, since it involved the destruction of the tree and the vine. Both seem to be hardy, and if some means of taking the gum without immediate injury to the tree and vine could be hit upon—such, for example, as the boxing and cutting of the bark of trees, which system has been adopted successfully in taking the substance from the pine trees in north Carolina—the cultivation of the Rubber tree and vine would supply the growing demand abroad for their products, and would constitute a valuable return to labour. The Rubber of Liberia, at the time the Consul-General wrote his report, realised from 33½ to 36 cents per pound. At present the collection of Rubber, he says, the bringing of it to market, and its barter, are wholly under the control of the untutored native races. It is to be hoped that civilised Liberians will give their attention to the extension of what could be developed into a most important industry, by adopting the most approved methods of cultivating the tree and vine and of obtaining the glutine substance without destroying the sources of supply.

LOANDA.—Mr Cohen, Her Britannic Majesty's Consul at Loanda (West Coast of Africa), in a report dated March, 1884 states that the caoutchouc or Indiarubber tree grows wild and in abundance throughout the interior; if it were properly or prudently attended to, the produce of rubber would in a very few years be immense; but the natives have in many places re-acted the fable of the goose with the golden egg by destroying the tree in their greed of obtaining a larger supply of liquid, which has almost exterminated the tree in many places. We extract the following figures relating to the export of rubber in 1882 from some statistical tables with which the Consul supplements his report:—To Portugal, 339,354,853 kilos, valued at 227,060,087 reis; to Portuguese Possessions, 6,782 kilos, valued at 4,672,400 reis; to England, 6,195,912 kilos, valued at 3,141,137 reis; to Holland, 2,665 kilos, valued at 1,599,000 reis.—*Indiarubber and Guttapercha Journal.*

THE CULTIVATION OF CLOVES.—The *Equlibirium* says:—"Cultivators of cloves in Grenada would do well to heed the remarks of Messrs. T. Duncan & Son, who, referring in a recent market report to the great difference between the prices of our product and those of the article sent from Penang, recommend that greater attention be paid by the Grenada cultivator to the time of picking and method of curing. Whilst Grenada cloves fetch 4*d.* to 5*d.* in London, Penang bring 1*s.* 4*d.* to 1*s.* 5*d.* Let our planters reflect on it, and set to work in their own interests."—*Colonies and India.*

BANANAS are not thoroughly ripe and luscious until they part readily from the stem. To have to yank and twist to get one from the bunch is proof of immaturity. Several bunches hanging in the house between a cool, airy pantry and a warm, airy living room will afford a family supply. Bananas behave in ripening somewhat as peas do. The Selectmen of banana Islands keep a string of bunches hung by pulleys or cords along the peaks of the thatched roofs of their bamboo houses. They lower down bunch after bunch in selecting perfect fruit for a guest. —*Straits Times.*

THE INTERNATIONAL CONGRESS convened to deliberate upon the best means of preventing the spread of *Phylloxera vastatrix* was opened on Monday at Turin. Among the personages present were the Duke d'Aosta, Signor Grimaldi, Minister of Commerce, the Syndic of Turin, and the French, Greek, Spanish, Portuguese, Servian, and Roumanian Delegates to the Congress. After a short address of welcome from the Syndic of Turin, Signor Grimaldi explained the object of the Congress, and dwelt particularly upon the necessity of common legislative measures being adopted in all infected countries in such a form as not to interfere with the liberty of trade. It was, however, most requisite to raise barriers to the spread of the Phylloxera.—*Nature.*

THE DWARF TREES of China are very curious examples of what may be done to change the habits of species. The tap-roots and any others which show a tendency to strike downward are kept cut back, and after a long treatment by this method, healthy, symmeterical oaks, chestnuts, pines and cedars are produced which, when fifty years old, are not a foot high, and are kept in pots as any other house-plant would be. The Southern bald cypress is a remarkable tree. It is not evergreen, although a conifer, and does not show any signs of vitality till other trees are well started in leafing out. It is said to be hardy at the North. It reaches a great age and size, a section of one at the Cambridge Botanical Gardens showing an age of 545 years. At Oaxaca, Mexico, there is one which, while 118 feet girth—almost 40 feet in diameter, is only 130 feet high.—*Straits Times.*

Correspondence.

To the Editor of the "Ceylon Observer."

PAPER ROOFING IN INDIA AND CEYLON.

Fyzabad, Oudh, 28th Dec. 1884.

DEAR SIR,—In the November number of the *Tropical Agriculturist*, Note 407, I see a note of the "Willesden Waterproof Paper Company." I have searched the Royal Atlas and can't find out the place. Is it in England or elsewhere? I find *Wilsden* in England.

Above all countries in the world, India is the most in need of a paper roof. I could now use hundreds of thousands of feet of it, *i. e*, if it proved to be cheap and lasting. Could you kindly get me a priced schedule of it and a specification of how it is laid on roofs, or publish the information in your future numbers. With apologies for the trouble, I remain, yours faithfully,

A. CONNELL LICUTT,
Municipal Engineer.

[We leave our enterprizing fellow-citizens, Messrs. J. Walker & Co., to answer the above enquiry, as they have taken a special interest in the new Paper Roofing. Indian correspondents must note that they should superscribe their letters "By Dâk or B. I. steamer" if they wish them to travel for two annas postage: several letters, the above included, have come to us of late by P. & O. steamers, and we have had to pay four annas or 24 cents, double the difference, on each. We do not think the Post Office though, should send such letters save by the route for which postage has been paid.—Messrs. Walker & Co., we are glad since to learn, have sent full particulars to Mr. Licutt.—ED.]

TEA AND RAINFALL IN THE BADULLA DISTRICT: SPLENDID LEAVES.

Dotlands Estate, Badulla, 10th Jan. 1885.

DEAR SIR,—Enclosed please find rainfall for the past twelve months, in which, you will see, there has been rain in each month, but, unfortunately, in the months of April and May (when a good fall is expected) we were much disappointed, and the usual dry months following have been the cause of our coffee being of such an inferior bean. I don't remember seeing autumn crop turning out so badly, although a larger percentage of light and deformed beans is usual after drought. The severe rains last month on the 8th and 12th caused the cherry to ripen up quicker than was expected. On the 11th, the cherry was in fine condition, and I looked forward the following day for a two-bushel picking, but during the night the rain ceased, and a dry north-west wind set in: by morning the cherry was withered, and one side dry on the trees; instead of a 2-bushel picking, it was as much as a cooly could get her 1 to 1¼. Pulping it was out of the question at the time, and it was put into the cisterns, kept damp, and pulped two days afterwards. I wish I could say leaf-disease was on the wane. With me, it has appeared again, and by what I heard in Badulla last week it was *general*.

I enclose you a few tea-leaves from bushes 9 months old to 10, the average being 4 feet, and many 5½, with 4 and 5 primary branches. The few trees I have round the bungalow have flushed 8 times the past year, although the weather was so dry, and I feel sanguine it will do well and pay if we get the railway to Haputale, and, better, if it ever reaches Badulla.—I am, dear sir, yours faithfully,

T. J. E. JOHNSON.

Months 1884.	Days.	Rainfall	Average for 8 years.	Remarks.
Jan.	19	6·26	10·83	Dec. 8th.—There was heavy rain: fall 4·01, out of which 2·96 fell in 1½ hour.
Feb.	5	0·92	3·40	
March	8	2·70	4·95	
April	9	5·40	7·24	
May	8	4·96	4·90	Dec. 12th.—Gauged 4·96—bottle overflowed during the night. With this storm the wind at times was very severe varying from N. E. to N. W.
June	4	1·48	1·56	
July	4	1·00	2·20	
Aug.	7	3·48	4·45	
Sept.	6	1·17	4·15	Dec. 13th.—Strong dry wind from N. E.
Oct.	18	10·23	6·83	
Nov.	17	8·80	8·82	
Dec.	23	17·92	11·94	
	128	64·32	71·27	

[The leaves are large enough to stand the test of "indigeneus," covering the palm of one's hand: we refer to these figures, and to returns from Matale and Haputale elsewhere.—ED.]

TEA IN OLD COFFEE AND GRASS LAND: DOES IT REQUIRE AS CAREFUL WEEDING AS COFFEE?

17th January 1885.

DEAR SIR,—It is amusing to read some of the opinions expressed regarding the treatment of tea planted in old coffee land, but I think the richest we have had for some time is that put forward by "Old Hand" on page 603, where he states that tea seedlings grown in weeds and grass 2 ft. deep (perhaps he should have added with a basket of manure to each plant) are healthier and better grown than plants put in ground always kept clean. Can "Old Hand" really believe what he has written? or is he making game of us new hands? If the former, I would advise him to examine the remaining plants in the clean land or get behind a tree or rock and watch his weeders for half-an-hour or so, when he will, I bet a dollar, discover the reason for the failures and the beggarly appearance of his plants. Will anyone be insane enough to adopt his suggestion to plant abandoned coffee land, and, as he puts it, go to sleep or take a trip home for four or five years leaving the estate to take care of itself, and on his return find himself the possessor of a paying tea estate?

But seriously, Mr. Editor, we have seen weeds and coffee tried with the result that coffee collapsed in six or eight months. Cinchona has failed to grow where weeds were left and even grass fields ceased to grow grass when not regularly weeded. Are we then to give tea a similar trial, expecting it to succeed when utter ruin has attended the attempt in every case?

Had we the flat land, rich soil and fine climate of Assam or the Terai, "Old Hand"'s ideas might to a certain extent be carried out, but to lease land with good soil to grow up untouched for five years would mean—well! it would mean a supply of timber more than sufficient to dry all the tea that land would produce for other five years. S.

A FORAGE PLANT.—The eastern districts of the Cape are indebted to Mr. J. B. Hellier, who brought with him from Cape Town a plant of a recently-introduced cactus from Mauritius, which is like the ordinary prickly pear in appearance, except for the important difference that it has not a single thorn or hair upon it. It is used in Mauritius as a forage plant, and it is expected that it will prove a most valuable boon to colonial farmers, as furnishing feed for their stock in the dry season without the hindrance of damaging the mouths of the cattle as the prickly pear does.—*Colonies and India.*

SMALL BREAKS OF INDIAN TEA.—In future the non-sampling breaks, by which is understood all breaks under eight chests or half chests and 20 boxes, shall be passed over at the time of sale and disposed of at the close of the day. Large buyers can now attend the sales whilst large lots only are being sold, and retire when they are finished, leaving the small lots to those who want them. We confess we have partly expected that something of this sort would come to pass. Indeed, it is a wonder that the old system has endured so long. The increase in the Indian tea trade of late years, has rendered the change imperative, and we have to congratulate the parties interested on the peaceable manner in which it has been brought about. We are not sure to whom the credit is due of having taken the initiative in this very laudable enterprise, but as the meeting was held at the offices of Messrs. William James and Henry Thompson, we think it is not hard to guess from what quarter the influence has come.

THE DUTCH EAST INDIES.—We have received a copy of an Amsterdam prospectus, setting forth an ingenious scheme, whereby the Dutch are endeavouring to overcome the difficulties caused by the virtual stoppage of the Netherlands Indian Trading Bank. It consists in the formation of a new Company, to be called the Netherlands Indian Agricultural Company, with a share capital of 9,000,000 florins. This will not be real capital, but "agricultural enterprises" of the Trading Bank, representing an outlay of 12,800,000 florins, will be taken over by the new Company at a valuation representing the lesser sum, and this will be called "capital." Then the new Company is to try to obtain real cash as working capital by means of an issue of five per cent Debentures, also to the extent of 9,000,000 florins. In order to make these Debentures attractive, those who subscribe them would appoint the Board of Directors and manage the properties. They are, in short, to be mortgagees in possession. We should imagine that nobody here would enter into such a delicate and unpromising piece of financing; but if the Dutch can find the money themselves, they will have done well. The scheme, however, has rather a desperate look about it. Strangers are asked to find the money to carry on a business which can offer no other security than a multitude of unrealisable assets which have landed the original owner in ruinous losses, and all for the sake of keeping that owner from declared bankruptcy.—*Planters' Gazette.*

BRITISH COLUMBIA.—Here is an encouragement for those who wish to follow Mr. Pineo's example:—

Where should the Anglo-Indian go to settle when he retires? Let him go to British Columbia, writes Selim, in the *Times of India*, a country so blessed by nature that, in the glowing language of the *Spectator*, it is a place "where game is so plentiful that you may see fifteen deer hanging in a butcher's shop at one time; where fruit is so plentiful, that the natives live on little else; fish so fine that Columbia salmon have acquired a reputation in Europe; where iron and coal and the nobler metals abound, and gold is found in every stream; where the scenery vies in boldness and grandeur with that of Switzerland and the Tyrol; where the coast, washed by the grandest and most tranquil of oceans, is indented with fiords like the coast of Norway—a land blessed with a climate so salubrious that valetudinarians go thither in search of health, and so mild and fresh, that grass grows all the year round. Clearly this earthly paradise is one of the countries of the future." Very much so, indeed. And with exchange going down to nothing, and prices going steadily up, and school bills for Tom, Dick, and Harry coming in with that regularity which *Pater Familias* finds a trifle monstrous, the best thing we can all do is to pack up our traps and take ourselves off to this earthly paradise. A country where the streams are full of gold and salmon, and where venison is more plentiful than mutton, would be an agreeable change after India.—*Indian Agriculturist.*

TEA FLUSHES.—What the ultimate returns from tea may be, is, of course, a question open to debate, but we hear at present of superintendents being driven almost to despair by their inability with the appliances at their disposal, to overtake the luxuriant flush which the tea trees have put on. Hand rollers are in great demand.

BRAZIL COFFEE CROPS.—The *Gazeta*, of Piracicaba São Paulo, is of the opinion that next year's coffee crops will perhaps be the smallest of the last ten years, for the reasons, (1st) that the last crop was large and the trees are exhausted; (2nd) that the seasons of the current year have been very irregular, there having been many dry months where there should have been rainy ones; (3rd) that great injuries have been sustained from frost. The blossoming, our contemporary adds, is not showing up very well. It is useless, perhaps, to call the *Gazeta*'s attention to the remarkable similarity between this prediction and all those which have gone before. When we find a provincial paper, or a coffee planter admitting the probability of a good crop, we shall feel like publishing his portrait.—*Rio News.*

THE COCONUT OIL TRADE OF THE MADRAS PRESIDENCY.—In reviewing the coastwise trade of India for 1884-85, Mr. O'Conor states:—Oils, mineral: petroleum is imported into Bengal from Burma where it is produced, but the whole quantity exported from Burma is still small, only 429,037 gallons last year. Castor oil is imported chiefly into Bombay from Madras ports and those of the Gaekwar's territory. Burma and Bengal also receive some from Madras. Total value of trade 8½ lakhs, representing a quantity of 704,574 gallons. The trade in cocoanut oil is much larger: 1,819,684 gallons, value 25 lakhs last year. This is mainly a Madras industry, a large proportion of the oil being sent to Bombay from Madras ports and Cochin, the rest being sent chiefly to Bengal and Burma. Earthnut oil is also a Madras industry. It is sent thence and from Pondicherry chiefly to Burma and in smaller quantity to Bengal.

ARTIFICIAL FRUIT FLAVOURINGS.—Among the "people I have met" during the Christmas holidays, passed among a large circle in a country house, has been the distinguished chemist to whose researches we owe the discovery of the artificial flavourings now substituted for the juices of natural fruits. In conversation with him he has given me the history of his curious discoveries. One day a Frenchman brought him a small phial containing an essence which he had accidentally found, which smelt strongly of jargonel pears. My friend carefully analyzed this, and found the base to consist of the fusel oil which it is the aim of all spirit manufacturers to eliminate from their whiskeys and other similar products. His researches also led him to determine that what gave the flavour and smell of the jargonel pear was what is known to chemists as 'valerian.' He argued, that, if fusel oil could be thus made to absorb and again yield one flavoring, other substances might be made by their addition to yield a variety of them. It would take too long to narrate here all that was told to me of further experimenting. Suffice it to say that all kinds of substances—among them being rotten cheese—were tried, with the result that ere long every description almost of fruit-flavoring was produced, and what was at the time sold at twenty guineas the ounce was made by my friend at the cost of a few shillings. He named his discovery to his friend Professor Abel, by whom the facts were again named to other chemists as a curiosity, and the manufacture soon became common; but, prior to their becoming so, and while the secret remained in for discoverer's hands, he was clearing, he told me, them £80 to £90 a day.—*London Cor.*

THE ACREAGE OF BEARING TEA ON ABBOTSFORD ESTATE, CEYLON, 5,000 FEET ABOVE SEA LEVEL.

A Ceylon correspondent of the *Indian Tea Gazette*, has insinuated that the produce of a number of fine trees scattered over the plantation went to swell the returns from the acreage shown as bearing. The several thousands of seed-bearers scattered over Abbotsford were, of course, referred to, and we can only repeat that not a leaf from any of these went into the returns of 1884, recently published. But there are pruned trees along paths and drains, which were plucked. They were, however, estimated for acreage, the space they cover having been over rather than under estimated for extent. The figures for the acreage of seven to eight years old tea, which produced 506½ lb. average per acre in 1884, are thus made up, as has frequently been stated :—

Cattle-shed field	15	acres.
Bungalow ,, ...	5	,,
7-years old ,, ...	70	,,
	90	,,
Add bushes along roads and drains, a liberal estimate	20	,,
Total... ...	110	acres,

to which total the returns referred.

We may add that the late Mr. Cameron advised the plucking of the seed-bearers, but this advice was set aside, Mr. Chisholm Fraser having stated, what proved to be correct, that flush from such trees gave weak tea. Before 1884, therefore, the plucking of the big unpruned trees kept for seed was deliberately discontinued.

We may add that some of the trees left for seed-bearing (superior hybrid Assam jât) have neither blossomed nor fruited at the high altitude, though from eight to ten years old. The late high wind, some readers will be sorry to hear, proved fatal to the giant tea tree (88 feet circumference) before the few first blossoms it began to show had passed into fruit.

COKE AS FUEL FOR TEA MACHINERY.

In Nov. 1883, Mr. Monk, of the Colombo Gas Works, enabled us to answer a query from Maskeliya about the use of coke as fuel for tea driers. After showing that English foundry coke was unsuitable, apart from the price, R50 to R55 per ton, Mr. Monk stated the terms on which local gas coke could be supplied. In reply to a note about coke for a household stove, Mr. Monk wrote a few days ago, giving details which may be interesting and useful to our tea planting readers :—

"If the coke is required for tea-drying machines we will send a four-ton *trial* lot for R18·75 per ton delivered at station or wharf here, *cash*; or R20·75 per ton cash within six months. Bags are lent free of charge for a fortnight; if not returned free of all charges within 16 days, 60 cents each charged for them, 30 to 33 per ton.

"Mr. Horsfall, 17, Hospital Street, is trying coke with one of the American Evaporators (Davies's) drying cardamoms just now, but how he is succeeding I don't know, as he may not have had trial long enough yet to give an opinion. There must be considerable advantage with coke for tea drying machines: no smoke, and, if any, fair draught: any heat can be obtained, and, as it is all pure fuel, no waste un il burnt to fine dust small enough to pass through a tea sieve—none other should be thrown away, as the ashes will all burn, either to keep down heat when too strong by damping fire a little, or by opening damper a little more to give draught enough to burn the ashes. The coke should be broken to pieces, not larger than an ordinary size orange: sometimes pieces of coke are very much larger."

"*P.S.*—I may add, no probablity of price of coke advancing over R20 per ton nett here unless coal increases in price which is not probable for some time.

"As all drying machines are regulated in temperature under sight of a thermometer, I presume much economy of fuel may be effected by a careful person in charge having damper open only sufficient to get desired temperature: if damper open too much, much of heat merely passing away by the chimney."

In his letter of Nov. 1883, Mr. Monk stated :—

"The carriage to Nawalapitiya is R14·70 for one ton, R29·40 for two tons or any quantity up to four tons for the R29·40, so that it is much cheaper to get a four ton lot; a special quotation would be given for latter for a trial. The Gas-Works coke is best for stoves, only requiring a wood kindling and fair draught, and broken small for use."

At R29·40 for four tons to Nawalapitiya, the rate per ton for railway carriage would be R7·35 to Nawalapitiya, and in proportion for greater distances, we suppose. The distance from Colombo to Nawalapitiya is 87 miles, while the distance thence to Nanuoya will not be one half more, only 42 miles or rather under. But say that one half is added to carriage, that would be about R11 per ton from Colombo to Nanuoya. The total cost of a ton at Nanuoya would thus be R29·75, say R30. How does this compare with wood fuel, looking at the superior heating power of the coke and the absence of smoke?

PROGRESS OF PLANTING IN CEYLON.

It is interesting after a considerable interval to mark the evidences of progress along our railway line. The Liberian coffee and cacao seen in the Polgahawela district looked healthy and vigorous; the Kadugannawa plantations showed an encouraging covering with the same new products intermixed with the grass fields wisely grown where waah had done its worst. Mariawatte, Sinnapitiya and several other tea clearings in the Gampola neighbourhood looked refreshingly green; while with Ambagamuwa commenced a wider field of tea operations in numerous clearings young and old with shrubby plants of the type becoming so familiar everywhere in our planting districts. A companion who has had experience higher up, declared the growth to be less satisfactory at this medium elevation than on good soil at 6,000 feet and upwards. But not only good soil, but shelter and an easterly exposure, must be conditions of success in the latter case. A glimpse of the great Kadawella tea-house in the middle of the wide-extending "gardens" is caught from the train before entering in the long extending Watawala valley through fields of coffee which, with lines and groves of cinchona at intervals, look as healthy and vigorous, although not so rich in crop, as ten years ago. A picture of desolation—weeds and walking-sticks—in approaching Hatton is succeeded, after passing through the long tunnel, by a stretch of country where coffee to the ordinary glance gives not the slightest indication of a decaying industry. Surely Dimbula never looked better in its coffee and cinchona groves apart from the promise of tea, at this season of the year, even in the days when leaf-disease had not interfered with the crops of from 4 to 6 cwt. per acre.

But what a splendid series of tea gardens were lost (for some dozen or fifteen years) when the Kotagaloya valley was cleared for the production of fragrant berries rather than the fragrant leaf. Surely all the conditions required by the tea planter are found between Poolbank and Craigie Lea—the perfection of

lay of land especially, in easy rolling mounds and sheltered valleys, plenty of sunshine and moisture and very decent soil for tea. And yet it must be very hard on proprietors to sacrifice the growth of years in vigorous looking coffee.

Not till we had passed through Humphreys'* Gap,—did we see such groves of cinchona as would warrant the expectation of heavy harvesting and exports to equal those of last season. I agree with Mr. Talbot, that to the passing traveller at least there is not much evidence of tea planting: the covering of coffee seems to leave no room for anything else: but no doubt many fields are to the proprietor more valuable for the young plants now rising under shelter than for the showy bushes shortly to be sacrificed. Higher up in the valley of the Dimbuldanda, we heard of pluckings of tea which indicate heavy flushes and all the rush associated with crop time; while in the neighbourhood of Nuwara Eliya bark is being harvested at the rate of half a ton a day. As for Nuwara Eliya itself, the place is surely at its best on such a day as this:—a cloudless sky, bright sun, and pleasant breeze; all nature refreshed by recent rains which again have filled Gregory Lake to add beauty and contrast to the everlasting hills with their diversified verdure. Autumn tints there are in abundance; the air at times is redolent with the scent of violets; the gorse is in full bloom; beds of geraniums and roses vie with fuchsias and petunias in nearly every cottage garden, and here indeed while you are being scorched or melted in Colombo we have a bit of Europe smiling in tropical Asia.

CEYLON UPCOUNTRY · PLANTING REPORT.

THE ROMAN-DUTCH LAW AND LOCAL INVENTORS—THE SIROCCO TEA DRIER—THE AMERICAN EVAPORATOR FOR CACAO—CEYLON AS A PRODUCER OF TEA MACHINERY—COFFEE GIVING PLACE TO TEA—COFFEE A RARITY.

19th Jan. 1885.

I was hearing that the Roman-Dutch law, that labyrinth amidst whose mazes the soul of Judge Berwick has for many years wandered, deals very kindly with all local inventors. It is said to come in handy regarding a tea roller of native manufacture, which was threatened with having to give an account of itself for injuring the patent rights of another. Anything like restriction of trade has always been viewed by the jurist with a jealous eye, and the Roman-Dutch law-givers have, it is said, that eye very wide open indeed. This is just as it should be, for what the colony wants is not that one man should have a monopoly say of a particular motion of a machine but that the best machines should come to the front, and that there should be a fair field and no favour. Of course the inventive genius of a man ought to be rewarded and his machine protected if he has deemed it worthy of a patent, but not in such a way as to throttle the invention of others.

Talking of tea machinery reminds me that Barnagalla has erected a No. 3 Sirocco, and that it is giving complete satisfaction. It is questionable if tea can get burnt in this machine; anyhow it has the merit of turning out a regular sample, is easily worked and quickly learned.

The American Evaporator is proving a success regarding cacao, and may yet become a very common machine on estates whose acreage of this new product will not allow of anything more expensive. It would not take very long to pay itself in a wet season, if there be such a difference in price as I was hearing of between bad and good cured nibs. Cacao which had to be washed in wet weather, and which could not be dried for want of heat, brought R15 a cwt. as against R42 of that which had the weather in its favour.

I hear of several people who are dabbling in new tea driers, but with what success I have not learnt. If the thing is to be done—that of getting A1. tea machinery—depend upon it Ceylon will be well to the front ere long. We don't take much pride in the inventions of other folks; and as Ceylon coffee machinery has always held the first rank in coffee-producing countries, I have no fear but that the traditions of the past will be handed on, and that in tea driers, rollers, sifters and such like, the Ceylon make will not take a second place.

On old coffee estates, the trees in many places are being knocked down to give place for tea. Ere long the Old King will be a curiosity, where formerly be held such an extensive sway. Why, I was hearing of a planter who had the mana grass in his estate set on fire, which fire ran into a little coffee and burnt it. A claim was made for damages on the ground that coffee was becoming such a rarity now that it had to be carefully conserved, and could not now be burnt with impunity! Well it is that coffee preceded tea, for as one said to me there was a kind of providence in it: tea is willing to grow where coffee won't, but, if it had been the tea which had failed, it is very questionable indeed if coffee would have succeeded so well as a second fiddle.

PEPPER CORN.

* Humphreys': it is on Ritnagerrie estate.—ED.

TROPICAL AGRICULTURE IN NORTHERN AUSTRALIA.

The colony misnamed South Australia possesses, equally with the neighbouring colony of Queensland, a northern territory which is tropical in climate. But the policy of the two countries has curiously diverged. Both began by offering premia on experiments with tropical produce, and South Australia consistently followed up this offer by arranging with the Indian Government for the introduction of Indian cooly labour, Major Fergusson being despatched on a mission to India to arrange the matter. A bill for the same purpose passed the Queensland Legislature, but under the influence of a white working-man's ministry and parliament, the law has recently been repealed. This was done just as the suepply of South Sea labour began to fail, and the grat sugar industry which gave remunerative employment to large numbers of whites is now threatened with utter ruin. This, after five millions of capital had been embarked in the enterprize, with an annual expenditure of £500,000. Northern Queensland possessing conditions far more favorable to tropical cultivation than the northern territory of South Australia, is thus placed in a most disadvantageous position, and no one can wonder that there is a cry for separation. All tropical Australia, in truth, ought to be governed by Lieut.-Governors or Superintendents and largely on Crown colony principles. Although it is legal to introduce Indian coolies to South Australia, few or none have actually been introduced, and our readers will see that the experiment of coffee, cacao and cinchona culture, initiated by Mr. H. Poett, formerly a planter in Ceylon (assisted by Mr. Farquhar Mackinnon, also a *cidevant* Ceylon planter), is apparently to meet the fate of the sugar-growing experiment on De Lissa plantation. To sugarcane there, we heard the "white-ants" (termites) were terrible enemies. The sugar land seems to have been, in any case, badly selected. There is no such statement regarding Mr. Poett's "Rum Jungle," but the Adelaide shareholders

have got frightened at the estimates of expenditure. On the Esmeralda plantation in the same territory, it will be seen that tea plants are flourishing. We suspect the two great difficulties in the Northern Territory are want of steady, well-distributed rainfall and the absence of a plentiful and cheap labour supply. The more we learn of competing countries, the more favored the case of Ceylon seems to be in regard to climate, means of communication and labour supply.

In my last letter I gave a rough report of Mr. Poett's coffee plantation at Rum Jungle. I visited the estate two months ago, and was pleased to find fifteen acres cleared and planted, near the nursery, with coffee, cinchona, and india-rubber, which were growing well, except the last named, as it was suffering from dry weather. The coffee and cinchona show plenty of wood, considering the dry weather since they were planted—last December. A six-months' drought is very discouraging. The plants doing well in the nursery are the diro-diro, dates, arecanuts, oranges, pumaloes, jak-fruit, mangoes etc. Plantation operations are almost suspended just now, consequent upon the want of success connected with the De Lissaville sugar plantation, [Mr. De Lissa told us personally last month that he is not wholly to blame for selecting the land. It was *shameful selection* whoever did it.—Ed. *T. P.*] The Adelaide shareholders of Poett's Company are rather afraid of results; or at least, until some tangible hope is shown. Adelaide capitalists are now cautious in launching out money to carry on the coffee estate, which is a serious blow to the manager, Mr. Poett, who has done his share of work with energy and success. The incautious policy of the directors in suddenly stopping supplies at a time when thousands of fine healthy coffee and cinchona plants are ready for transplanting has caused Mr. Poett to meet the local creditors; and I learn, with regret, that the property is now for sale. Mr. Poett intends to go South with the view to reorganize the Company and resume planting operations at once. In December last Mr. Stevens, manager for Fisher & Lyons' pastoral properties on the Adelaide River, arranged with Mr. Poett to supply him with coffee and india-rubber plants, and Mr. D. Mackinnon planted them in the roughly prepared ground at the experimental garden on the said river. In 2½ months they thoroughly struck, were well shaded in wet weather, and the land kept free from weeds, etc. From reliable sources I hear that the coffee and india-rubber plants are thriving well. Upon low, flat and cold soil the rubbers have not grown so well, and many of them were destroyed by a small black beetle; but this pest has not interfered with coffee planted on good ground naturally drained. Had the coffee been planted in wet soil it would, no doubt have suffered from "wet feet," so called by coffee planters. Mr. Stevens, however, is delighted with the growth of the plants. The Duke of Manchester visited this plantation in company with the Hon. M. Parsons (Government Resident), Messrs. W. H. Gray, Holtze, and others, all of whom spoke in flattering terms about the promising aspect of the plants. There is a large area of land on the Adelaide River suitable for cinchona, tobacco, and sugar-cane. I will report on this experimental plantation now and then as I expect it will prove a complete success especially after so many mistakes having been made in cane and tropical culture. Mr. Parsons has unlimited faith in cane culture, as the Chinese have made canes grow well; but his statement made two years ago, that the Northern Territory could grow better canes than Queensland, has yet to be proved. It is necessary for me to be candid and give my impression as accurate of the truth. After twelve years' experience in the Territory, my opinion is that all the land from Cape Wessell to the east of Port Darwin and Point Blazes to the west, and a 100 to 200 mile inland, will produce little else but minerals. Stock will thrive only during certain season of the year and oven then a limited quantity must be run upon the land.—D. G.—*Tropical Planter.*

ESMERALDA PLANTATION, MOURILYAN.

(*By Cedric Merton.*)

This future Port Jackson of the North now boasts of a township upon more than paper and property went high the other day at the Government sale. Many large steamers visit the port, and next year the exports will be something worthy of special notice. On the Johnstone the plantations have had a fair crushing, considering the quantity of cane available for the mills. The Innisfail plantation will probably make 500 tons of sugar this season. Mr. Dunal has worked the new French mill very well, despite numerous imperfections in plant. Double crushing on the Mourilyan Sugar Estate has produced from 72 to 75 per cent. But I propose in this letter to write about the "Esmeralda" tropical plantation belonging to Messrs. Seymour and Allen, and ably managed by Mr. Waldegrave J. Thompson. It is situated on the left slope of the bluff hillside after entering the harbour. The scene is grand and picturesque. The magnificent lake harbour, with its mirror-like smoothness and noble ranges of fustet groves and thick foliage hills, are fit themes for a Macullough or other woodland painter. A few months more and it will have lost its primeval grandeur. The American axe and carpenter's skill will denote that Mourilyan Harbour is a place of deep importance. Apart from sugar its exports will be varied. The "Esmeralda" plantation is well situated for tropical culture, and all the various economic plants now growing there are thriving in an astonishing manner. The proprietors are only experimenting with plants as yet, and their operations are much controlled by the state of the labour question, upon which the extension of the cultivation much depends. Such plants as coffee, tea, cocoa, indiarubber and pepper, though in their infancy, look the very picture of health—a sure proof that they have found a congenial soil and climate. An examination of the soil and a few months' residence here are sufficient indications to anyone versed in tropical agriculture. The tea plants now growing are doing exceedingly well. They are known as the "Assam Hybrid" variety; that is a cross between the China and Assam varieties, but its cultivation cannot be recommended without abundance of cheap labour. The two varieties of coffee, cocoa, and indiarubber will, I think, form the chief products of the Esmeralda estate, and if grown on the same acreage a large staff of cheap labour can be kept up and be available for each successive crop. 676 coffee trees, 80 cocoa and 80 indiarubber trees would not be too much for the soils; that is, coffee planted 8 × 8, and cocoa and indiarubber 16 × 16, alternated. This mass of foliage should keep the soil almost in its virgin state if anything like a *pro rata* amount of manure were returned to the soil within a few years. There seems a great want of confidence displayed by capitalists in any industry in the colony but sugar, chiefly owing to the failures in Ceylon and India; but I think the apathy of the planters had almost as much to do with their losses as leaf disease. In turning to the Sydney prices current, coffee is quoted at 8½d per lb. Now it is well-known that you cannot get a pound of roasted coffee fit to drink under 1s 6d per lb. Who gets this 9½d? It does not cost to roast, so it must lay with the whole-sale grocer, while the planter can harely pay expenses. By the following table you may see what could be realized per annum, per acre, if put upon the market direct from the North:—

	£	s.	d.
Coffee, the 3rd year from planting, 3 cwt. per acre, at 1s 6d per lb	18	6	0
Cocoa, the 3rd year from planting, 5 cwt. per acre, at 1s per lb	28	0	0
India-rubber—say 80 lb., 18 months from planting, at 5s.	20	6	0
Total	£66	0	0

These crops are estimated very low, as, with anything like luck, a crop of 1½ cwt. has been picked off two-year-old trees; and wth each of these trees, the older they grow the better they crop. As for instance, one ton per acre was a frequent crop in India seven years ago. The amount of rubber that can be topped from the tree increases by 1 lb. every year, so that the third year's nett proceeds should realize £80 per acre. I like to see this estate so promising, as planters should not put all their eggs in one basket.—*Tropical Planter.*

CINCHONA CULTIVATION IN BOLIVIA.

We have heard from time to time of the establishment of cinchona plantations, to take the place of the extirpated natural plants in Bolivia, on portions of the Andean ranges famous as being the favoured habitat of the fever plants. We now copy from the *Independent Journal* a very interesting account of the experiment of regular cultivation, contributed by the American representative at La Paz. We do not think cinchona growers in the Eastern Hemisphere need feel much more anxiety in regard to the competition of the cultivated bark from Bolivia than they entertain in regard to the natural bark, which at present cannot bear the cost of carriage and the local duty, for, as will be seen, there is an export duty on the "quina bark." The enumeration of so many millions of plants in the various *clearings* we were going to say, but clearings in the proper sense they are not,—the millions of plants sounds large, but, apart from what we know in Ceylon of "insidious defunction," there is the clear indication of the same fatal mistake which Junghuhn made in the first experiments in Java, that of putting the plants out in the natural forest, the undergrowth only being cleared away at intervals. Plants grown under such circumstances shoot up thin and spindly, as may be seen in Java to this day by the sides of the path leading up to the Tankobanprau volcano, and as might be seen at one time at Hakgala, in the case of plants put down in early years according to advice from Java. The plants which Mr. Gibbs speaks of as producing an average of 4 lb. of bark (green bark, no doubt) are probably the trees cut down in the natural forests and not any as yet produced on the so-called plantations? What Mr. Gibbs says about the altitude at which plants are grown, 3,000 to 4,000 feet, is interesting, but some difference of latitude must be taken into account, and certainly experience in the East is contrary to the statement that highgrown cinchonas are deficient in alkaloids. Dr. Trimen's notice of the splendid analysis of highgrown succirubra bark will not be forgotten. The American writer does not enter into details of species cultivated, but what he does say seems to justify the inference that calisayas of vari-coloured foliage are the favoured kinds with the planters in Bolivia. If the prevailing type is Ledgeriana, good and well for the planters; but we now know that *Cinchona Calisaya* includes not only the best tree known for richness of bark but a number of poor or worthless varieties. Amongst the enemies of the cinchona tree, we have never in Ceylon heard of a large black ant, and, even if our canker is unknown on the Andean plantations, the ravages of this insect seem, from the account given, to be a counterpoise. But it is distinctly stated that 25 per cent of the trees planted out *rot off or decay in the first two years*. The soil and climate of Bolivia do not, therefore, seem much more favourable to the growth of *cultivated* cinchonas than those of India and Ceylon. It will be observed that the Bolivian planters adopt the coppicing process solely, neither stripping nor shaving having been tried by them. But, as one of the German superintendents said, the enterprize is as yet in its infancy and the planters have much to learn. India, Ceylon and Java which received the precious trees as gifts from the slopes of the Andes can contribute some valuable information in return, if the Bolivian planters will only avail themselves of our experience. How plenty of sun and wind as well as rain are to reach trees planted amidst the natural forest, that forest being only partially cleared of undergrowth, we cannot see.

CULTIVATION OF CINCHONA IN BOLIVIA.

BY MINISTER GIBBS, OF LA PAZ.

I have devoted some time and attention to acquire data and information relative to the next important article—cinchona bark, or quina—of which large quantities are exported yearly. Formerly it was gathered by the Indians, and in such a manner that large forests were destroyed, trees cut down, the bark taken in any way merely to make up large quantities; today the quina plantations, or, as they are called here, quinales, are cultivated and nourished with care and agricultural science, the principal planters being Germans—one, Mr. Otto Richter, possessing two million plants; the estate of Mr. John Kraft, a Hollander, lately deceased, two million.

The cultivation of quina in plantations, systematically, has been carried on for about seven years, hardly long enough to show all the advantages, as there is room for much study and improvement.

Mapire, about sixty leagues north of this place, or about five days' journey, has under cultivation about four million five hundred thousand plants; Eonga, north-east of this city about twenty leagues, five hundred thousand plants; Yungas, east-north-east twenty leagues, one million plants; Guanay, east of Mapire, five hundred thousand plants; total, six million five hundred thousand plants.

Where the principal quinales are it is a very rough and broken country, the Andes being seamed and cut into deep valleys in every direction. The trees are planted on the sides of the valleys or ridges in altitudes of about 3,000 to 4,000 feet above the sea. They will grow higher up, even to 8,000 feet, but are stunted, and will give little or nothing of what is called here the quina salt. The plants want a great deal of sun, heavy rains and fresh winds.

I have conversed with three of the principal superintendents of the large quina plantations—all Germans—and they say that the cultivation of quina is yet in its infancy, and there will be many improvements through time and experience.

A tree will give from 15 to 20 lb. of seed. The seed is collected in November and December (the early summer months here), and planted very thickly in boxes or beds about 12 feet in length and 3 feet in breadth and placed on a slight decline or fall and well irrigated. When the plants are about 6 inches in height and have a few leaves, from five to six (which is about five months), they are transplanted; holes of some 8 to 10 inches deep are dug about 6 feet apart, in which they are planted. The plant is covered partly over with twigs and other light stuff, grass and leaves, to keep off the sun for about three months. When the plant is strong and healthy, the undergrowth of other plants is cleaned out and great care is taken. This attention continues for about two years, and then the plants that are left are considered sound. About 25 per cent of all the plants decay or rot in this time. Afterwards the undergrowth is cleared out once a year, and when the tree is six years old it is productive, grows to about 14 feet in height, and has a diameter of about 6 inches up to 6 or 7 feet. Where the bark is of the most productive kind, the trunk grows straight and slender, and has the form of an orange tree. When a tree is left standing for ten or twelve years, it is over a foot in diameter, the bark is thicker and heavier, but not so productive in quinia. The bark is ready to cut when the tree is about six years old. An incision is made around the trunk of the tree a few inches from the ground, another incision some 24 inches above around the tree, and then two incisions opposite, lengthwise. The bark is pulled off in two pieces. Two cuts, and sometimes three, are got off each tree, 22 to 24 inches in length, and 7 to 8 inches in width. When removed it curls up like the cinnamon bark. After the tree is stripped it is cut down, leaving a trunk about 12 inches above the ground, and from the base, where the bark has been left, there spring out some fifteen or twenty shoots or sprouts; these are left growing until they are a little higher than the stump, then they are thinned out, leaving two or three; they grow fast and in five years give good bark.

The trees produce on an average about 4½ pounds of bark, and are stripped in the southern hemisphere late in the spring—October to January. The bark is placed in paved

yards, and is generally cured in four days, but if rain sets in, at times it takes nearly three weeks.

The principal enemy in the insect line is a large black ant, which is very destructive. There are various classes of the quina tree, calysaya, green and purple. The greater part of the quina passes through this city baled and sent to Tacna and Mollendo. Cinchona is the common name for all quina.

The market price is now 40 cents. per lb., Bolivian currency. It has sold as high as 200 bolivianos per quintal. It formerly paid a tax of 6·40 bolivianos per quintal; now one-half, 3·20 bolivianos, one-half to the Government, and one-half municipal.

As the greater part of the quina forests were destroyed, and until very lately, the cultivation of quinia has not been carried out in a proper manner, it is only now that it may be said to be a regular business. The highest exportation of late years has been 20,000 quintals: but it has dwindled down for various causes, so that this year it will not be more than 5,000 quintals, and at present prices leaves no profit, the expenses of getting it to the cost being heavy.—*Independent Journal.*

PLANTING IN JAVA.

The land is saved for the present, and it has been satisfactorily proved that all confidence in Indian cultures, even sugar and coffee, is not lost at home. The Neth. Ind. Handlesbank, with a fully paid up capital of 12 millions guilders, had been giving out more than double its capital in loans on plantations, produce, mercantile stock, &c. As long as their drafts were fully trusted, everything went well, but when rumour said that this bank lost a good deal by the failure of Dummler & Co., drafts were presented for payment too sharp, and the Bank vacillating on its natural supports, had to throw out a hint for an extra branch leg, the Neth. Ind. Landboun Co., with a capital of 9 millions; and the beauty is that within twice 24 hours the capital was more than fully subscribed.

The Colonial Bank, with a fully paid up capital of five million guilders, was very much in the same fix, and asked for the loan of another 5 millions. The confidence in this Bank was, it seems, not so unlimited as in its sister bank; at least some trouble was taken to get the required capital together, as people said that it had not been so careful in laying out its capital; but the money did appear. Now you would say Rome is saved, and all Batavia was perfectly astounded, when the Manager and the whole staff of the chief branch of the bank at Batavia got, as a New Year's gift, their leave of absence unlimited. Ra...Ra.. Why is that? Messrs. Dorrepaal & Co., of Samarang, who were as deeply involved in produce as any bank in Java, could not stand any longer the sad conditions under which planting is at present; tried to change their firm into the Dorrepaal Bank of the Verstenlanden with a greatly enlarged capital and succeeded at once; so you see, that the quiet Amsterdam people have still some cash in their safes and what is more worthy of mention is that they are not unwilling to come forward and assist, where assistance is deserved and can be given with any safety. The King subscribed 100 thousand guilders, and Mr. Cremer and Mr. Janssen each half a million. The most wonderful part of the whole is, that new shares were sold the same week at 86 per cent., so, it can only be supposed, that many people have bought shares and sold them again at a loss, just to save themselves from larger losses by the fall of the old bank.

The Netherlands India Railway Co. has also shown its sympathy for the sufferings of the sugar-planters by reducing the freights on sugar on their lines by more than 35 per cent. and although this measure is only temporary, and on condition that the sugar-planters send all their sugar-produce by the lines of this company yet it is highly to be commended, and it is to be hoped that the Neth. Ind. Government will follow this good example and also reduce the very heavy freights on the Government lines.

PLANTING IN MALACCA.

There is very little prospect of a return to prosperity for this place. The price of tapioca has advanced, but not sufficient to induce planters to increase the output of their factories. The plantations that remain open, only worked the roots which would spoil if left on the ground, and stocks of the manufactured article are held here in the hope of a rise in price. Liberian Coffee is being cautiously tried, but very few people care to expend much of their capital on planting of any description, owing to the low price of nearly all kinds of produce.—*Cor., Singapore Free Press.*

WAGES OF LABOUR IN DARJILING, N. INDIA.

There has been a good deal of discussion recently, provoked by the action of a Company in raising the wages paid to Nepaulese coolies from the average of R5-8 per mensem (what we should call R5·50) to R6-8. The rise, which means on many estates an addition of R300 a month to expenditure in labour alone, is denounced as unnecessary, the coolies being quite contented, as well they may be, for in most cases the money wages are supplemented by the produce of pieces of land bearing two crops annually, of grain we suppose. Here is the picture drawn in the *Indian Planters' Gazette* :—

It is a fact well-known by all who have had any reasonably long experience of Napaulese coolies working on tea gardens that as long as they can get enough to eat and drink, they will do no extra work—more especially, if they can borrow from the sirder—and that extra pay to them means so many day's more idleness in the month: or, to put it in other words, a cooly who at the present rate of wage can earn R5-8 a month by 25 to 26 days' work would only do 21 to 23 days if the rate were R6-8. Again that the present rate of wage is amply sufficient for the work done is proved by the fact that on most gardens in the Darjeeling district the labour force available is quite sufficient for present requirements, and that in most cases the old coolies have remained steadily on the gardens where on they had settled down, in spite of the counter attractions, offered them elsewhere in the shape of increased pay. It must also be remembered that within the last few years rice and some of the other food grains have fallen very considerably in price, and that altogether tea coolies are much better off, generally speaking, than they were ten years ago at the same rate of wages in money. It must be remembered that in addition to the actual wages earned by a male cooly, he has a general rule, his wife and two or three children who between them earn on an average another R6 to R8 a month, so that altogether the incomings of an average Nepaulese household on a tea garden are not less than from R12 to R14 a month, and this in addition to a good comfortable house, a patch of land from which at least two crops in the year are raised, firewood and other little odds and ends which put together fully represent almost as much as the amount actually earned in coin by the family. It is no wonder therefore that the tea coolie on an average garden is perfectly contented with the present rate of actual money wages, and it is consequently nothing more or less than a waste of capital to increase the wage beyond what the coolies are contented to work for. That this scramble for labor is a mistake has been already proved in the Darjeeling district by the fact that just before the crush in 1865-6 three adjoining gardens competed steadily against each other for labor: if one raised the rate of wages, the other two capped that rate and so the game of brag

went on until two out of the three were sold for less than and old song, and the third very narrowly escaped the same fate.

It is, of course, impossible to lay down a hard and fast rule, as very few garden are similarly circumstanced as regards nearness to bazaars, wood, water, nerricks, extent of ground given for cultivation and other details; but it may be safely fixed as a rule to which there can be no exception that the present rate of R5·8 a month for men, and for women and children in the same proportion, is quite an ample money wage. Any increase beyond these rates is more than the people want, and is, therefore a needless waste of money.

There is a reference to previous attempts to raise wages and the results :—

The result of the scarcity of labour in 1873-4 was that many of the old gardens as well as the newly opened ones suffered heavily from want of a sufficient available labor force to keep the plants, both old and new, free from undergrowth, and it is a fact remembered by many that at this particular time it was no uncommon thing for the pluckers to be armed with sticks or reaping hooks to beat or cut down the jungle before they could get at the tea bushes to take the leaf off. This too was at a time antecedent to the extensive introduction of machinery into the district, and when a large number of men had to be employed in the factories to roll off the leaf by hand. This did not matter so seriously then, as the market was good, and fully 6d per lb. more was realized for tea than is obtainable for a much better article now, or is likely to be realized in future.

"Jungle" in the above means rank weeds, especially the grass we call *iluk*. Our readers will see, that, when p ces of land come to be considered, cooly wages in Darjiling are not lower than in Ceylon.

FLOWER DISTILLATION.—If, as alleged in Bombay, the French have prohibited the import of *mhowa* flowers (*Bassia latifolia*), they are interrupting what is now a tolerably large trade. Last year India exported nearly 6¾ lakhs worth of *mhowa* flowers. Most of it goes to Marsellies for distillation. In India a very unpleasant sort of liquor is distilled from the flowers; but in France, after a long course of experiments, a means has been found of rectifying the spirit, and the result is very good alcohol. A man might make his fortune by finding how the French do it, and practising the art in India.—*Indian Agriculturist.* [There is money to be made in Ceylon too in this line.—ED.]

A WONDERFUL NEW COTTON PLANT.—Attention is now attracted, says an Atlanta, Ga., despatch, to a new sort of cotton plant, which bids fair to prove immensely valuable. For many years A. A. Subers, of Macon, has been carefully experimenting to hybridise the cotton plant that grows wild in Florida with the common okra. The cotton plant used is of that species which is found in the lowlands of the Caloosahatchie River. The new plant retains the okra stalk and the foliage of the cotton. Its flower and fruit, however, are strikingly unlike either cotton or okra. The plant has an average height of two feet, and each plant has only one bloom. This is a magnificent flower, very much like the great magnolia in fragrance, and equally as large. Like the cotton bloom, the flower is white for several days after it opens, after which it is first pale pink, and gradually assumes darker shades of this colour until it becomes red, when it drops, disclosing a wonderful boll. For about ten days this boll resembles the cotton boll, and then its growth suddenly increases, as if by magic, until it reaches the size of a big coconut. Not until it reaches this size does the lint appear. Then its snowy threads begin to burst from the boll, but are securely held in place by the okra-like thorns or points that line the boll. One inexperienced picker can easily gather 800 lb. a day, and fast hands much more. Were the only saving that of labor in gathering the lint, the result of Mr. Suber's experiment would entitle him to the everlasting gratitude of the Southern farmer. But this is not all—there are no seeds in the lint. Each boll produces about 2 lb. of very long staple cotton, superior to the Sea Island, and at the bottom of the boll there are from four to six seeds, resembling persimmon seed. This new cotton, therefore, needs no ginning.—*Boston Journal of Commerce.*

PITCH PINE.—Pitch pine has been largely used for London roads. The export of this wood from Florida is very great, as it is highly esteemed in England; it is called pinus rigida, and General Morgan, in his work on Forestry in Southern India, strongly recommends that it should be tried here. It is certainly better adapted to this climate than was Pinus Maritima to the lowcountry. We sadly need a variety of useful imported trees. E. Globulus or Blue-gum, was a great boon, but that was introduced by a private gentleman. Let Government make a few trial plantations of useful imported trees. Some private individuals have done much for these hills in importing valuable trees, but experimental plantations should be the work of the Forest Department. We had hoped to see some change and some improvement in this line, with a Conservator up here, but as yet there is no sign.—*South of India Observer.*

DRYING FERNS.—A recent number of the *Indian Gardener* gives some useful hints on drying fern fronds. Of course, every one has his own way of going to work about it, but the difficulty which most of us meet with is to retain their natural colours in the same manner as is generally employed for obtaining herbarium specimens of other plants; in fact, ferns gives us very little trouble in this respect, that is, if well ripened fronds are selected for preservation, as they dry so much quicker than most other plants owing to the thin papery texture of their leaves. The writer gives the following instructions, and, if carefully carried out, will give satisfactory results. In the first place, the drying paper selected should be thick, unglazed, and of an absorbent nature, such as blotting paper or any other kind that absorbs moisture quickly. A convenient size is 12 inches by 18 inches, or certainly not longer than 16 inches by 24 inches. Place three or four sheets of paper between every layer of fronds, and where a large quantity has to be dried, a thin board should be placed after every ten or twelve layers, as this will render the pressure equal on every part. In order to keep the pinnæ in their proper place, the fronds must must be placed face downwards on the paper, and a top layer of paper placed on them. A piece of plank, an inch or more in thickness, should be placed on the top of all, and on this some heavy weight should be laid. As the paper gets moist from absorption, it will require to be changed at an interval of 24 hours, every three or four days. As soon as the fronds are quite dry, they should be gummed on to sheets of white paper.—*Indian Agriculturist.*

SUGGESTION ABOUT ORCHARDS.—Somebody will say, "How have you got peach trees twenty-seven years old in vigorous bearing?" Well, I'll tell you. I saw a suggestion in a Yankee newspaper, that if the white worm about an inch long was removed with a knife from the root of the tree, in November, or at any time, and some lime and ashes mixed and placed at the spot, it would help the peach tree. I had but ten left. I took my knife and "laid it to the root of the tree" where the flat-headed, maggoty-looking "varmint" was piling up the life-blood of the tree in the shape of glue, and I never stopped until I got out the last one from the ten trees, which were at the time twelve years old, and in a decaying condition, and piled up a peck of lime and ashes around the roots and the dirt I put back. What was the result? They recovered at once, put on the most beautiful green, and were loaded down for three years in succession with splendid peaches, such as they had never borne while in their best years. They have missed sometimes on account of frost, &c., but this last season bore well, and fruit free of worms. The process has been repeated three or four times since the first. Five peach trees treated this way are worth fifty let alone. I have put a great many trees to fill in old places and have extended my orchard; but after twenty-seven years of practical study and experience in this matter, I would say to one who was going to put out an orchard; don't buy too many kinds, don't prune too much, mulch the land with wood mould, or the woodpile chips or something else, if you have not the manure, and wash the bodies of your trees with soap-suds, and keep the sun from the bodies of your young trees. To show the importance of this shading part, just turn down one of your young trees to the north so that the sun can shine on the body, and see how soon the blister and the worm will set in.—*Southern Planter.*

FLY-MAGGOTS FEEDING ON CATERPILLARS.

A few months ago I had a caterpillar of *Papilio erythronius*, which I found on a lemon-tree. I put it into a card-box, and fed it daily on lemon-leaves. The box was covered with cloth *tied tightly all round the opening*. After some days, the caterpillar fixed itself to the side of the box, and turned into a chrysalis in the usual way. One day on opening the box, instead of finding the chrysalis changing into its usual colours and markings, it was dark all over. A few days more, on re-opening the box, I found six fully-developed cream-coloured maggots at the bottom of the box. I was rather puzzled to conjecture how these maggots got into a box three inches high, with a bit of cloth tied all round the opening. I put the maggots into a little box with some earth under a tumbler. They immediately buried themselves in the earth. In a few days I found six chrysalides, and some days later there were six ordinary house-flies buzzing within the tumbler. I then examined the dark chrysalis of the *P. erythronius*, which was evidently dead, and found it only a *shell*. All its interior had been consumed by the six maggots. It is evident that these maggots in their infant stage had already been in the body of the caterpillar when I boxed it. The latter had gone through its transformation as if nothing was the matter with it, although, if one could have interrogated it, probably it would have complained of mysterious gnawings and crecpings in its interior. A time, of course, came when, for want of nerve-centres and other organs, the chrysalis could not go on with its development into the perfect Papilio. The six maggots having had a full meal, found their way out of the Papilio's chrysalis in order to undergo *their* transformation.

I knew that the larvæ of the Ichneumonidæ fed on the live bodies of caterpillars, but I did not know that the larvæ of the house-fly did so also.—E. BONAVIA.—*Nature.*

CINCHONA LEDGERIANA AS A SPECIES.

At the last meeting of the Linnean Society, a paper was read by Mr. E. M. Holmes on "*Cinchona Ledgeriana* as a Species." The author stated that, judging from the variable character of the bark met with in commerce under this name, some of which, like that from Darjeeling, was clearly a pure calisaya bark, while others presented the characters of hybrids of that species with *C. officinalis*, he had come to the conclusion that a number of varieties and forms and probably some hybrids of *C. Calisaya* are now in cultivation under the name of *Ledgeriana*. A comparison of herbarium specimens from different localities pointed to the same conclusion. The history of Ledger's seed was traced to prove that this must have been the case; the original seed having consisted of the product of about fifty trees and having been at first considered as calisaya, and placed under circumstances by which they were almost certain to have been subjected to the influence of hybridization. The author claimed that sufficient attention has not been paid to the characters presented by the bark, and expressed his belief that if these were studied in conjunction with those afforded by the flowers and fruit, the various forms now cultivated under the name of *Ledgeriana* would be more easily defined and recognized. On comparing the essential characters mentioned by Dr. Trimen as distinguishing the *C. Ledgeriana*, Moens, he found that they were to be met with in other forms of calisaya, the small flowers being found in the var. *pallida* of Weddell, and leaves of exactly similar shape in the var. *microcarpa*, Wedd., while the drooping flowerbuds did not occur in a specimen received from M. Moens, by Mr. J. E. Howard, a flowering twig of which was placed upon the table at the meeting. He, therefore, concluded that if there was anything characteristic in the habit of the tree to enable it to be easily recognized by sight it should be regarded only as horticultural form, referable to *Cinchona Calisaya*, var. *pallida*, as a form "Trimeniana." Judging from a specimen of the bark received from Mr. T. N. Christie, of Ceylon, for the Museums of the Pharmaceutical Society, half of which had been analysed by Dr. Paul, he considered that the analysis bore out the opinion he had previously formed of this particular bark, and in which Mr. G. E. Howard and agreed, viz., that it was a hybrid between *C. calisaya* and *C. officinalis*.—*Pharmaceutical Journal.*

THE NUTMEG.

Of immense commercial importance is the Nutmeg tree, Myristica moschata, or M. aromatica. It is also ornamental by its clusters of berries or fruit. The plant is not commonly met with in this country, and it is seldom grown except in botanical or officinal collections. Its cultivation, however, is not difficult. It thrives in a sandy loam and brisk heat, and cuttings strike freely inserted in sand and placed in heat under a bell-glass.

Of the Nutmeg tree Dr. Hogg has written as follows in his "Vegetable Kingdom:"—"It is a native of the Moluccas and neighbouring islands, but is now cultivated in Java, Sumatra, Penang, the Isle of Bourbon, Mauritius, and other parts of the East, and in Cayenne, Martinique, and some of the West India islands. It attains the height of 30 feet, with a straight stem and a branching head. The leaves are oblong-oval, glossy on the upper surface and whitish beneath, and with an aromatic taste. The flowers are male and female on different trees, insignificant, and of a yellowish colour. The fruit is round or oval, about the size of a small Peach, with a smooth surface, green at first, but becoming yellow when ripe. The external covering, which may be called a husk, is thick and fleshy, containing an austere astringent juice; becoming dry by maturity, it opens in two valves, and discovers the nut covered with its aril, or mace, which is of a beautiful blood-red colour; beneath the mace is a brown shining shell containing the kernel or Nutmeg.

"A plantation of Nutmeg trees is always made from seed, and it is not till the eighth or ninth year that the trees produce flowers. The sexes being on different trees, after the plants are two years old they are all headed down and grafted with scions taken from the female tree, reserving only one male stock for fecundation. The natives of the Moluceass gather the fruit by hand, strip off and reject the pulpy husk, detach the mace carefully, and expose it to the sun, which soon changes its beautiful blood-red colour to a light brown; it is then sprinkled with sea water to render it flexible and preserve it. The nuts are first sun-dried and then smoked, until the kernels rattle against the shell. This shell being removed, the kernels are dipped twice or thrice in lime water, laid in heaps for two or three days, wiped, and packed in bales or barrels. The unripe fruit of the Nutmeg is frequently preserved in sugar in the East; and before doing so it is necessary to deprive it of its acrid properties by soaking it in spirits."—*Journal of Horticulture.*

SINGELL TEA COMPANY (LIMITED).

THE following is the report by the Managing Agents to the shareholders of the Singell* Tea Company (Limited):—The Managing Agents beg to submit herewith the Statement of Accounts for the half-year ending 30th June last, with a corresponding statement of the similiar period 1883.

Season 1884.—The District has suffered from a severe drought, extending from the end of the rainy season of 1883, until late in the spring, which has seriously affected the garden during the early portion of the season in respect of outturn. During May an improvement took place in the weather, but a scanty rainfall has characterized the whole season. Even under the comparatively adverse circumstance of weather the outturn is equal to that of last year, and the Company's property is in a sound condition.

The following is a statement of Tea made from the commencement of the season to 31st July, for the present and two previous seasons:

	1884.	1883.	1882.
Singell lb.	... 105,141	106,714	124,920
Kurbla „	... 36,898	35,133	35,011
Total lb.	... 142,039	141,847	159,931

The quantity of Tea received in Calcutta to date is 128,160 lb. of which 122,211 lb. have been sold here at a nett average of annas 0-8-2 per lb.

Garden.—Under date 6th August, the Manager reports as follows:—

Cultivation.—The Gardens are in nice cultivation, and

*Singell is a steep featured estate at Kurseong, about half-way from Silliguri to Darjiling, altitude about 3,500 feet. —Ed.

we have so far escaped much wash. I have from time to time, as we had spare labor, made stone terraces replaced as much as possible, soil in the steeper places, which have suffered during former years.

Buildings—are all in good repair.

Coolie Lines—are also in good condition.

Machinery—has all worked well. The engine purchased from Mr. Scott is a very powerful one, and gives satisfaction.

Manufacture and Outturn.—This year's crop has suffered much through the extraordinary short rainfall we have so far met with.

The season open with a long drought, and we have since been gradually dropping more and more behind even the scanty rainfall of last year. The fall here this year up to August 2nd is 68·82 as compared with 92·02 of last year, and 32 inches below the average fall of the past eight years. We suffered a good deal from Red Spider early in the season, but this is now leaving us. A good deal of rain had fallen during the last few days, and the weather has been favourable.—*Indigo and Tea Planters' Gazette.*

BRITISH NORTH BORNEO.

[BY A CEYLON PLANTER.]

I paid a visit to the Government Agricultural Gardens at Silam, and reported on them to Government. Silam is a small village of a few houses situated at the foot of a fine hill 3,000 feet high that is called Bude Silam, and it is here that the gardens are opened. The soil is quite different from anything I have yet seen in Borneo, and is a rich, black, friable earth, rather mixed with sand. Contrary to what one sees elsewhere, here there are large quantities of stone in and about the beds of streams, some of which look very much as if they had experienced volcanic action at some period; in fact, an island within sight, called Pulu Gaya is marked in the Admiralty charts as being volcanic. The streams are very good, with fine clear water, while Darvel Bay, as regards beauty, is one of the most beautiful pieces of water one could wish to see, with its surface dotted with little islands, and here and there a "prow" with its particolored sails skimming along before the wind. Coral is abundant in the bay, which adds a peculiar blue to the water, which appears to be as clear as if it was distilled.

The Gardens contain cocoa, Liberian, Java, and Coorg coffee, as well as our old love of Arabia. Further on we find cardamoms, rubber, tea, sugar, palms, cinnamon, cloves, nutmegs, sapan, pepper, croton, and many other economic plants. Cinchona has proved to be a failure, due, I believe, to the elevation being too low. Ceylon cocoa—from Pallakellie, I believe—was growing most healthily, while the Liberian coffee, excepting its inequality beforementioned was fine both in fruit as well as blossom. Tea was a failuro, even though the hybrid species had been introduced. Croton was growing most luxuriantly, likewise pepper and citronella grass, Speaking of grass reminds me and I noticed our wellknown Mauritius grass *in flower*—a sight I have never seen in Ceylon, though I have seen hundreds of acres of this plant. The gardens remind one much in their general appearance of a Ceylon coffee estate, with its well laid-out roads and evenly traced drains, all of which reflects the utmost credit on the Ceylon planter who did the work, from the very selection of the land to the planting of the same, and, with uneducated labor, the trouble of transporting seed, not to say importing it, must all be considered as difficulties unknown in this country. So far the Experimental Gardens have answered the question of what will grow and what will not grow, though it is a pity small gardens of a similar nature are not started at the various stations to test the problem with different soil conditions. The question as to the "paying" of these products can, of course, only be solved by time, labor and money; but for the present the cost is much in the way, and other systems of working would have to be employed in order to bring it within reasonable bounds. At the time I was there, there was no European in Silam, owing possibly to the smallness of the station, but this appears to me to be a pity, as it needs development, and, with such a soil as the place possesses, more might be done.

Later I visited a small plantation near Sandakan on the Sabooga river, where Liberian, cocoa, and Manilla hemp were flourishing. The area was too small and the planting of too recent a date for me to pass an opinion beyond that great praise is due to the managers for the careful way in which the property had been opened, especially as there was, I believe, some difficulty at first to procure good water, which had caused sickness among the coolies. The Manilla hemp appeared to be thriving most healthily, each stock having already sent up shoots in true plantain-tree style.—"Local Times."

CHINA TEA PLANTATIONS.

The *Home and Colonial Mail* says:—The Consular reports from China just issued by the Foreign Office refer to the state of suspense existing in China when the war question with France and the adverse effect of this on trade has been considerably affected by the probabilities of war. There are, however, other influences at work, which may greatly alter the conditions of the trade in the course of a few years. It is asserted, for example, that a general deterioration is going on in the China tea plantations, which are year by year wearing out, the soil and the shrubs alike becoming exhausted. Mr. Alabaster, of Hankow, Consul, notices this allegation, and is inclined to doubt its truth. So far as we can learn, the system in use is the same that has prevailed for centuries, and though, of course, individual plantations, and even districts, may become exhausted, he sees no reason to think that there has been any sudden and general failure. Still, old teamen declare that it is so, and that they never see now such teas as used to be produced twenty years ago. Whether as good tea is to be had as formerly or not may be an open question, but it is certain that we do not buy for use in England even the best that can be bought. The highest price given during the last season was 2*s.* 6½*d.*, but, according to Mr. Alabaster, no native gentleman would think of asking his guests to drink tea at less than double that price, and a wealthy host would probably offer an article of much higher value.

Mr. Alabaster's opinion is that if we would only pay the price we might obtain a much better quality of tea under the modern conditions of transit than was formerly available. Just as wines are made up in Spain for English consumption—to stand the sea voyage and to suit the supposed taste of Englishmen—so teas are made up in China. The article is prepared to endure a possibly six months' voyage by "heavy firing," a process which makes the leaf utterly unacceptable to native consumers. Now, however, that the transit can be made in thirty or forty days, there is no reason why teas cured in the Chinese fashion, for the drinking of Chinamen, might not be brought to England. Mr. Alabaster anticipates that the public would look at them askance at first, but (says he) "they are so infinitely better than the charred, perspiration-saturated faced and doctored teas they have got used to, that there can be little doubt they soon would be preferred, as they are here, where natives scorn the very thought of drinking the spoilt produce they sell to foreigners." The haste to buy, which has long prevailed in the tea trade, is disappearing except in certain ports. Foochow is one of these. Although the market only opened on June 11, there was such a rush that within three weeks, by July 1, eight steamers, conveying 4,500,000 lb. of tea, had left for London. This haste to be home first is clearly, however, more a matter of habit than of necessity in these days.

All the consular reports indicate that the success of Indian Tea in the home and other markets is having a serious effect on the Chinese trade. "The duty question," says Mr. Sinclair, reporting from Foochow, "handicaps all transactions terribly in competition with India. The equivalent of 1½*d.* a pound export duty, imposed by treaty, and improved on to the extent of 1*d.* a pound by the Chinese Government for inland and *li-kin* duties, becomes yearly more and more difficult to be borne, and that alone "must tend to throw the production of tea into India within a few years." The same Consul reports that during 1882 the Calcutta Tea Syndicate "rushed" the Melbourne market, so that the Australians would not

touch tea from China in the early part of last year, and at no time during the year were they active buyers. Mr. Alabaster, who disputes the assertion that China teas are not so good as they were, admits that they "do not hold the position they once did, compared with their Indian rivals." After all, however, the China grower will still have an almost unlimited market in his own country, if Mr. Alabaster be correct. The tea consumed in foreign countries constitutes, he states, but a very small proportion of the quantity grown; for, putting the estimate of the native population much lower than usual, they still far outnumber the tea-drinkers abroad; and tea-drinker for tea-drioker, they require at least twice as much per man.

TEA CULTIVATION IN NATAL.

We learn by the *Times of Natal* that a meeting was held in the Maritzburg Town Office on Monday afternoon for the purpose of considering whether the tea industry can be developed in the neighbourhood of the city.

Mr. R. Topham, in opening the proceedings, said that if the amount was expended on the soil of the colony which was generally expended in other places, it would render it the most productive country in the world. They had met that afternoon to consider whether it would be desirable to develop the cultivation of the tea plant in the neighbourhood of the city, and with that purpose would call on Mr. Hulett to give the meeting the benefit of his experience.

Mr. Hulett said that perhaps it would be better for the meeting to put questions to him. He was a firm believer in the industry, and, as was well known, he had invested his all in it. He had already 74 acres under cultivation, and would make it up to 100 acres in the course of two or three months; and two or three neighbours had gone into the trade, and there were now over 150 acres under cultivation. There were tens of thousands of acres on the coast where tea could be grown. It was, of course, a question whether tea would grow as well in the upcountry lands as on the coast. That he could not say; experience only would show. There might be advantages accruing to the formation of small tea gardens in the neighbourhood of the city which they on the coast did not possess. There might be considerable benefit to be derived in the picking season by the employment of young children, of whom there were so many in the city who could be so employed, both European as well as others. Further, the cultivation might be cheaper than on the coast, where they had to depend on manual labour only, and near the city much might be done with machinery. He thought also there would not be the same difficulty with regard to weeds. It was likely that a less amount of leaf would be obtained than on the coast, but it might still be made a paying industry, and if successful would become second to none. He had that morning visited Wilgefontein, where he had sent a sack of seed. He had found the seed in the nurseries coming up very well. While there, he saw a large tract of land which would grow tea well if they did not have more frost than they say they did. It had been said that he had a monopoly of the tea trade; but the more tea there was grown the sooner would the price go down to export rates. He did not believe in working for one's private ends in a country like this. Several questions were then put to Mr. Hulett, who gave answers which are embodied in the following. He had no frost on his land, so that he could not say for certain how many degrees the tea plant could stand, but in China it bore a very large amount.

Mr. Topham said that tea plants which had been given him by Mr. Hulett had thoroughly stood the frost of the present winter, which was the most severe he had known for 20 years.

Mr. Hulett, continuing, said that he did not say there would be less leaf from the up-country districts than from the coast; but on the latter the spring came earlier and the summer lasted longer, and therefore he thought they would get more leaf than upcountry. If in the neighbourhood of the city they got as much leaf as he did, there would be no question as to the success of the enterprize. Irrigation would be necessary, not in the winter—as the water would probably turn to ice round the plants—but on days like the present, when the water and sun would have the effect of a shower of rain. Then they must remember the system of pruning; if they wanted to get a lot of leaf they must prune in the winter. With respect to the class of tea to be grown, it was a well-known fact that Indian teas were driving the China out of the market. The liking for Indian tea was an acquired taste, and that was the tea being grown by him. They could not get from China plants more than half the amount of leaf that they could from Indian, and that was the reason why they grew the latter. With respect to the hot winds, they did not get much of them on the coast, but had never suffered any ill effects from them. With the south-east wind they sometimes had rain. He had found that in the exposed lands the edges of the leaves were slightly blackened. He would always advise that trees should be planted at the borders of the fields to break the force of the wind. His yield of tea was greater than anyting he had read of in India. The first trees that he planted from his own seed were planted in November, 1880. In two years he began to pick, and six months after he took 250lb. weight of leaves. In India 40lbs. or 50lbs. would have been a good return.

Mr. Hulett then read a statement of probable returns per acre, which has already been published in these columns.

With regard to the value of tea, he believed it could be grown to pay all expenses at 8d. a pound; but that would not leave much margin. Any company or private person could make it pay at 10d. or 1s. a pound for exportation, and he believed that the Natal-grown tea would fetch from 1s. to 1s. 3d. a pound in the London market. With regard to labour, whatever you do, do not employ Chinamen; they do not know how to make tea. They made it the same now as they did 500 years ago, and Indian tea was forcing the China out of the market. What was wanted first of all was an expert. He (the speaker) made tea, and knew there was something wrong with it, but could not find out what it was; but an expert could tell them at once. There was no doubt that kafirs could be easily taught how to pick the leaves. The soil must be good and deep; shallow, shale land would not do.

Mr. Barnes did not see why an experiment should not be made, and with that object would move: "That in the opinion of this meeting it is desirable to test the question as to the development of the industry in and near Pietermaritzburg, and that steps be taken to promote such experiment."

The resolution was duly seconded, and after a slight discussion was unanimously carried.

The following committee was then appointed to give effect to the resolution:—Messrs. Egner, Chapman, C. Matterson, Barnes, G. Thresh, and Joseph Baynes. Votes of thanks to Mr. Hulett and the chairman brought the proceedings to a close.—*Natal Mercury.*

BRAZIL.

REPORT BY MR. CONSUL STEVENS ON BAHIA, FOR 1883.—"There can be little doubt" Mr. Stevens says, "that the producing capabilities of Bahia are great, I may even say inexhaustible, and it seems regretable to one visiting any portion of the interior to see crops of all descriptions of produce literally rotting for want of roads and easy communication. I have myself seen cotton, dividivi (the value of which is unknown here), sugar cane, coconuts, and coffee in an advanced state of decay, having been abandoned consequent on the closing of paths by heavy waterfalls in the season of collection. Roadmaking is almost unknown, and such paths as one meets are made by clearing the bush which grows again in a few days. Few persons care to travel by these insecure paths unless armed, where crime—unpunished in nine cases out of ten—increases as the emancipation of the slaves advances. The hope of proper cultivation and large crops and due prosperity may be summed up in the following:—1, Courts of Law; 2, Magisterial Courts with power of summary punishment; 3, Crown prosecution in criminal cases; 4, Roads and more reasonable duties." The establishment of sugar factories is to be proceeded with, and eight spots have already been fixed upon where it is proposed to erect premises capable of turning out three to four hundred tons of sugar per diem from sugar cane, for the supply of which arrangements have already been made. It may be open

to question whether the energy of those interested—which, according to the Consul, "is not merely one of self interest"—will be repaid in the manner they anticipate, when the great continental manufactories are turning out more of the commodity than is required for consumption, and bounties and drawbacks are resorted to as a means of fostering a trade which could not thrive on fair principles. However, some of these new factories are so far advanced as to be in readiness for the machinery which it is hoped may be at work by November or December; and the Consul remarks that "shareholders will, no doubt, be happy to learn that the investment cannot but prove remunerative under the previso of the zealous and energetic administration already alluded to." There seems more reason for expecting future good from the development of the railway network which, by the accounts the report gives, is rapidly proceeding; not only benefiting the interior, but also tending to increase the export trade of Bahia. Having given the figures of import trade, Mr. Stevens says:—"The duty exactedamounted to a little over one-fourth of the values. A statement of the trade of the port of Bahia may be interesting, as showing the importance of that of Great Britain over any other nationality:—

Country.	Exports to 1882-83. £ s. d.		Imports from 1882-83. £ s. d.	
Argentine Confederation	6,224 3 4	...	11,076 7 9	
Austria-Hungary ...	955 2 4	...	20,963 14 10	
Belgium	53,312 15 4	...	14,594 6 3	
Chili	58 7 11	...	—	
France	180,095 6 0	...	241,164 16 3	
Germany	458,389 7 4	...	223,523 6 10	
Great Britain ...	254,899 17 5	...	1,110,094 10 4	
Italy	2,905 19 10	...	—	
Portugal	25,425 5 4	...	180,341 14 7	
Spain...	707 15 7	...	8,158 7 6	
United States of America	195,616 14 6	...	129,641 8 4	
Uruguay	2,410 11 1	...	68,534 19 3	
West Coast of Africa	13,475 12 11	...	15,334 13 11	
Total...	...£1,194,206 19 3		£2,023,428 5 10	

In conclusion the report says:—Possessing diamonds, gold, silver, amethyst, copper, lead, iron, potash, alum, saltpetre, peat, coals, timber, a vast bay, a splendid port, navigable rivers, a soil and climate capable of growing anything and everything known in agriculture, without much outlay, and cheap labour, Bahia has no doubt a great future before it. These sinews of great wealth, through the inertness and apathy of its owners, whether State or private, have been sadly neglected over more than 350 years. The new railways and the new central factories and tramways are indications that there is a reaction at last, and, in the interest of those concerned on this side, and those in Europe trading with them, among whom England holds the first place, let us hope that the past indifference to the good things of this world will soon be retrieved.—*Chamber of Commerce Journal.*

THE TRADE IN ORANGE PEEL.

Christmastide wakes up and important trade in products of the Orange family, and especially does one of these put in a prominent appearance at this time, and that is the rind or peel of the Citron in its form of candied peel. Fruiterers and grocers make a goodly display of dried and candied fruits just now. The public have little conception of the large commerce carried on in the peel. Let us form a rough estimate of its consumption as candied peel at this season. There is scarcely a household in the kingdom that does not have one or more plum puddings. Assuming that there are 7,000,000 families (to say nothing of the floating population in hotels, ships, &c.), each of these would consume, say, half a pound of peel for their puddings, which creates a demand for 1,500 tons, and we import more than this quantity from Italy alone. It is the Cedrat, a variety of the Citrus medica, which principally supplies the Citron peel of commerce. The large fruits are known under the name of *poncires* in France. But it is not only the peel itself of these fruits that is useful, valuable essential oils are obtained from the rind of many species. The large variety of the Citron when candied furnishes the chief part of the citrionate or succade. The rind of Citrus aurantium yields the essence of Orange of Portugal. The fruit rind of Citrus bergamium, a graft on C. vulgaris, with a fine aroma, is abominably bitter, furnishes Bergamot oil, and the Mellorosa variety an exquisite confiture. The pulp and thick rind of the Shaddock, C. decumana, can each be used for preserves. The sweet Lemon, Citrus Limonum, with a thick and pale rind, serves for particular condiments. The thin smooth aromatic peel of the ordinary Lemon also furnishes condiments and the production of an essential oil. The plants of the Orange family exhibit in every part vesicular glands or receptacles of oil, which abounds particularly in the leaves and in the rind of the fruit. It is this volatile principal which makes these trees so oderiferous, and gives that stimulant action which the various parts exercise on the animal economy.

Orange peel readily yields its otto by simple expression. The fruit of both the Bigarade and the sweet Orange is used, the former yielding the best product. It is a light yellow liquid, and has a strong aroma peculiar to the fruit from which it is obtained. Its general properties are the same whether derived from the sweet or bitter Orange. Of all ottes it is the most difficult to preserve; when exposed to the air it becomes worthless with great rapidity. The Seville Orange (C. Bigaradia) differs from the sweet chiefly in bearing a fruit rugged on the surface of a deeper hue and with a pulp sour and bitter instead of sweet.

The Seville Oranges are principally used for marmalade. The rind of the Bergamot yields, both by pressure and distillation, the volatile oil called Bergamot. One hundred fruits are said to yield 2½ oz. From the rind of the sweet Orange an essential oil called oil of orange is produced; an inferior kind called Neroli oil, is obtained from the rind of the bitter or Seville Orange. The value of the essences obtained from the Orange family shipped annually from Messina exceeds £170,000. The preparation of preserved or candied Citron used to be carried on in Leghorn on a large scale. In a good year about 5,000 boxes to more than 1,000 tons are shipped. Refined sugar alone is used, and enters into the composition in the proportion of 80 per cent., and more sugar was lost and used up in the course of the manufacture than was allowed for by the drawback, hence it does not pay at present to preserve the peel, which is shipped in brine. Italy sends us, on the average of years, about 3,750 tons, worth £60,000.

The fruit of the Citron, cut in two or three pieces of about 1 lb weight each, are packed in barrels of brine to insure their preservation. From Sicily, 50 to 100 tons are shipped in a year at the price of about £3 per cwt. In Greece and the Levant the parings of the hundreds of millions of fruits consumed were formerly thrown away but some Sicilians have of late years introduced the art of preparing the essential oil. In 1872 the quantity of essences shipped from Messina was 307,000 lb. One thousand Lemons, price 9s., will yield 1 lb. avoirdupois of essence; 350,000 lb. to 400,000 lb. avoirdupois of essence extracted from the peel of the Citron are often shipped from Messina in a year. Each tree will often yield in value £4 of fruit.

The Cedrat has been much cultivated of late years in Corsica, the prices realized for the produce under this branch of industry are most remunerative. About 1,000,000 lb. of fruit or candied Citron peel, and 2,700,000 lb. salted, is exported annually. The Cedrat forms a considerable article of commerce in the island of Naxos. About half a million fruit are sent annually to England, but many millions might be shipped. They are sold when large at about 5d. each. The want of labour prevents their being prepared on the spot. Malaga ships about 1,000 lb. of Orange-peel to different ports in Europe for making liqueurs and syrups.

When the time for preserving for England comes the fruit is taken from the pipes, and boiled till soft enough to admit of the pulp being scooped out. The rind is then laid in tubs or cisterns, and melted sugar poured over it. Here it lies for three or four weeks, and then the sugar is drained away, and the rind placed on trays in a room constructed for the purpose. It now assumes the name of dried peel, and is stored away in boxes till wanted for candying.

New York imports Orange-peel largely from different parts of the world. In 1877 the imports were to the value of 9,000 dols., since then they have risen in value to 12,000 dols. The shipments from Havre to New York by steamer are frequently 200 sacks, value about £200.

The fruit and rind of the bitter Orange, C. Bigaradia, is also used for candied Orange-peel. The rind is thicker than that of the sweet Orange, and much more rich in aromatic oil, so that there is always a great demand for it for making essential oil of Orange, flavouring extracts, bitter preparations, and liqueurs. The well known and delicious liqueur known as Curaçoa is made in large part from a distillation of the bitter Orange-peel. Many people imagine that this liqueur comes from the island of Curaçoa, but this is a mistake. The Dutch make it in Holland mainly from the Orange-peel imported from that island, which is one of their possessions, and have named it after that island as a sort of guarantee of its quality, for undeniably the finest Orange-peel in the world comes from there. The bitter Orange-peel is one of the principal items of export from Curaçoa, indeed it ships little of any importance except this peel, Divi-divi, and Aloes. Hundreds of thousands of pounds of this peel are sent annually to Holland. In Amsterdam there is a regular Orange-peel mart, where saucers full of peels are set out upon long tables, and testers go among them selecting for purchasers. Such experience have these men that they can tell simply by breaking and smelling a bit of peel just what part of the tropical world it comes from, and that from Curaçoa always commands a higher price than any other.—P. L. S.—*Gardeners' Chronicle.*

SUGAR CULTURE IN MANILA, PENANG, AND CHINA.

The following letter, originally published in 1881, in the *Hawaiian Gazette*, is extracted from a United States Consular Report. The writer, Mr. Robert Collard, is stated to be a civil engineer and Sugar Planter of large experience in Peru:—

"I crossed the China Sea in a small Spanish steamer, and within a week after leaving Shanghai found myself in the capital of the Philippine Islands. The first sight I had of these islands was a high mountain range on the island of Luzon, close to the entrance of Manila Bay. Although within one day's journey from the capital, these mountains are inhabited by savages. The day is very large, but the water is shallow. Manila is located at a point where a small river enters the bay. This river is navigable for small steamers, and comes from a most extensive lake (over 40 miles long). The city proper is on one side of the river, and the commercial town on the other, the post authorities on one side and the custom-house on the other. The latter is, of course, on the side opposite the commercial quarter. There are strict passport regulations, and the whole tendency of the government is to cause inconvenience and delay. The European population in this city is very small. There are about 80,000 Chinese, and a still larger number of mestizos. The total population of Manila is said to be about 300,000, and of the whole of the Philippines 6,000,000. I did not stay long in the city, but visited several of the principal Sugar districts. This industry is carried on with great activity, the annual export amounting to 160,000 tons. It is all made on small plantations and in the most primitive manner. The provinces nearest to Manila are especially backward in the art of Sugar-making. All they know of it seems to have come from China; stone crushing mills imported from that country are still to be seen at work although they have given place to iron mills in most places. The greater number of crushing-mills are driven by buffaloes, but small steam-mills are largely employed. A mill having rollers 36 by 18 would be considered rather a large mill in the island of Luzon. A few cast-iron pans constitute the rest of the Sugar-house. Vacuum pans, centrifugals, and even pumps to elevate the cane juice are not used. The cane juice is of a very good quality and easily worked, but the Sugar extracted by these primitive methods is of a most inferior quality. I saw one place where the juice was being boiled down just as it came from the mill, no attempt being made to skim off the impurities. After the water was evaporated, the Sugar, while still hot, was packed into large grass bags. I believe that occasionally earth or sand is mixed up with the cooked mass to make it weigh heavier. There are many places in the Philippine Islands where a much better article is made, yet nowhere, except on one plantation on the island of Negros, is any Sugar made that could in any way be compared to your Sandwich Island product. The cane mostly cultivated is the red Java; the maximum yield per acre cannot be put down at much over two tons. One and one-fourth ton is as near as can be stated for an average good crop, and this is from plant cane, for rattoons are seldom cultivated. The land is only cultivated on the surface; the plough in common use is a very small one drawn by a single ox or buffalo; such an appliance can never touch the subsoil. No irrigation is required, the rainfall being abundant; the canes are planted very closely, about 2·6 from centre of the rows, and the cuttings laid close together near the surface. Planting commences at the same time as the crushing, about December or January, and this is the dry season, the wet season commencing at about May, by which time the crop has to be off. After this I imagine there is very little done to the growing canes; they are never stripped of their dead leaves, and consequently do not get a fair chance to grow. Whenever I questioned and planter about those operations, that we consider essential in other countries, the reply was, '*Mucho trabajo, señor.*' 'Too much work, sir.' In short, it is a land of small Sugar canes and of bamboos of unrivalled growth. Nature is most prodigal in this land—there are no narrow alleys, but a magnificent expanse of level country stretching toward the mountains, intersected by navigable rivers, and offering the greatest facilities for the construction of roads or railways. The timber is of excellent quality and large growth. I saw a table cut from a solid plank that was over 6 feet wide and 15 feet long without a crack or flaw. Then the lofty bamboos that give such a pleasing appearance to the landscape supply the natives will all the material they require in the construction of their houses. And now for the people. You will expect me to describe them as a very indolent set of fellows. In such a tropical country, of course, no one wants to work more than he can help; yet the native races of these islands have many good points. I was rather pleased with them on the whole; and think that if they had been under Anglo-Saxon rule or influence, instead of Spanish, a great deal more might have been made of them. The progress they have made is perhaps due more to the Chinese element than the Spanish. Chinese have emigrated to these islands for many years back; they intermarry with the native women. The mestizos resulting from these marriages seem to retain the best qualities of both races. They are industrious and enterprising, possess all the shrewd business qualities of the father, and retain the good physique of the mother. Nearly all of the planters belong to this class, and very few of the pure-blooded natives rise above the condition of labourers, while the pure Chinese remain in the towns. Very few Spaniards or other foreigners engage in planting—the former come out as Government officials, the latter as traders. Spain has never made the least attempt to develop these islands; but it is only just to say that at the present day she protects the labourer from any abuse or ill-treatment from his employer. There are about 5,000,000 of natives who pay tribute to Spain; but the country is large and labour very scarce in some parts. It would be no use in your looking in this direction to supply your plantations with field hands, for although the men are desirable, the Government would oppose any attempt to take labourers out of the country. While in Swatau, China, I was fortunate enough to get an opportunity to visit the country districts in company with a gentleman who speaks the dialect of that part of China; I went there to see the Chinese method of cultivating the Sugar cane, their system of treating the cane juice. Many of the mills were at work, and I also saw every operation relating to tillage of the soil and planting. The Chinese treated me most civilly everywhere, and afforded me every opportunity for observing their work. Now here we are in the birthplace of Sugar-making, and probably witnessed the same operations that were carried on centuries ago. A Sugar house here is a conical building made of canes and straw; in the centre is the crushing-mill, a cumbersome machine, consisting of two stone rollers placed vertically in a strong wooden frame; on the upper parts

of the stones mortices are cut, into those of one cylinder wooden teeth are inserted, which work into corresponding cavities in the other cylinder. The axles are of wood, one of them being prolonged above the frame; into this is inserted a long beam, to which two oxen are attached. The canes are only partially crushed at the first passing, but they are taken back and repassed between the rollers several times. The cane juice is carried in wooden buckets to the boiling house. This is a small shed attached to the mill house. Here are three small cast-iron pans, about 2 ft. 6 in. in diameter, set in a triangular form over the furnace. The latter is a sort of oven with the bottom of the pans coming through the crown; it has no flues or chimney; the same hole through which the fuel is fed also serves as an escape for the smoke, which finds its way out of the building through a hole in the roof. When the Sugar has been cleaned by the use of lime and skimming, it is either run out into shallow wooden trays and stirred up while cooling to prevent the formation of grain, or else it is run into earthenware pots. By the first method they produce a very fine-grained brown Sugar, containing all the Molasses, but in a form that will not drain; it is, in fact, concrete in a powdered form. The Sugar run into the earthenware pots is not cooked to so high a point; some of it has a very good grain and makes excellent white Sugar when clayed. Outside is a busy scene. The canes are being carried in bundles to the mill house with all the leaves and tops on. At the door are numbers of men, women, and children sitting down among the heaps of cane, cutting off the tops and leaves; these are all made up into separate bundles; the tops are used for seed and the leaves for the cattle. The Chinese waste nothing. They use for manure the refuse from the villiages, and import large quantities of bean cake. The land I saw was of poor quality and the canes were small. But near Canton I saw some fields of really fine cane, growing tall and straight. To obtain this they had placed rows of tall stakes at short intervals in the fields to keep the canes from falling; they also earth up. All their fields are kept very clean—no land is wasted or allowed to lie fallow. They alternate crops and use every effort to return to the soil what has been taken from it by each successive crop. Even the richer portion of the soil that is washed away during the rainy season, and deposited at the bottom of the water chaunels, is dug out and distributed over the poorer portions of their fields. These people are very poor, but they are most thrifty and do not suffer want. It was cold weather when I was there, and I especially noticed that all were comfortably clad—even the children of the poorest looked comfortable and healthy. The condition of the Chinese peasant working on his own little plot of land with his family around him, even the little ones helping to support the family, offers a most pleasing contrast to the life of the Chinese coolie working on the foreign plantations. These men are just as fond of home and children as we are, and will work honestly for their support; but once you sever a poor and ignorant man from all domestic ties you take from him every chance of developing his better qualities, life becomes a drudgery, and he breaks the monotony by seeking the excitement of the gaming table, or the dreams of the opium-smoker. On my way home I touched at Saigon, Singapore, and Penang. At the latter place I stayed a few days to visit the Sugar plantations in province Wellesley. This is a British colony, and is being worked with care, but the soil is not good, being mangrove swamps and reclaimed from the sea. All the cultivation has to be done by hand, and a greater number of field hands employed to produce a given amount of Sugar than in any country I know of. The canes look very well and are well cared for, but they are not so thick as I like to see. About two tons of sugar per acre may be considered the average yield. The only new process I saw was their system of clarification. A quantity of clay is mixed with the lime and stirred up in the clarifier; no scum is taken off, but the juice boiled up for a few minutes in order to mix up the impurities with the clay and lime. It is kept boiling while being drawn off, when in a short time all the impurities settle to the bottom; the clay being heavy carries down the light stuff, the clear liquor is then decanted off, and the water evaporated without any skimming. The juice has the appearance of being well clarified. In a clarifier of 350 gallons I saw 3 lb. of lime and 12 lb. of clay used as temper; the clay was ground up fine and mixed into a soft paste without grit. All these plantations use the vacuum pans and produce a very high class Sugar; but these canes give a very much larger proportion of Molasses than yours do. The labour for these plantations comes from two sources —the native Malay and the imported coolie from Southern India. There are also a few Chinese, but they mostly work on their own account and soon intermix with the natives of the country. I do not think that either the Hindoo or the Malay is as good a labourer as the Chinaman, and I gather from inquiry among the people from India that the Hindoos are altogether averse to emigration, and although the British Government still looks after them and gives them ample protection wherever they go, still they require much enticing before they can be induced to leave their native land. This labour question is always beset with difficulties. No matter from what country you import your men, so long as you want hands only you will get the scum of the population, fellows very low down in the social scale of their own people, men long addicted to idleness. There are always bad cases to deal with, bad children to educate, but it must be done. If your planters want really good servants, they must educate them up to their standard. If you would have faithful men, remove as much as possible the brutalising influences and try to make *men* of these fellows. I know that this may not be the best way to get the biggest crop off next year; but your are not working for next year alone, but for the future of Hawaii. Are there not children growing up about you? Do not be satisfied with any temporary remedy, as the bringing of a lot of men from China; try by every possible means to induce families of working people to settle on your estates. Make them feel they have a home. This may require time and patience, but for the man who has a large estate in the future it will pay. We are all responsible for higher and more serious things than the amount of Sugar per acre, and our duty to our hands is not finished by the payment of their wages. Of course I know that the man who starts a plantation for the purpose of improving the morals of the Chinese will soon become bankrupt, and I hold that the first lesson in morality is to teach a labourer to do an honest day's work; but much can be accomplished by not treating a man as a mere machine and driving him all we can, and by trying to counterbalance the brutalising tendencies of plantation life. It should lie on every man's conscience to do all he can for the men in his employ."—*Produce Markets' Review.*

VEGETABLE PHYSIOLOGY—CIRCULATION OF THE SAP.

A paper read by Prof. J. W. Robson, of Kansas, before the Mississippi Valley Horticultural Society, at Kansas City, January 22, 1884:—

The roots are those parts of a plant on which it is chiefly dependent for the supply of the moisture which its growth requires, and also serves to fix the plant in the soil.

That they absorb or *suck* up fluid with great rapidity may be easily shown. Take any small plant that is growing in the soil, and immerse its roots in a tumbler of water; if the plant be exposed to the light of day, and especially if the sun shine brightly upon it, the water will disappear very much faster from the glass than from one exposing the same surface, placed in the same circumstances, but without the plant; and if the specimen continues to grow and flourish, it will take up many times its own weight of water in a short period.

Of the water thus absorbed, a small proportion only is retained within the plant. The greatest part of it is sent off again from the leaves by a process termed exhalation, and the rapidity of absorption is, in part, governed by the rapidity of the above process.

If the leaves of a peach tree are stripped off, the fruit amounts to nothing. This fact was exemplified twice in Kansas during the last decade by the grasshopher invasion of that period. When the leaves of the grape or the gooseberry have been devoured by caterpillars, the fruit remains small and sour, and entirely worthless for the food

of man. If any healthy tree be persistently defoliated during the growing season, the tree will die. These facts led early botanists to form the opinion that leaves were merely "a clothing, or protection against colds and heats." Though this ancient theory is certainly true to a certain extent, still it is only a very small portion of the functions of the leaves. For it is in the leaves that those changes are effected by which the juices of the plant, relieved from the water—which is unnecessary for the functions of life—are rendered fitting for the nourishment and growth of the plant.

That leaves exhale moisture is proved also by the simple experiment of gathering the leafy branch of a tree, and immediately stopping the wound at its base with wax, or some fit substance, to prevent the effusion of moisture in that direction. In a very short time the leaves droop, wither, and fade. If the branch in this condition be placed in a very damp cellar, or immersed in water, the leaves revive and assume their original appearance. This experiment also shows their power of absorption.

The chief office of the stem appears to be to elevate the leaves, the flowers and the fruit into the most favourable position for receiving the influence of light, heat and air, for it is upon these that their full development depends. But this is not its only function; in combination with the roots and leaves (nature's wonderful laboratory) the crude sap, in its ascent, is divested of its rawness and aqueous matter and converted into nutritious sap, capable not only of supplying to the different parts of the structure the materials necessary for the maintenance of their healthfulness, for the repair of injuries, and for the production of entirely new parts, but also of furnishing the ingredients of those several products which the various tribes of plants may be said almost to create from the elements around them, and which are so valuable to man as articles of diet, as medicines or as articles of use in his various manufactures. All these varied substances originate in the ascending *sap* in its passage through the sap wood (*alburnum*) and flowing sap (*cambium layer*) by the exhaling process, in which the leaves play the most conspicuous part, for by them it is concentrated by the loss of its water not only into solid matter, but into those secretions which almost every tribe of plants produces peculiar to itself. How remarkably these secretions of different plants vary from each other, frequently in the same plant! The peach tree affords a familiar example of this; the gum of this tree is mild and mucilaginous; the bark, leaves and flowers abound with a bitter secretion than which nothing can be more distinct from the gum; the fruit is replete not only with acid, mucilage, and sugar, but with its own peculiar aromatic and highly volatile secretion, on which its delicious flavor depends; the pit also contains prussic acid to a certain extent. Can any one among the scientists tell us how the peach tree can form, collect, and keep separate such a number of distinct and discordant secretions?

In all exogenous trees the inner and older portion is much harder and dryer than the exterior. This change is due to the consolidation of the interior wood, by the deposition in its tissues of woody matter. The portion of the stem in which this has taken place thus acquires great toughness and durability, but it is no longer fit to perform any office in the living system save that of mechanically supporting the rest, since no sap can pass in any way through the now filled-up channels. The heart wood always displays a deposit of coloring matter not observable in the younger or outside layers. Thus in the wood of the apple or pear, the handsome orange color of the heart wood marks the period of rest, and as far as assisting growth is concerned, *it is at rest for evermore.* It is through the newer layers or sap-wood, therefore, that the larger portion of the sap ascends, and these in their turn become inclosed by others, and are at last consolidated like the more aged ones into heart wood.

The sap wood is enclosed by the bark, which, like it, is formed in regular layers; though these are much thinner, and cannot be so plainly distinguished. The layers of bark are formed from the interior, so that the oldest ones are on the outside. These are gradually lost, either by decay or by falling off: so that it is seldom that the same number of rings can be traced in the bark as in the wood, although an additional one is formed each year. As the new layer of wood is formed on the outside of the previous one, at the point at which it was in contact with the bark, and as the new layer of bark is added to the inside of the previous one, at the point at which it was in contact with the wood, it is obvious that they are produced at the same spot, and that the newest layers of both will always be in contact with each other.

Between these, always at the close of the season's growth, will be found a glutinous fluid composed of gum and sugar. The gumminess of this fluid is at once perceived by its mucilaginous properties, and that it contains sugar is known by the sweetness of its taste. This is the elaborated sap, ripened and prepared, after the wood growth has been perfected, for being converted into an organized tissue the succeeding year. This substance, called the *cambium layer*, can be readily seen by stripping the bark from almost any twig, in the early part of spring. Later in the season this layer is gradually organized into cells, and from these are formed the ducts and cellular portion of the season's woody layer.

DOES SAP ASCEND.

Fifty years ago, our text-books on vegetable physiology taught us that the sap descended in the fall of the year with as much facility as it ascended in the heat of summer. To prove this theory, the following illustrations were given:—"If a cord be tied tightly around the trunk of an *exogen*, it offers little impediment to the ascent of the sap, but will obstruct its diffusion through the bark in its descent. In consequence, there will be a deficiency of nourishment to the parts beneath, and a superfluity above; so that a protuberance will arise from the stem just at the point where the downward flow of the sap is checked. This protuberance will increase in progress of years (if the tree survive) so as to bury the cord beneath it; but most commonly the tree is destroyed ere long by an insufficient supply of nourishment."

Again: It is in the cells and woody tubes of the *alburnum* (sap wood) that the fluid absorbed by the roots is transmitted to the opposite extremity of the stem, and these cells communicate with those of the leaves, which receive it from them. In the bark the woody tissue has a somewhat different form. Instead of the tubes (cells) lying side by side (as in the sap wood), they branch horizontally from each other, and their function is that of conveying back from the leaves the juices of the plant which have been there elaborated out of the sap brought up by the vessels of the sap wood." Thus they explained the theory called the descent of the sap.

The study of the grand text-book of Nature for the past fifty years has led us to believe that these theories, which we have quoted, have no foundation in fact. We, who are practical horticulturists, have often noticed these large protuberances close to and over the union between the scion and the stalk when we grafted the pear on the quince, the apple on the wild crab and the Heart varieties of the cherry upon the Morello stalk, producing in a few years larger protuberances than a cord would if tied tightly around the trunk of a healthy young exogen. Again, the amount of sap passing through the small cells of the bark must be very small, compared with the amount that passes through the sap wood and cambium layer, in a season favorable to wood growth, when the tree adds one or two inches of solid woody matter to its diameter. Every observant mind who has made this delightful science a close study in the grove or orchard, must have received *ab extra* revelations from Nature, which are not imparted to the scientist in his cabinet, and which the text-books do not nor cannot give.

Permit us to present a few illustrations in support of the theory that the sap does not descend, but is elaborated, retained, spread, ripened and compressed over the entire inner surface of the tree during its upward flow.

In the year 1832 we had charge of a large conservatory for the growth of palms, orchids, cacti, and other tropical plants. In front, planted in a rich, artificial border, outside of the walls, grew twelve grape vines of the Black Hamburg variety, one vine opposite each rafter; age of vines, twenty years; height of stems, three feet. At this point they branched into two limbs, each thirty feet long; one limb of each vine was introduced inside the house

and trained up the rafter early in the month of February; the other limbs were trained upon a trellis outside of the glass roof, up the middle of the sash. The limbs inside, exposed to the regular heat of 70 degrees, soon began to push their buds, expand their leaves, unfold their blossoms, and large bunches of ripening berries hung down from the rafters, while those limbs outside were just beginning to show signs of active life. The ripe clusters were all gathered, the new wood and new buds all ripened and matured, the leaves had performed their functions, and, sere and yellow, were beginning to fall from the vines inside, while the vines on the roof outside were making a vigorous and luxuriant growth. Query: How did the descending sap from the limbs inside flow down that three feet of stem, through which was rushing a resistless *upward* flow of sap towards the vigorous growing limb outside? We saw this experiment repeated for eight years in succession, and yet no protuberance was formed at the junction of the limbs.

In 1839 we superintended a long range of forcing houses for the production of early fruits. The house at the west end of the range was devoted to peach culture. On the wall outside of this structure a large Black-heart cherry tree was trained. The points of the branches next to the house had been introduced between the wall and wall plate, and were trained on the back trellis of the peach house, covering about twelve feet square of surface. The house was closed and the temperature raised to 50 degrees about the middle of January. About the first of February the buds on the portion of the cherry tree inside of the house began to burst. Soon the whole surface was covered with snowy blossoms, while the large tree outside was dormant, the soil in which it grew frozen six inches deep and the ground covered with one foot of snow. In the month of May we were clipping off the large bunches of ripe, luscious fruit, while the tree outside was one mass of bloom. The new shoots on the branches inside had ripened their wood growth, and were as bare of foliage as the trees of the forest in winter, while the parent tree outside was making a vigorous growth. We pause to ask the question: How could the sap descend in the contracted sap vessels of the new bark to the points of the roots in opposition to the upward flow? or how far down the branches when that portion of the tree inside had completed its season's growth?

Again, the house at the east end of that range was set apart for the production of early grapes. On the wall outside of the house a large fig tree was trained. The extreme ends of the shoots had been introduced into the vinery and covered the whole of the trellis on the back wall of the house. In the month of June we were gathering large Brunswick figs, ripe, sweet and delicious, whilst the fruit on the parent tree outside was hard and green. Now, the upward flow of the sap of the fig tree is very abundant and rapid when in vigorous growth. How could the descending sap from these branches inside that were finishing up their season's growth and forming their embryo fruit, pass the resistless flow of the ascending sap in the branches outside?

The cottage homes of England are enshrined in story and in song because of their woodbine-covered porches and jasmine and rose-covered walls. A lady—a true flower lover—living in one of those quaint Elizabethan structures, in a freak of fancy, had introduced under the window sills of a large bay window, leading shoots of the above named plants, training them up and over every available space. At Christmas time, when the "yule log" was burning and the merry "waits" were singing their plaintive carols, this bay window inside was a "thing of beauty and a joy"—one mass of flowers and redolent with perfume, and yet the parent shrubs outside were leafless, shorn of their blossoms, and gone to rest for the winter. Where was the capillary attraction to cause a descent of sap in those portions of the shrubs inside of that bay window?

These illustrations show conclusively, we think, that the doctrine of the "descent of the sap" is a fallacy. To cause an *upward flow*, light moisture and heat are necessary, for if these be excluded, exhalation is entirely prevented. And we conclude that in the case of those portions of the grape vine, cherry, fig and flowering shrubs growing inside of a hot-house and bay window, exposed to these three influences, these caused their buds to swell, unfold leaves and bear flowers and fruit, whilst the trees and shrubs outside, of which they were a part, were in a dormant state. These illustrations also prove that the "flowing sap" begins to move in the upper branches long before the *ascending sap* commences its upward flow from the roots.

Of all the many divisions of natural science, vegetable physiology is of incalculable value to the practical horticulturist. The principal upon which it rests point to every operation within his province, and show him, unerringly, as no other system can, the errors and mistakes of his daily practice; and as the finger-board by the roadside assists the benighted traveller, so does the study of plant life open up new ideas and suggest new modes of culture, based upon truths that cannot be combatted.

The number of horticulturists are too few who today can explain the various functions which roots, stems, leaves and flowers have to perform, or what action or changes take place during the growth of these organs of vegetation; and yet, a perfect knowledge of these principles will render more valuable assistance to the diligent inquirer after truth than all else besides.

Botanical science, unapplied, is of no value whatever to the horticulturists of the Mississippi valley. But this science, applied for practical purposes, is the best science, the only science, that will afford us help in carrying forward the great work in which we are all engaged.

In pursuit of truth, the student must accept of Dame Nature as his teacher. Let him take her by the hand and enter her temple; there he will make the best of her and she of him. They will get on together rarely, she as his ever beneficent mother, he as her mouthpiece, her conscious self, her minister and interpreter.—*Farmers' Review.*

THE common sweet-scented goldenrod (*Solidago odora*) is becoming an article of commerce as a tea. Its use is said to have been begun in Central Pennsylvania some fifty years ago by the Germans. This "Blue Mountain tea" sells in the Chicago market for $1 a pound.—*American Grocer.*

CEYLON VEGETATION.—Mr. M. M. Ballou gives the following description of Ceylon Vegetation in the *American Cultivator* of the 29th ult.:—"The forest and jungle of Ceylon abound in valuable woods. Here we have the Ebony, Satin Wood, and Calamander Trees, the latter the most highly prized of all the cabinet woods, and of which some beautiful samples may be seen in the Escurial, near Madrid. The entire family of the Palm is found in great perfection, as well as fragrant Balsams, tall Ferns, and the singular but valuable Indiarubber tree, with a large share of its twisted roots above ground. The Bamboo, next to the Coconut, the most useful of all trees to the dwellers in the tropics, increases so rapidly here, that by actual measurement it makes 12 inches vertical growth daily, or half an inch per hour. It has even been said that it can be seen to grow, which is almost a fact. The writer saw one group of the Bamboo, less than ninety days old, which exceeded 90 feet in height. Mingled with these woods are fruits and flowers of many varieties. At the north we have distinctive forests of Pine, Cedar, Oak, &c., and our fruits are cultivated in orchards, but tropical verdure and vegetation are more promiscuous. The Breadfruit tree particularly interests one with its deeply serrated feathery leaves and its melon-shaped fruit, weighing when ripe 3 lb. or more. The tree forms a natural food supply to the natives, and three or four trees will nearly support a family, at least keep them from hunger, the trees bearing for nine months of the year and growing to a height of 50 feet. The Palm asserts its predominance everywhere, and next in abundance is the Banana, bending under the weight of the rich yellow fruit, always dominated by the tall Coconuts, with half a ton of constantly ripening nuts in every tufted top. Mingled with these are flower-bearing trees 30 feet in height, including the red Rhododendron and the scarlet-blossomed Cotton tree, while flowers less pretentious catch the eye in all directions among the undergrowth. The sacred Lotus, as thick as Pond Lilies with us, floats upon the shaded pools and perfumes the air." [Who is Mr. Ballou, and how came he to represent the north of Ceylon as possessing a vegetation of pines, cedars, and oaks?—ED.]

Correspondence.

To the Editor of the "Ceylon Observer."

LEAF DISEASE AND THE LIME AND SULPHUR CURE.

Yercaud, Shevaroy Hills, India, 13th Dec 1884.

SIR,—I have lately been reading a book published at your Office, called "The Campaign of 1879 against Coffee Leaf-disease by the Coffee Planters of Ceylon," which is almost entirely composed of extracts from editorials and letters which appeared in the *Ceylon Observer* of that year. This book asserts that Mr. D. Morris discovered a cheap and perfect specific for leaf-disease in the year 1879. His cure was to dust the trees with a mixture composed of 3 parts of caustic coral lime to one part of flowers of sulphur by weight; and it was also recommended that quicklime should be strewed on the ground to disinfect the soil, prunings, fallen leaves, &c. It was claimed that the cure was perfect, and that the cost of the materials in Colombo was less than R20 per acre of 1,200 trees. Can you, or any of your readers, inform me whether this cure is still practised; and, if so, whether it continues to be thoroughly successful; also, if it is not now practised, why it has been abandoned?—for application by the coolies' hands is said to have been tried and found practicable and extremely cheap. One still constantly reads of estates being abandoned in Ceylon on account of leaf-disease, and in your November number, at page 391, you say:—"A fair degree of success rewarded their efforts [Ceylon planters] * * * * until the calamitous advent of the debilitating leaf-disease. Even after its appearance manures were liberally applied, until many planters found that they were merely feeding the fungus." From this one would infer that the vaunted efficacy of the lime and sulphur cure was no greater than that of the numerous specifics which have been tried and found wanting. But I should much like to know all about it, and should be very glad if you or any of your numerous readers could kindly enlighten me.—I am, sir, yours faithfully, ROBERT GOMPERTZ.

[The history of the case is but too simple. The cure *was* effectual in clearing bushes and even estates of the pest. But as it was impossible to apply it simultaneously to all the coffee bushes in the island, the ubiquitous fungus in a few months re-appeared on the estates which had been treated with lime and sulphur and the contest had to be abandoned. All that could be done was done, but the fungus prevailed. And now the most sanguine can but watch and wait.—ED.]

THE CLIMATE OF THE NILGIRIS: PROBABLE CONSEQUENCES OF THE HEAVY YIELD OF TEA IN CEYLON: HOPE FOR COFFEE.

December 16th 1884.

SIR,—With reference to your comment in the December number of your esteemed periodical *re* Mr. Lawson's report on the Nilgiri cinchona plantations, allow me to remark that the occurrence of a killing frost and abnormal season, once in about thirty years, by no means constitute an "unsuitable climate." The climate of the Nilgiris is as suitable for the growth of cinchona as the soil is. With fair treatment canker is almost unknown, at least west of Ootacamund. With only one weeding and forking in the one year old cinchonas seems to get along fairly. Indeed, the cost of upkeep of private cinchona estates on the Nilgiris is being reduced to a very low figure in these hard times. What little cultivation is given is chiefly bestowed upon supplies and young plantings.

No doubt it is very gratifying to our Ceylon brethren to turn out from 800 to 1,000 lb. of made-tea per acre, but I would advise them to make hay while the sun shines; for, at that rate, nature will doubtless square the account in a few years time by calling a halt to enable the exhausted (not impoverished) functions of the tea bushes to recruit. Some one, or more, functions of the tea plant will then be temporarily suspended, which will be the signal for a general out-break of red-spider, &c.

In my humble opinion this was the secret of the disastrous *Hemileia vastatrix*, and, if I am right, your coffee bushes ought, with fair play, to resume their temporarily suspended functional duties, and coffee look up once more in Ceylon. Unlimited yield in a forcing climate cannot continue for an indefinite period of time. Meanwhile, we, poor planters, in more temporate climates, will make shift with our modest three or four hundred lb. per acre, and quietly bide our time which, according to Nature's own law of compensations will surely come.—Yours faithfully,

ONE OF THEM.

P. S.—So far we have scarcely had a single touch of frost yet, but fine, mild, growing weather, which, after last year's abnormal weather, is only another illustration of the law of compensation.

OLD AND NEW LAND FOR TEA.

20th Jan. 1885.

DEAR SIR,—Seeing my letter (page 603) in print, I at once perceived its sins of omission and haste, in that part of it where I refer to partially-neglected land thrown out of the area of regular cultivation. I did not mean that such land should be *wholly* abandoned if planted with tea, but "seemingly" only, as I rather carelessly wrote. Going through it occasionally with quintanies, to keep out "mul shedy," guavas and mana-grass, is a very simple matter compared with heavy weeding. I am trying it on a *small* scale, and see no reason to fear (after 18 months only).

"S."'s strictures, page 633) with the light I afforded him, are justifiable; and I think the man who would do as *he* questions would be "insane"; so, also, would the man be insane who would *wilfully* let his land into weeds. But given a weedy estate, however it became so (O, ghost of "Old Hand"!), it is not wise to keep a larger acreage clean than can be profitably cultivated, as most planters admit and practice. It was of parts of such land (to be seen anywhere upcountry) of which I spoke, and not as "S." insanely suggests that a man should leave it all and go home. Albeit I have an abandoned estate in a certain good tea district, which I should now be extremely glad to find had been well planted with tea five or six years ago! But this *en passant*.

I do not "advise" anyone to be "insane," but land otherwise lying idle, but kept free from jungle growths, might, in many instances, be treated as I suggest, under given circumstances. The idea was suggested to me by an experienced Indian tea planter; and, if I am not misinformed, a certain well-known and well-kept tea estate was in its first year subject to this process, when, before the advent of Mr. Cameron, tea was a doubtful enterprize.

But let "S." look at this question all round. The point in discussion is: *Old land in high districts versus new land in low districts.* "S" either does or does not know all the difference between them in extreme cases. Let me enlighten him. Riding through an old district a short time ago, I saw much old, washed-out land, upon which not a vestige of surface soil remained, planted with tea, and clean as a plate. This is old land at a high elevation. Compare this with newly-cleared forest-land in the lowcountry, its very opposite. The latter should probably revert to impenetrable jungle in one year, if neglected, and therefore *must* be kept clean. The former kind may be seen any day upcountry, after years of neglect, through which a horse might easily be ridden. I know such an estate so planted with tea and so abandoned, that might now be inexpensively re-opened as a tea estate, if the jat were better than it is.

"S." too loses sight of the bearings, which the jibe of spurious "Old Hand" (in your issue of the 15th) should have impressed upon his memory, viz. "hard times," "poor man," "next year," the ghost of "last year," &c, Let him read Mr. Talbot's picture of the state

of the planting community, chiefly of proprietors ; and let him thank God he is only a swell of a superintendent (if such be the case), and not a mortgage-ridden, helpless, hopeless "proprietor." Many, I dare say, envy him his coigne of vantage. But perhaps Mr. Talbot (who seems to have more humanity in him than some of his neighbours) was wrong, and things are not so bad ; and that "Old Hand" of your issue of the 15th is another lucky and successful man, and perhaps he is not. Overdoing it has ruined more men than those of less "energizing" principles. Many an estate has been ruined by over-manuring : for instance, the finest coffee estate I know at this time, 300 acres of one unbroken sheet of luxuriance, gives in these times steady paying crops without a particle of manure ; but if the proprietor insisted upon 6 cwt. an acre, instead of the steady 3 cwt. he now gets, he doubtless would get it at a cost, but to the injury of his estate and future expensive upkeep. I am stating a special case and not speaking generally, only that it is not *always* wise to be a high cultivator, through which many a man has *lost* his estate.

I hope I have answered "S." ? As regards insane advice, there are not many men in the country who dare attempt experiments ; and those who might do so, need not.

But there is still a point left about the uncovered tea plants. The truth is simply as stated by me. During some few fine days in September I burnt off a patch of patana, planted it up with the tea in question, and left it till middle of January. For the last three months or so I have not been able to see these plants buried in weeds and grass. When uncovered they were better grown, and were better preserved than their fellows which had received better treatment. That's the small fact as stated by me, having been led to do so by the statement made in your letters "From the Hills" of tea holding its own even in wholly abandoned land. "S."'s scepticism does not trouble me. I am only amused at his surprise, as *he* evidently does not know half what tea plants can stand. "S." cannot trace any advice here, or even the slightest inference that I intend to practice the operation. His remarks about the coolies is another evidence of his want of observation. It is *not* Ramasamy's mammoty, or scraper, but insects that attack young plants which is about the worst treatment they can stand. You, sir, put the question, "*Does tea require as careful weeding as coffee* ?" My answer, as an "Old Hand" (but with only 18 months' experience of tea), is : "Certainly not," by a very long day. Coffee was always sensitive to old weeds, but now-a-days one season's neglect kills it. But bearing in mind the differences in lands : that in the first vigor of virginity in the *lowcountry* would, I should imagine, quickly encourage such a growth of vegetation, if neglected, as would astonish even tea. If "S." really wants "advice" here it is. Motto : Reduce the area of cultivation to within your means, and keep that clean at all costs. Do what you like with the rest, but if you spy an opening for "experiment," which may outrage your neighbour good Mrs. Grundy, do not be frightened by that old woman from doing yourself and "the State" that "service."

OLD HAND.

AN ENEMY OF THE CACAO PLANT.

Matale, 20th Jan. 1885.

DEAR SIR,—In the enclosed match-box you will find a beetle. I should be much obliged if you could tell me its name, &c. It was found on the branches of a young cacao tree which it (?) had just succeeded in cutting down. The stem where it was cut was about 1¾ inch in diameter. I have seen a good many trees cut down in the same way, but as the stump always sends up a good sucker they will not do very much harm.—Yours truly, ONCIDERES VOMICOSUS?

[Our entomological referee writes :—"A longicorn beetle. In Packard's *Guide to the Study of Insects*, page 498, will be found a description of an American species, *Oncideres cingulatus*, commonly called the girdler. Its habits are thus described :- 'This insect may be seen in Pennsylvania during the two last weeks in August and the first week in September, feeding upon the bark of the tender branches of the young hickories. Both sexes are rather rare, particularly the male, which is rather smaller than the female, but with longer antennæ. The female makes perforations in the branches of the tree upon which she lives (which are from half-an-inch to less than a quarter-of-an-inch thick), in which she deposits her eggs; she then proceeds to gnow a groove of about a tenth-of-an inch wide and deep around the branch and below the place where the eggs are deposited, so that the exterior portion dies and the larva feeds on the dead wood and food which is essential to many insects, although but few have the means of providing it for themselves or their progeny by an instinct so remarkable.—ED.]

TEA-CURING : THE CHALLENGE ROLLER.

Blackstone, 22nd Jan. 1885.

DEAR SIR,—I have frequently been asked what I could say for the "Challenge" roller, regarding the merits of which I refrained from committing myself to an opinion, without previously obtaining a report from the "Lane," on not merely a sample but an ordinary break. The tea having now passed what may well be termed the crucial test, I send you the report for public information, and shall be glad to send you samples made with this machine. It makes, you will find, a bold wiry well-twisted tea. Its principal feature is that its work is done without much breaking, and it brings out the higher grades without damage to the leaf. It can be worked with six coolies, and, if there is not much tea making, even four coolies may, in an emergency, command the machine for a roll or two. It wants no great speed for efficient work, and will roll the tea as I have described above up to 80 lb., withered leaf, in 30 or 35 minutes, according to speed. Where there is not water enough to work a wheel at full power for a "Jackson," the "Challenge" will cause no embarrassment.

It has also this advantage, having handles on, that during a drought, where the water-power is reduced, manual power can be always added, to supply the deficiency. Its one great fault at first was that it either broke or flattened the leaf. It was brought to public notice somewhat prematurely by its sanguine inventor, and the knowledge of this fact was sufficient to discourage men so fastidious about manufacture as the Ceylon planters are from investing in this machine. The burden of perfecting the roller was transferred to the purchaser, who paid about R900 for the privilege. In my own case, experiments with various sized and shaped battens was a matter of almost daily occurrence for some months, till at last I found alterations to suit me. The battens in the one used at Mariawatte were also altered or added to, I understand. The inventor has himself, I see, condemned these first adopted battens. I obtained lately two dozen studs or little cones to replace all but four battens on each cone. But these I do not prefer to the battens at present in use here, as the studs I find only help to tear the leaf up, and are, besides, too many. I mean however to experiment with them and slightly round off the offending points and arrange them in a manner not merely calculated to give satisfactory results but in a manner that careful trials and experiments may justify, or off with them. In the meanwhile, having so far succeeded with the battens which

I am now using, I have no hesitation in saying that tho "Challenge" is a good tea-roller.—Yours truly,

JAS. H. BARBER.

Report and valuation of 21 packages tea per ship "King's Cross" from Colombo :—

Blackstone, Ceylon.—7 half-chests broken pekoe (good strength and flavor, bright blackleafy broken pekoe, good tip), 2s 9d to 2s 10d; 7 half-chests pekoe (fair strength, good flavor, black, rather bold, irregular fairly twisted leaf, few tips), 1s 11d to 2s; 4 half-chests broken souchong (rather strong, brisk flavory, black, rather small, flat, choppy leaf), 11d to 1s; 2 half-chests pekoe fannings (rather good, strength little brisk, small mixed pekoe fannings, rather irregular, little tippy), 1s 6d to 1s 8d; 1 chest dust (rather strong burnt, small black pekoe fannings), 10d to 1s. These teas show fine quality in cup.—LLOYD MATHESON & Co., Brokers.—London, 24th December 1884.

SQUIRRELS AND CACAO.

Passara, 22nd Jan. 1885.

DEAR SIR,—I shall be much obliged if any of your numerous readers (especially any of those who have anything to do with cacao) will give me the benefit of their experience as to the best way of contending with the squirrel pest. Last year I lost fully 20 per cent of a nice little maiden crop through their depredations, and this year they are already beginning to attack the pods, although they (the pods) are not yet more than four or five months old. I tried shooting them last year, but with little or no effect: perhaps I was not persevering enough. Who will come to the assistance of

A POOR CACAO PLANTER?

[In Dumbara, we believe shooting was the only means taken.—ED.]

SOMETHING MORE ABOUT TEA: LARGE FLUSHES AT A HIGH ALTITUDE.

Abbotsford, Lindula, 24th Jan. 1884.

DEAR SIR,—When everything about one's own concerns is so eagerly seized upon, exaggerated, misconstrued, and disbelieved, as it is in this scandal-loving little island of ours, it behoves me to weigh every word set down in the balance of truth, and reject everything that will not stand the test of proof. I therefore say, once for all, that I am prepared to stand by all I have said, or may in future say, to the public through your columns. I know that the most absurd and often wilfully incorrect statements are being industriously circulated, chiefly by those who have never been here and who hardly know a tea-bush when they see it; but so long as this estate tea yields 500 lb. per acre, and averages 1s 3d *all round* (including dust and fannings), we can well afford to smile at the growling of the envious. I give one or two instances of these reports and the faith that can be placed in them.

A few (about twelve altogether) of the smaller seed-bearers, from 6 to 12 feet high, showed symptoms of decay; so I pruned them down. This has been exaggerated into the definite statement that all our giant trees are dying out! I am sorry to say that about a fortnight ago our special giant was blown over by a strong wind, but we have ready to take his place, fully a thousand giants, of which not one is touched by disease. Again, a gentleman asked my conductor (in my absence) how much tea we had sold locally. He told him, "Nearly 7,000 lb." This, I hear, is being spread abroad, but of course in a new shape, namely, that we had sold 7,000 lb. of *red-leaf*. So many in all parts of Ceylon are now practical tasters of Abbotsford pekoe, broken pekoe and pekoe dust, that it is needless to refute the above. Another case will suffice. Among over 500 coolies I have three or four of those eccentric creatures, of which I suppose every estate has one, if a careful enquiry were made: I mean Tamilized Sinhalese, or people who are Sinhalese by race, but have, for some reason, thrown in their lot with Tamil coolies, adopting Tamil names and speaking Tamil. This, I find, has given rise to the wonderful story that we are working a gang of *thirty* Sinhalese *and their wives* as an experiment.

Now for "Moderation"'s very sensible letter, with which I fully agree, but all of whose questions I really cannot answer. For instance, as we are not a public company I do not see why we should tell the world what we have sold locally and how much it costs us to make our tea. The former question I have partly answered above; the latter it is impossible to give satisfactorily on such an estate as this, where a great deal of the expenditure is shared by coffee and cinchona, and unless I could give a perfectly reliable figure I would rather not give one at all. I can only say to "Moderation" what I say to all other disbelievers: "Do come and see for yourself." In passing I would call Mr. Rutherford's attention to a mistake that had better be corrected in the Mariawatte statistics. His acreage of manuring is given as 50, 15 and 40, which make 105 and not 100 acres, so that a 5 too much has crept in, or 5 acres were manured twice. I trust he will not misunderstand my reasons for pointing this out at once. I cannot give "Moderation" our average price for last year, as we do not hear of the sale of December's tea till somewhere about April, but I think I can safely say it will not be under 1s 2d. Our average for 1883 was, as I said, 1s 3d. The decrease (if any) for 1884 is not due to the increase of yield, but to a depreciation in prices all round. As "Moderation," in his reference to Looleecondura, rather infers that a higher yield than 350 lb. per acre, must necessarily *distress* the bushes, I give some figures, that will rather open his eyes, as to what our bushes are doing after giving their 500 lb. last year. Here is this week's work, four days' picking: we had to stop on Thursday as our tea-house got too full :—

Date.	Pluckers.	Green Leaf. lb.	Average lb. per cooly.	
Jan. 19th	176	3,636	20·65	} school children
,, 20th	177	4,552	25·8	} went to school at 2 p.m.
,, 21st	184	6,580	35·7	} school children
,, 24th	172	6,220	36·16	} picked all day.
Total...	709	20,988	29·6	

Fancy 5,250 lb. made tea in four days, and an average per cooly for the week of 29½ lb. leaf! The trees are in splendid condition. The following is a statement of the distribution of the picking for this and last week :—Cattle-shed field, 15 acres, 4,0 8 lb. leaf, 1,002 tea, rate 1,202 lb. per acre. Bungalow field, 5 acres, 1,225 lb. leaf, 308 tea, rate 1,109 lb. per acre. Lower estate, 20 acres, 4,490 leaf, 1,122 tea, rate 1,346 lb. per acre. 70-acre field, 13,678 leaf, 2,420 tea, rate 879 lb. per acre. Of course I do not expect, and hardly desire, such a high rate to continue. To show what Tamil women can do when put to it, yesterday 17 coolies brought over 50 lb. each, four brought over 60 lb., one 70, one 73 and one 75! My books are open to any who choose to examine them. As previously stated, our picking consists of the bud and a leaf and a half, and the above 21,000 lb. was almost the finest sample of leaf I have ever got on Abbotsford.

—Yours truly, A. M. FERGUSON, JR.

THE people of Florida, according to some of their prominent journals, do not want any protective duty on oranges. The growers throughout the State are very hopeful, and declare that when it comes to orange growing, they can hold their own against the world. The next crop, it is claimed, will foot up to about a million boxes.—*Planter and Farmer.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, January 10.

The relative cheapness of sugar has drawn attention to its importance in the raw state for feeding purposes. Germany has taken the lead in this innovation, and France is preparing to follow suit. We have very little exact knowledge as to the action and influence of sugar on the health of stock and the production of milk. It ought to be favorable to the growth of animals and their fatting.

Professor Viollette has, since 30 years, conducted experiments to test the comparative value of beets for sugar production. He alludes to the fact that fashion sometimes leans to one colour, and then to another; thus, from 1850 to 1859, the white-skinned root was alone in favour; from 1860 to 1874, the rose-coloured; now opinion inclines to both. The Professor lays down that the colour has nothing at all to do with the saccharine richness of the root, its purity of juice, or the yield per acre. It is the "flesh" of the root which decides. The best sugar beet has the flesh hard, the skin reddish, the crown very broad, covered with numerous leaves; the root very tapering, penetrating propoundly into the soil, and not protruding out of it. The tapering, deep-striking root not only produces the richest juice, but the latter is especially pure. But such a root requires land very rich, deeply prepared, well supplied with humus, and suitable manures.

The yield of beet has this year suffered in France from the presence of *nematodes*, insects of an eel-like character, about the 3-10ths of the thousandth part of an inch in size; they attack the rootlets, and, having pierced the skin, fix their suckers and live on the sap. In time a small sac or bulb appears, of a lemon shape, filled with eggs, and these bulbs are so numerous as to resemble a row of beads. The parasites have been found attached to the rootlets at the depth of 39 inches. When the crop is attacked, the leaves of the beet fade, grow yellow, and seem pricked with red spots, which soon become black and fall on the soil; this explains why in September the field displays bald patches, as if the wire worm had been at work. Changing the culture, allowing the field to lie in fallow, or dosing the soil with sulphuret of carbon, has been found efficacious. The disease, though only known in France this year, has been recognized in Germany and Belgium since some time. The parasite is difficult to extirpate, as it exists without difficulty on wild mustard, cabbage, and indeed all cruciferæ.

Crows dislike the smell of gunpowder; they are a nuisance at seed-time, and many means have been adopted to get rid of them. John Knox affirmed that the best way to get rid of rooks was to destroy their nests, say in the month of May. A farmer at Brie has invented a *mitraillense* to frighten away crows from some fields; it costs 100 fr., and is worked by a cistern of water and a watering cock, which, on a see-saw principle, raises at fixed intervals a hammer which falls on an anvil, fed with detonating powder, and so produces a succession of explosions.

STRAWBERRY CULTURE IN INDIA.

HINTS AND SUGGESTIONS BY AN EXPERT.

(*Reprinted from the "Times of India."*)

It is generally supposed that the Strawberry cannot be cultivated in India; some say it may succeed in the hills but not in the plains, and decidedly not in the Concan. The matter is, however, now placed beyond dispute by the success of the recent experiment as the Thana Jail Gardens under the able superintendence of Mr. S. S. Smith. That the climate of places, under the influence of the tropical monsoons and heavy rains, is not so suitable for the Strawberry plant as the temperate zone and places beyond such influence, must be admitted. But everywhere, even in Britain, the improved species require the care and experience of a skilled gardener. It is therefore necessary that any amateur or native gardener, before he can hope to attain success, should study and make himself acquainted with the routine of his culture generally, its specialities and requirements, in this climate in particular; and when these are acquired, and put into practice with diligence and perseverance, his labour will be amply rewarded.

It is necessary, in the first place, to guard against water lodging in the parts technically termed the "eye," "crown," and "head" by gardeners. The eye is the centre of the bud, and it is when the bud is opening to develope the flowering and fruiting parts that the plant is most sensitive to injury from water. The crown is the nest of buds, and their seat or foundation, from which the roots descend; the head constitutes the whole of the plant above ground, including foliage, &c. It has no body; hence the necessity of raised and rounded beds and of keeping the plants well above the ground. Soil of a close texture or nature, and consolidation in planting, are also essential requirements.

Botanically, the plant is thus described:—"Fragaria Strawberry, Natural order Rosaceæ, Tribe Dryadeæ, Linnean arrangement, Icosandria Polygnia, Class XII, Order 3, Herbaceous evergreen, perennial. Fragaria, from fragrans, perfumed fruit. This fruit is universally grateful, alone, or with cream, sugar or wine; and has the property so valuable for acid stomachs, of not undergoing the acetous fermentation. The strawberry is not only a valuable and easily cultivated outdoor fruit, but forces well, and with a little trouble in choosing a succession of sorts, they may be had at the dessert every month of the year, though during the three winter months they are without flavour. In cultivating the Strawberry an open situation and rich loamy soil, rather strong, is required for most varieties; and from their large mass of foliage and flowers, they must, till the fruit is set, have copious supplies of water. The row culture is most convenient, and frequent renewal insures vigorous plants and large fruit."—*London's Encyclopedia of Plants.*

Three species come from hot climates, viz., Surinam, Chili, S. A., and India. The Indian species is ornamental, bearing yellow flowers. The successful culture of these foreign species in England, and the well known fact of the Strawberry forcing well, are sufficient data for any professionally trained gardener to act upon; and the additional data, herein given, are conclusive as to its culture in India.

The piece of ground selected for the Strawberry bed should be dug two or three spits (2′ or 3′) deep, and well-rotted manure should be incorporated throughout. The best time for this operation in India is during a break in the rains, but there is no objection to any other time. If water is at command, to soften the ground, it will facilitate the work, if done in the dry season. As soon as the rains are over, the beds should be prepared (if this has not been previously done), and formed thus—3′ wide for three rows, 4½′ for four rows, and 6′ for five rows (which is the most suitable width on flat ground), as may be convenient or decided upon with reference to the amount of rainfall and the nature of the soil as regards irrigation and surface drainage. The alleys between the beds may be 18″ wide, and 2″, 3″, or 4″ deep, in relation to width of beds, respectively, or may be contracted, if desirable, to 15″ or 12″, and deepened proportionately. The beds may be of any length required; in form convex or raised slightly in the centre by the soil from the alleys, that water may not lodge on them in the rains; the plants should be 18″ apart longitudinally and should be planted diagonally crosswise, and consolidated in planting, and the surface of the bed should be firmed and smoothed with a rake. Water with a rose watering-can or pot, irrigate by filling the alleys, drain in the rains, by removing the bay or bunds at the ends of them, sprinkle the plants every evening during their growth in fine weather, but discontinue this as soon as the flowers appear.

Protectors or Guards will now be essential to prevent depredation; birds, flying-foxes, vermin and thieves, being numerous by day and by night. Protectors are procurable ready made at home, but here they would have to be made. This can be done easily when or where octagonal wire netting of ½″ or ¾″ mesh is procurable. Hoops or iron rods or split bamboos bowed over and fastened into the ground, and running rods, or small wire, tied lengthways, will complete the framework to which the netting may be fastened. Over this again, shading material, such as canvas, unbleached longcloth or tiffany may be strained and tied, to protect the fruit from excessive sun heat for 8 or 9 hours daily, and removed at night also to allow the plants the benefit of a couple of hours sunshine, morning and evening. This is very beneficial, and during the rains will protect the growing plants from heavy down-

pours by running off the water into the alleys. A closely-woven fabric is used for this double purpose; the young stock are benefited, and the older ones saved for a second crop.

When the fruiting season is over in May, the runners will soon appear, and advantage should be taken of the remaining fine weather to get them layered, or it will have to be done in the rains. Delay engenders loss in size or weight of fruit, in other words, loss of capital, nor can this by any possibility be made good. Lose no time in getting small 3" size pots ready filled with fine earth, previously prepared; fill, consolidate, and strike off surplus soil with a straight round stick; plunge them in the beds rim-deep, between, not too near the old plants; and when the young plant is formed on the end of each runner, place it on the pot, and upon the runner a pebble stone, the size of a hen or duck's egg, to retain it in position. If a runner appears from the young plant, which is usual, pinch it off. When the pot is filled with roots, cut the runner and remove the plant, shift or re-pot into a size larger, pot firmly, keeping the eye (which is not yet a bud) above the rim level of the pot. Collect all the plants thus layered and potted into a bed in any open place and cover with canvas (as before recommended) to shelter them from heavy rains, to remain until the rains are over and the new beds ready for planting them out.

This is the best way to grow the young plants, and the system adopted by gardeners at home for forcing. Instead of planting out, they are re-potted into 7" pots for fruiting in.

There is also another way which is more generally adopted for transplanting into beds in England; but the climate is much more suitable for it there than here, and skilled labour is also obtainable, and, as a rule, garden labourers are permanent hands.

If pots are not provided, or cannot be obtained, it will become a matter of necessity to adopt it here also. In that case the runners must be left to root in the ground. The prudent and careful cultivator will select the strongest, to the number required, and destroy the rest, to economize the strength of the old plant, and make room for the young progeny to thrive in. The careless and imprudent gardener will leave the runners to become an entangled mass, and when the time comes for planting, he must put up with weakly spindlings that cannot be separated from one another without being torn to pieces, root and leaves; and if the old plants should be alive, they will be completely exhausted, failure or disappointment will follow, and the climate be unjustly made to bear the blame. I have neither sympathy nor advice to bestow upon him, but will return to my wiser and more hopeful reader. By him, new beds have been prepared as directed, and as soon as the rains are over, the young plants will be carefully taken up under his own superintendence, if possible, or entrusted to some one who understands the work, and may be depended upon to see it properly done. Success depends upon the skill of the workman and upon care being taken not to injure the roots in the operation of transplanting. Consolidation and finishing off neatly, will also be attended to. A few days' shading may be necessary if the plants flag; and its continuance for a month afforded if found necessary. The old plants should now receive their final cleaning and trimming, bad leaves and any remaining runners being removed, vacancies filled, the beds neatly dressed, and the alleys dug or loosened with the fork, to facilitate the penetration of irrigation water into the beds, during the coming dry season; and should the alleys become too consolidated at any time for free percolation, this operation may be repeated with beneficial effect.

During the rains, the protectors and canvas will remain in position to benefit the old and young plants equally. Ventilation must, however, be considered; a close, warm, moist atmosphere engenders rapid growth; ventilation strengthens and consolidates; and rest matures. At times, when the moisture of the air is excessive, the canvas will be of use. Our study now is to assist, or rather not to impede, ventilation, but at the same time to secure both objects. This may be done partially by raising the netting and canvas together (the former to support the latter) at the sides, by means of short stakes, or pegs strained and tied in, tent fashion. This may be increased, when rain is not falling for intervals of 12 hours or more, by untying the canvas at the sides and closing or folding it up towards the centre (rollers facilitate this admirably on a large scale), and replacing it when the rain comes on again. A little mild rain will not hurt the plants if the water does not accumulate on or about them. An outburst of sunshine in full power upon the plants, when wet, is very liable to scorch them; this is very injurious and should, if possible, be avoided. The plants being in growth, the leaves are young and tender. To this cause in conjunction with water in the eye, the loss of plants, in their second stage, during the rains, may be often assigned.

About the middle, or towards the end, of October, the canvas may be removed altogether until it is again required in March. The wire netting may be useful if the garden is not fenced or enclosed in by protecting the plants from animals, goats especially, which stray in to browse or feed. If so required, the netting may be retained to save the plants from being eaten or damaged in this way.

All the old plants that weather the stormy season and stand over, may be depended upon to produce a large crop of fruit; but they will not pay for the trouble of again keeping over in this country. The annual and biennial systems alone can be relied upon, and this may be considered settled by past experience.

It is customary at home to lay straw between the plants when the flowers appear, to keep the fruit clean; it will be beneficial here also to keep them cool as well, or straw may be dispensed with. It checks evaporation. If used, it should be laid as thin as possible.

Of soils it may be said, and rightly so, that the Strawberry will grow and do well in any rich garden mould, but there is no mistaking its preference for a stiff, heavy, friable loam, or what may be termed, clay minus its plasticity, and incapable of becoming waterlogged in its natural condition, or rendered so by artificial under-drainage. One of the most striking instances that came under my observation at home, was that of a piece of old meadow land of this kind of soil, which was broken up by trenching two spits deep, the upper or turf spit being thrown into the bottom of the trench, and the under-soil on the top of it; in this state it was left to be pulverized by the spring frosts, &c., until August, when a little manure was incorporated by digging with the fork, and then it was planted in the usual way. Four crops in four years were the result, and the fruit produced was of immense size. Alluvial soil is also very good indeed. The desideratum, therefore, is a heavy friable soil of a close or somewhat compact nature, deep and well drained beneath. Stagnancy and water laying about the plants and getting into the buds must be prevented.

The application of manure water is very beneficial and effective, especially in the older stage or second year. Where stable or farm yard drainage is not economized by liquid manure tanks, the usual method adopted is to put a tokree (basket) full of fresh cow-dung into a hogshead cask of water, stir and let it stand three days before use; if turbid at any time, a little fresh lime will rectify it; other fresh manures may be liquidized and used in this way. The following compounds are invaluable in several ways:—Soot, pure, ¾; Lime, fresh, ½; from 1 to 4 gallons as per strength required, to 1 hogshead of water; mix and let it settle. Water occasionally once per week, or twice in three weeks, copiously; its effect is stimulative. It prevents snails, slugs, caterpillars, grubs, worms, millipedes, white ants, &c., and gets rid of them. Syringing or sprinkling the leaves occasionally, will cleanse them from, and keep away insects. It is largely used by gardeners for this purpose in a general way when plants are in growth, but discontinued when they are in flower, and upon tender, soft, or thin-skinned fruits. Tobacco water obtained from the factory press, hubble-bubble (chilum), or by boiling tobacco, and diluted, will kill aphides and all the fly species that infest plants. It is also used in mixture with the former, and applied with the syringe. Tobacco smoke, in confinement, as used at home, in glass houses, has the same effect. A little sulphur flour, mixed with soapy water or soap-suds, will eradicate mealy bug, scale, red spider, &c., if used frequently, until they disappear. This is also a cure for fungoidal blights, mildew, and the grape vine disease. The sulphur

should be increased to one ounce per gallon of liquid as a strong solution; apply with the syringe or engine very early in the morning; the sun will disengage the fumes perceptibly to the nasal organs. The fumes are given off at about 90° Fahrenheit's scale, when the blight is killed. A combination of soot and lime liquid is still more effective. The Strawberry is subject to mildew. Phosphor in paste, spread upon thinly sliced bread or chupaties, cut into bits, strewed about, and placed in the runs and haunts of rats, mice, and other vermin, will soon rid the place of them.

I was very successful in the culture of the Strawberry many years ago in the plains of the Punjab.

When I took charge of my work there, a quantity of plants were pointed out to me in a piece of ground prepared in ridges and furrows; the object having been to plant on the sides of the ridges facing northward. The work had been done very badly, the plants were much too low in the furrows in many instances, and were liable to be swamped and covered with water by irrigation. Many were dead, others dying, those planted above the water line being alive. My opinion and intentions were solicited and given; but the idea of raised beds in India was laughed at. Though every conceivable site and system of culture, under the shade of trees and in the open, had been tried, and tried without success, yet this new idea was set down as madness. Although discouraged, I hopefully set to work and secured the remnant of the plants by potting them. and until they had recovered, placing them in a shady situation. Beds were prepared, and planting followed in due course. The sequel was very gratifying to me, and the result of my first attempt at the culture of the Strawberry in this country was a marked success. I had the pleasure of gathering, upon an average, about a lb. of fruit per day for six weeks, more or less, and within six months from the time I had taken the matter in hand. The hot winds came on, and dust-storms also, sometimes accompained with rain and hail, and followed by excessive heat. The plants suffered severly in June and July, and many died in August, during the rains. Those plants, however, which had been grown in the shade afforded by some young guava and orange trees, not only survived but produced runners freely, from which I obtained sufficient young stock to double the quantity the following season. From this observation, I adopted shading and protection from the rains, afterwards, to advantage. My stock was again doubled in quantity the third season with a large number of young plants to spare. I was not, however, so successful in securing the ripe fruit. Wire netting was not available or procurable in the Punjab for making protectors at that time (1864 to 1867). I had felt the want of it previously as a protection against ordinary depredators, but in three years the Punjabis had acquired something beyond a taste for this fruit, amounting to a passion, for as soon as the red tint appeared and the fruit was barely three parts grown, everyone disappeared without being allowed to ripen.

In the hill stations, there is no difficulty in growing Strawberry plants, but the proper routine of cultivation is not observed, nor any care taken with them. When planted, fruit may be gathered from them the following season in April or May; afterwards, being neglected, they run into a wild mass, and deterioration follows.

From the foregoing it will be seen that the Strawberry is not a lasting plant anywhere; and to secure fine produce and good crops, it needs renewal annually or biennially in this country, and if this is neglected it will deteriorate. From a business point of view, its culture is very remunerative as was abundantly shown by Mr. Smith's experiment at Thana. He also grows it there as an ornamental plant, in flower beds.

CULTIVATION OF THE KOLA NUT.

To Sierra Leone, so far as we are aware, belongs the credit of having started the first organised scheme for the cultivation of the kola nut on a commercial scale. Plants have been sent to Ceylon and Southern India by Mr. T. Christy, and introduced into the public gardens in India and Ceylon, and here and there private growers are making experiments with them, but we feel sure that we shall be within the mark if we say that it would be impossible to find so much as an acre regularly planted up with this product in either of the countries named. There are, of course, obvious and sufficient reasons for this, and also for the fact that Sierra Leone should lead the van, because the tree is indigenous to the forests of that colony, and there is already a trade in the nut there. We are not surprised, therefore, to learn from one of the local papers that an effort is being made to form a Joint Stock Company, under the title of the "Kola Nut Planting and Trading Company," with the object of cultivating an estate of about 300 acres, and those on the spot who are well able to judge speak of the prospects of the enterprise as very encouraging. For our part we have not yet seen any reliable data as to the cost of creating and working such an estate, nor any estimate of the probable returns, but from what we have recently learned regarding the valuable dietetic properties of kola nut, we have no doubt that there is an important future before it. The main fact in this connection is that Mr. T. Christy has discovered a method of so treating the kola nut as to render it a most valuable food product, and an agent for improving the flavour of cocoa. For the present the process is kept secret, but we are informed that the practical effect of adding even a small quantity of the prepared kola nut cake to inferior cocoa, is to render its flavour in the cup equal to that of the best quality. If this be so, it is needless to say that with the growing consumption of cocoa all over the world, there is a very large field for the kola nut even in this way. There is, however, one thing which will, we fear, militate somewhat against its cultivation by European planters. We are told that it is not until the fifth year after planting that the tree comes into bearing, and, therefore, it will not suit everyone to invest in it on an extensive scale.—*Planters' Gazette.*

THE ADULTERATION OF TEA, COFFEE AND COCOA.

A chemical lecture was delivered on Friday, the 5th inst., in the Hygienic Laboratory of the Health Exhibition at South Kensington, on "Adulteration of Common Food." Mr. Cassall in his opening remarks stated that the subject of the adulteration of food was an extremely wide one. The meaning of the word "food" was more extended in hygienic than in common language, as it included alcohol and tobacco. In defining the word "adulteration" a distinction must be made between it and impurity. There might be impurities present in food which the manufacturer could not help to a certain extent, and in regard to some food a certain amount of impurity was permitted. Adulteration he defined as the addition of some substance to the food which would enable it to be sold at more profit to the seller than by selling it in its pure state. The articles used in adulteration might be deleterious to health, or not. Deleterious adulteration was a very serious offence, although it was not so regarded by those who administered the law. In consequence of the passing of the Adulteration Act, adulteration had very much lessened in this country, and therefore the Act had done a great deal of good. Referring to tea the lecturer said this used to be very considerably adulterated with leaves other than tea, and with sand which had been put on the leaves. It also used to be a practice to cover tea-leaves with prussian blue to give it a more pleasant appearance. That was especially the case with green teas. The Chinese themselves were very clever at adulteration, the most common being what was known as "lye tea." That was made by steeping the leaves in gum, and then rolling them in a heavy sort of sand. The detection of that, however, was very easy, for if some of the tea were boiled, it would dissolve, and the sand, of course, would be found in the vessel. Another form of adulteration was the use of exhausted leaves, which practice seemed to have come in again in this country. Some persons would buy excessively cheap teas, and they got exhausted leaves which were dried and sold again. That was very easily detected by the naked eye. Then, again, tea was adulterated by the presence of leaves other than tea, such as the leaf of the willow. That, however, could also be detected by observing the special character of the original tea-leaf, the veins of which turned up in a peculiar manner. Referring next

to coffee, he said that that was a substance which had been subjected to all kinds of adulteration; and in Paris at the present time, where they were more backward with regard to adulteration than in England, they had recently found coffee adulterated with baked horse's liver, which was once discovered in this country. The adulteration with chicory was the chief thing in use in this country A small quantity of chicory was not objectionable, but when pure chicory was sold instead of coffee, it was. The presence of chicory could easily be detected by means of a microscope, or by putting it in a glass vessel. By means of the latter method the coffee would float and the chicory would sink to the bottom, and as it sank it would cover the water with a deep brown colour. Another test was to press the coffee firmly together in the hand, and if it stuck together and did not fall apart it was likely to contain a large quantity of chicory. Among other substances used in the adulteration of coffee were roasted corn and acorns, which might also be detected by the use of the microscope. Speaking of cocoa adulteration, Mr. Cassal said the homœopathic cocoas were very well named, as they contained the smallest quantity of cocoa. Chocolate, which was made from cocoa, was frequently adulterated with fat; more particularly was that so with regard to the cups of cocoa supplied at cafés. The fat was worked up with cocoa to give it more body.—*Home and Colonial Mail.*

TEA YIELD AND AVERAGES.

To the Editor "Times of Ceylon."

Sir,—Referring to the numerous letters appearing lately in the "Times," *re* tea, I beg to offer some figures showing the difference *in my opinion*, between a moderate yield with high averages and a high yield with moderate averages. I will take an estate as representing in each case 100 acres.

Moderate yield with high average.

Upkeep of 100 acres, including supervision and all expenses, except plucking, manufacture, &c., at R75 per acre	R7,500
Plucking, making, boxing, and all expenses of landing tea in Colombo on a yield of 400 lb. per acre, 40,000 lb. at 25 cts.	10,000
Total cost of tea landed in Colombo	R17,500
Sale of 40,000 lb. at 90 cts. in Colombo.. ..	36,000
Profit on 100 acres.. ..	R18,500

Vs.

High yield with moderate average.

Upkeep of 100 acres, including supervision and all expenses, except plucking, manufacture, &c., at R75 per acre	R7,500
Plucking, making, boxing, and all expenses of landing tea in Colombo on a yield of 800 lb. per acre, 80,000 lb. at 20 cts.	16,000
Total cost of tea landed in Colombo ...	R23,500
Sale of 80,000 lb. at 60 cts. in Colombo ...	48,000
Profit on 100 acres ...	R24,500

That a high average is not incompatible with a high yield has been proved by the Manager of Gallebodde. I was glad to see Mr. Hay giving "Tom and Dick" a rap over the knuckles, as careful plucking cannot be done at much under 3 cts. per lb. taking the year all round. If everyone went in for making, and succeeded in making teas which would fetch an average of 1s 9d in the London market, do *you* think the market would absorb it? *I* doubt it.

Jan. 25th. R.

P.S.—The figures for cost of tea landed in Colombo are not theoretical.

COKE FOR TEA PURPOSES AND FOR DRYING CARDAMOMS.

Mr. Horsfall writes:—"Referring to Mr. Monk's note on page 635, I found that the evaporator would burn coke very well, but I did not get up a temperature of over 150 degrees F., over the furnace with it, being warned by Mr. Monk that if the coke was allowed to get beyond a red-heat it would produce clinker immediately and burn away the fire bars. Doubtless, however, if this is or can be provided for in the construction of the grate, any amount of heat might be got from coke, or at all events sufficient to dry tea with. Regarding my experiment with cardamoms, I cannot say anything conclusive as to the merits of the evaporator. A very slow process at a low temperature is required to prevent this fruit from splitting, and when it is sent down green from the estates the great object is to arrest ripening immediately; to affect this some people plunge the fruit into hot-water and then give it a two-hours' sunning preparatory to aught else, and I can imagine that the evaporator might be of use in estates at this stage when gathering took place in rainy or cloudy weather. I send you a sample of the cardamoms operated on." The cardamoms look very nice, indeed, but taste as if they could bear further drying.

INDIGENOUS ASSAM TEA AT A VERY HIGH ELEVATION.—The *South Indian Planters' Review* states:—"So far back as 1861, we sent to Assam in a Wardian case, a quantity of the finest Nilgiri seed coffee, and got in return in the same case filled with indigenous Assam tea seed, the very first ever imported to these hills, and though planted at the very great elevation of 7,000 feet which gave, with liberal treatment, upwards of 400 lb., of tea to the acre." We have recently heard of indigenous tea growing well at over 5,000 feet in Ceylon, so that our experience of indigenous growing slowly at a high elevation in Dimbula must have been exceptional. Still pure indigenous is stated to be more delicate than good hybrid.

A REMEDY FOR PHYLLOXERA.—Not only colonial wine growers, but tropical planters who have been long struggling hopelessly with leaf disease in coffee, cankering cinchona and other more or less mysterious enemies of vegetable life, will be interested to learn that a medical man in the department of Maine et Loire, France, is reported to have discovered a means of overcoming the phylloxera by an easy and inexpensive treatment, the basis of which is an arsenical solution mixed with cinders. The limited experiments made with this preparation seem to have been attended with admirable results. A vineyard selected from a neighbourhood completely devastated by the phylloxera, and subjected to the new treatment, resisted the scourge in a most striking manner. Not only the foliage and stocks, but the roots remained perfectly intact, while the fruit is said to have been abundant and of excellent quality. Further experiments on a larger scale are about to be made in the Médoc; and the inventor having patented his remedy, the result obtained will receive all possible publicity. The outcome of these experiments, which are being conducted under the patronage of M. Lalande, president of the Bordeaux Chamber of Commence, is awaited with the greatest impatience.—*Planters' Gazette.*

JOHORE.—We are having a good deal of wet weather now, the afternoons being as showery as an English April, and no doubt it is just what the planters call "planting weather." The coffee plantations on the Tebrau Road are looking wonderfully well; one owned by a Malay resident being particularly so; his trees are pronounced by good judges to be some of the finest grown in Johore. I am told no manure has been given them, with the exception of a little burnt earth. The secret of their healthy state, I believe, consists in the fact that each plant was put into a very deep and wide hole, filled in with the best surface soil, and afterwards *nursed* in every sense of the word. In amateur planting, this method may do very well, but I doubt if it would pay on a large estate. I have received information of the capture of the crocodile that killed Mr. Larken's coolie. It has been caught with a hook baited with a fowl, and proves to be a monster measuring 14 feet 3 inches in length, and so heavy that 12 men could hardly carry it up from the river to the house. I am informed on good authority that Syed Mohamed Al-Sagoff is about to take up a thousand acres in Muar for planting purposes, and to purchase several blocks of land in Bandar Maharanee to build shop-houses. His example will, no doubt, be followed by other monied Arabs.—*Singapore Free Press.*

THE RICE TRADE.—The volume of business in rice is greatly increased over previous years, due to a growing appreciation in this country of the merits of rice as a food product. "You may not know," said Mr. John Talmage, of Messrs. Dan Talmage's Sons & Co., "that it is the leading food of the world. In quantity, its production exceeds that of all other grains combined, and what is, perhaps, more surprising, more than half the population of the world make it the prominent part of their diet. No other cereal, nor even potatoes, can compare with it. It is *the* staff of life. The quality of the crop this year is far below the usual average. The harvest storms greatly injured it in this respect. Much of the outturn has been of yellow or mowburnt, which, while not injuring its value for food, damages it many per cent commercially. East India rice does not materially interfere with domestic. Our producers do not, or at any rate ought not to, complain, when they are protected from the East India by a duty on the latter of 2¼ cents per pound, or on the bond value of from 75 to 100 per cent.* The East India in a measure, of course, tends to regulate the prices of the domestic, as the former is within a week to ten days' reach. During the early part of the crop, up, say, until the first of the year, prices on the home product generally fall below any competing foreign, and thus excludes them temporarily from the market. The East India stands the United States in good stead, and its use is steadily increasing. Our annual imports now run from two to three hundred thousand bags of two cwt. each."—*American Grocer.*

NATAL LABOUR SUPPLY AND PLANTING.—The statements made at the last meeting of the Victoria Planters' Association in regard to the labour supply of the colony would, at certain critical moments in our industrial history, have been hailed as tidings of great joy, and as the announcement of a new dispensation. "Any amount of labour," said Mr. Binns, one of the county's representatives, would be forthcoming in a short time. True that labour is coolie labour, but as coolie labour is admitted by all coast planters to be the one thing needful, such a declaration on the part of the Chairman of the Indian Immigration Board is obviously a fact of the most cheering nature, and of the most substantial importance. But this was not all. The Association was told that Mr. Orton has organised a labour agency with the East Coast districts north of Delagoa Bay, which has already succeeded in bringing 2,000 hands into the colony. These men have been greedily taken up by the railway contractors, at rates of wages varying from 40s. to 25s. per month, but as the railway works are now near completion, these people will be available at so low a rate of wages as 10s. per month. It was admitted that the competitive influence of the African labourers had brought down the rate of wages paid to "free"—that is unindentured—coolies from 25s. to 20s. per month. There is thus every prospect of an ample supply of low-priced coloured labour during the immediate future. Such an experience is probably unknown at this moment to any other British colony where tropical agriculture is going on. Unfortunately it comes to us at a time when the ruinously low prices of sugar render the very existence of the sugar industry a matter open to doubt. But may it not be possible to utilise these large opportunities of cheap labour supply in other ways? Cannot new industries take advantage of the golden chance? An affirmative answer might be forthcoming were our political condition and prospects other than they are. But not the least depressing feature of the existing crisis in South African destinies—indeed the gravest feature—is the paralysing effect produced upon investment and enterprise. Both in Natal and in England, the uncertainty that prevails tends to repress the energies of colonists and to discourage the confidence of capitalists. What with cheap and plentiful labour, and fine seasons, there might be a reasonable expectancy of large development and quickened activity in the prosecution of colonial industries and the opening out of colonial resources, but the confusion that prevails acts as a blight upon effort and enterprise. This view of the position cannot be too seriously considered by all who have a stake in the progress of the colony.—*Natal Mercury.*

* What would our American cousins say if England were guilty of the wickedness of imposing a duty of 100 per cent on their wheat?—ED.

MR. JOHN HUGHES, THE EMINENT CHEMIST, ON TEA IN CEYLON.—Mr. Hughes, in a letter to us writes:—"I am glad to hear tea is progressing so favourably, but I agree in thinking it most unwise to pull up good coffee trees to make a tea garden. If a change is desired, why not do so *gradually*, planting tea between the coffee, and thus protect the land from exposure to tropical heat and wash? After my analyses of the Indian cinchona soils, which were so rich in nitrogen, I feared your Ceylon soils would not do generally for cinchona, being too poor in organic nitrogenous matter. But for tea I have every hope, and my friends in Mincing Lane now speak most favourably, very different from what I heard in 1878 on my return from Ceylon, when planters had but little experience in preparing tea."

SUGAR PLANTATIONS IN NORTHERN QUEENSLAND.—From more than one recent visitor to the Lower Burdekin we learn that Seaforth is the cleanest and best cultivated plantation in the North, and that the proprietor being always able to procure fresh water at a depth of ten feet the cane fields can be easily irrigated if necessary. The crushing about closed has been most successful, and it is a pity that such sparkling sugars as those exported from Seaforth and Calamia this season have been subject to such a fall in price. We are also informed that the best collection of agricultural implements are to be seen at Seaforth. The "Pioneer" mill, made by A. & W. Smith, made 950 tons of sugar in 80 days! "Hands all round!"—*Tropical Planter.* [Scaforth is the property of Mr. Mackenzie, formerly a tea planter in Coorg.—ED.]

SUGAR PROSPECTS.—The prospects of the European beet crop as a whole continue good, and there is a probability of the total yield exceeding the immense one of 1883-84. With the enormous stocks in store in Europe and America, the chances favour a still further fall. There are on every side bitter complaints that the old-fashioned sorts of cane sugar and all kinds of beet sugar at the present prices yield a loss to the producer. Vacuum pan cane sugar on some estates still yields a profit, but the West Indian planters mainly still use open pans. They have, however, let so many years pass by, although what was coming upon them was perfectly obvious to the rest of the world, that their difficulty will no doubt be immense in finding the capital necessary for the improvements, which are essential if they are to continue to make sugar. The position of these colonies in which sugar has been the staple industry is critical. British Guiana, the most enterprising sugar-producing colony, is feeling the present crisis very acutely. Planters have had to cut down expenses to the lowest point, and even then the profits on sugar have been next to nothing. In the Islands the same cry is heard. The depression in produce affects the mercantile community and trade throughout the West Indies is extremely dull while rumour is busy with reports as to the position of firms who have hitherto been considered financially strong. The depression extends far beyond the West Indian Islands. Complaints have been heard from the Queensland sugar plantations. Mauritius has been a sufferer with the rest, and the state of the sugar industry there has been a chief cause of the failure of the Oriental Bank. All that has happened in this respect has been foreseen for some time past. Ten years ago when the duty on sugar was taken off, the prophecy was freely hazarded that sugar would before long become a drug in the market. The event has been not quite as disastrous as this for the sugar industry. Sugar has not fallen to a price which allows of its being used for manure, as it was declared it would be. But we have only too certain evidence that the cultivation of sugar is no longer as remunerative as it used to be, and as, in a very intelligible sense of the words, it ought to be. The main cause is not far to seek. There are too many hands employed upon it, and too much money has been sunk to obtain an adequate return. In such a state of things there is all the more reason that the sugar producers should have fair play.—*Home and Colonial Mail.*

TEA CULTIVATION AND YIELD AT HIGH AND MEDIUM ELEVATIONS IN CEYLON. No. I.

COFFEE WHICH STILL YIELDS PAYING CROPS—CINCHONA BARK KEEPING UP OLD COFFEE.

The annual and weekly reviews of a number of London Tea broking houses are to hand by the mail, and the series of sales reported, including the really magnificent prices for Rookwood teas, are very satisfactory. Several of the London Firms call attention to our summing-up and review of 4th ultimo, in which we deprecated too great haste on the part of planters to transform all their coffee acreage into tea—and indeed too great haste on the of any individual proprietor to plant more than a reasonable extent with the now leading product. We wrote in the interests of careful planting and careful selection of seed, as much as of retaining intact coffee fields that still paid for expenditure if not some interest on capital. To cover the country again with the one plant will be too much like repeating the mistake at first committed with coffee; so we shall trust to see tea, cinchona and even coffee fairly distributed up-country, with in many cases, cardamoms, and cacao and even *coca* with the half-a-dozen minor similar products.

Our friend and correspondent "Moderation" (see p. 609) has done good service to the cause of the tea enterprise in Ceylon by the suspicions he ventured to express and the questions he asked of the planting community. Mr. Drummond of Western Dolosbage, without dealing with a thousand of pounds per acre, or even half that maximum, gives good reason we think in his statistics of the yield from very young tea, for regarding his district favourably; and we have no doubt that a proportionably encouraging report can be given by planters in old Dolosbagie. Travelling the other day in the company of planters so experienced and shrewdly observant as Messrs. Elphinstone, Talbot and Borron we had the opportunity of hearing a good deal on the *pro's* and *con's* of new and old products and also of the advantages and disadvantages of certain tea machinery. Mr. Borron had doubts as to the advantages of "No. 3 sirocco" which Mr. E. M. Hay of Goorokoya was certain would vanish no further acquaintance with a machine which in his experience did excellent work. The circumstance of Logie and Belgravia estates this season giving 11,000 bushels of coffee already gathered, with perhaps 1,500 to 2,000 more to come in, is encouraging to owners of the old product; for we believe not much manure was used to secure this result. The maximum crop of these estates has however been so high as 23,000 bushels; but the half of this with the present economy in working, will pay. Another instance of a change for the better is found in the case of an old Dolosbagie property which in 1882, after an apparently good blossom, yielded for its harvest, but *ninety* bushels of coffee! Now the same place this season, gives its 1,100 bushels of coffee, 20,000 lb. cinchona bark, and a good many thousands of lb. of tea. That is the experience we should like to see realized on a great many of the old properties. In connection with Mariawatte and its fine tea returns, the question was raised as to whether it (as Weyungawattie) had ever done much in coffee although freely manured. Mr. Borron who, twenty years ago thought it amongst the finest-looking sheets of coffee he had ever seen, never heard of good crops; but Mr. H. Blacklaw tells us that in 1860 it yielded some 13 cwt. an acre and, perhaps as a consequence, never did much afterwards although freely manured. The question then will be, is the tea now benefitting by the manure which the prematurely weakened coffee trees were unable to take up? Sir J. B. Lawes, of agricultural fame, expressly rules that the benefits of substantial manuring often extend over twenty years. Sinniapitiya, the property of the O. B. C. creditors, close by, promises to be another Mariawatta in success but with more diversified products. The question is asked why old Atgalla with its equally good lay of land and, possibly soil, on the other side, has not been taken in hand; but this only brings us face to face with the "thousand of acres" which the "old Colonist" V. A. says he can point to, as good as Mariawatta, in Kaduganawa, Allagalla and the region thereabout for tea. Our companions were certainly loud in praise of much of the soil between Gampola and Allagalla: finer paddy straw or better fruit trees are not found any where else upcountry. (By the way, has anyone else noticed the resemblance between the grassy hills on this side of Gampola to the lead and coal hills of Lanarkshire as pointed out to us by "Logie?").—But we are bound to say that if there are encouragements to keep good coffee intact, we heard and saw enough upcountry to show the foolishness of cultivating miserably poor worn-out coffee. Apart from the utter ruin wrought in coffee in Matale and Kaduganawa, by bug (has this pest anywhere touched tea?) a Pussellawa planter was clear that his proprietors had sacrificed large annual profits derived from Cinchona by spending it on coffee which gave no return. Many old plantations have, it seems, yielded bark enough of late years to pay well, had the outlay on non-paying coffee been stopped. But then 'May not the coffee in some of these cases, yet come round as on the typical Dolosbagie estate we have mentioned,' will be the question asked.

However, if we are to satisfy "Moderation," we must go higher up and deal directly with tea. Messrs. Forbes, Aspland, Grigg and Blacklaw have within the past few days, given us very favourable accounts of the growth and promise, aye and yield of young tea in Ambagammuwa, Lower Dikoya, Upper and Lower Maskeliya respectively. Of the good yield in these directions there can be no doubt and improvement in preparation after the pattern set by Gallabodde and Blackstone, will also go on. We are pleased to learn that Mr. Wm. Rollo and Mr. John Walker, now on a visit to Ceylon, have expressed themselves well satisfied with our tea prospects.

Higher up still, we had an opportunity—though only a brief one,—of marking the really wonderful flush on the vigorous and luxuriant tea-bushes covering the Abbotsford fields at 5,000 feet and upwards. The figures recently given by the manager must convince even "Moderation" that there is more in tea at a high elevation than he had supposed. In the neighbourhood of Nuwara Eliya we had the opportunity of going carefully through several tea fields, not of large extent but sufficient to enable a judgment to be formed on the question before us. Some 36 acres under the small-leafed, shrubby but hardy China plant on Hazlewood, eastward of the Plaine, on an exposed, rather bleak, and by no means fertile spot, are giving satisfactory returns up to and in excess of 300 lb. per acre although widely planted and hitherto, not regularly plucked. On this easy lay of land, and with a slow growth of weeds, the Assam system of digging in the grass and weeds three or four times a year is adopted, with a saving in working, and great benefit apparently to the tea trees.

No. II.

Assam-hybrid tea 6,000 feet above sea-level yielding 500 lb. and upwards.

Mr. Rossiter's tea factory is situated close to the main road on Fairyland about 3 miles from Nuwara Eliya, and in it he prepares the leaf plucked from the hybrid tea in the surrounding garden; from the field of China on Hazelwood three miles away; from some 14,000 bushes in bearing of fine Assam tea on Capt. Bayley's Pedro property close by; from Mr. Grinlinton's Portswood estate, two miles farther on; and from Kandapolla, six miles distant from the factory. These properties as yet have so small an area, or rather number of bushes ready for cropping, that it suits the proprietors very well to allow Mr. Rossiter do the plucking with his own coolies and to receive payment at the rate of 4 cents per lb. for the wet leaf. As yet it is the day of small things all round for tea crops in this neighbourhood; the total outturn from the Fairyland factory last year not exceeding 15,000 lb., although during 1885 Mr. Rossiter hopes to prepare and dispatch some 36,000 lb. Enough has, however, been done in plucking leaf from mature trees carefully counted, to give the information desired by our correspondent "Moderation" as to the probable yield of tea at a high elevation Of course, it may be said that cultivation carried on in comparatively small patches and the statistics of harvesting from trees irregularly planted with abundance of room, afford no fair criterion for a regularly planted garden. But the margin afforded by last year's experience is we think wide enough to allow for any such deductions. In our last we said the hardy China tea scattered over rather more than 30 acres on Hazelwood, had given in 1884 about 300 lb. made tea per acre. The return was fully equal to this if allowance be made for numerous blanks and for somewhat irregular plucking during part of the year. But there is the greatest contrast in the world between the hardy China alongside the Hakgala road, and the luxuriant Assam hybrid bushes from 5 to 8 years old seen on each side of the Udapussellawa road, on Fairyland, or scattered over one or two fields of Capt. Bayley's very fine Pedro property, and again in the rich hollows of Portswood (Mr. Grinlinton's). Both of these latter are primarily cinchona plantations which have yielded already heavy crops of bark, from most valuable groves of officinalis and robusta trees—some of really splendid growth—still covering large portions; but both proprietors are going in extensively for tea, having flourishing nurseries with a good lot of plants ready to cover a considerable area now to be cleared. Captain Bayley has had his tea bushes which have been plucked during 1884, carefully counted, the result being 14,000 which if taken as equal to 5 acres, shows a return of 505 lb. of made tea per acre. Mr. Rossiter's trees on Fairyland are fully older and they have certainly done wonders, since he says that off 6 288 full bearing trees, there have come no less than 11,505 lb. of wet leaf or 2,876 lb. of prepared tea. This would be at the rate of from 900 to 1,000 lb. per acre! We have not got the number of trees in bearing on Portswood; but the full return of each month's plucking as kept at the Tea Factory is as follows:—

1884.	Fairyland.	Pedro.	Portswood.	Hazelwood.
	lb.	lb.	lb.	lb.
January ...	162	534	—	2,353
February ...	652	940	547	2,298
March ...	953	1,560	599	2 015
April ...	443	784	1,018	3,728
May ...	1,221	986	215	2,918
June ...	1,015	1,502	910	2,037
July ...	552	373	544	1,765
August ...	—	706	—	—
September ...	1,702	936	—	4,275
October ...	815	412	307	3,288
November ..	1,481	590	1,267	4,762
December ...	2,509	787	146	3,591
Total wet leaf	11,505	10,110	5,553	33,030
Made tea (¼)	2,876	2,527	1,388	8,257

Capt. Bayley remarks of the Pedro tea:—

I gave you the yield for 10 months once before; the other two months have brought down the average, but it seems to me satisfactory for 6,500 feet above sea-level. The tea was allowed to grow up anyhow and was pruned down with cutties as I wanted to let light on to the cinchona I planted between. I am going to have it pruned down now somewhat more scientifically, and will see what it does after that.

Mr. Rossiter says of the same tea and of the prospects generally of the neighbourhood:—

I am satisfied that the clearing would have given fully double the quantity it did, had it been properly pruned early in the year. At all events it is satisfactory to know that land at this elevation is safe to yield over 500 lb. of tea per acre per annum and that without any extraordinary cultivation. For planting a new clearing here, I would advise 4 × 4, and if the vacancies are kept filled up as they occur, the clearing sheltered and the young plants protected from the cold winds, the owner is safe to get as follows:—

2 years from planting	150 lb.	per acre.
3 do	do 300 do	do
4 do	do 400 do	do
5 do	do 500 do	do

This latter figure can be kept up for years to come for our soil is second to none in the island, and our climate is perfection for the endurance and lasting of the tea plant. The tea abovementioned, runs up to 6,500 feet above sea-level, very nearly as high as any on the Oliphant e tate, where the result of cropping for some years has not given so good an average return, we believe. There was some talk of tea of an inferior jât being condemned to be pulled up on this property—a mistake, if committed, we should think—seeing that even the small-leafed hardy China tea is well adapted for high exposed situations, and on Hazelwood, Mr. Rossiter quite expects it to yield up to 400 lb. per acre this year. Farther Eastward in Udapussellawa, we learn that on Goatfell estate tea is doing exceedingly well up to 6,800 feet. We suppose this is about the highest clearing in the island?

Portswood and Tulliboddy (recently purchased), together make for Mr. Grinlinton a compact property in one block of about 500 acres, much of it covered with valuable and promising cinchona. The bark now being harvested is very fine and samples of 'renewed' lately analyzed in London from this estate have yielded splendid results. Tea is however to be freely put out on both places as well as on Messrs. Delmege's Court Lodge estate above, where the cinchona fields protected by blue gums also look very flourishing; the most satisfactory experiment of this kind however in the neighbourhood of Nuwara Eliya is found in the regularly planted fields of cinchona with belts of blue gums on Lover's Leap estate. Altogether as a Cinchona and Tea district, the neighbourhood of Nuwara Eliya and Kandapola, nearly all over 6,000 feet altitude, affords much reason for anticipating good and permanent results,

FOREST TREES AS THE BANE AND ANTIDOTE OF TEA BUSHES:

THE POISON TREE OF CEYLON—THE RENOVATING TREE OF ASSAM AND ITS WONDERFUL PROPERTIES—WORTH TRYING AMONGST OLD COFFEE AS WELL AS IN TEA LAND —TWICE AS MUCH TEA LEAF YIELDED UNDER THE SAU TREE.

We recently noticed pretty fully our identification of a tree growing in the forest in Dimbula, as the poison tree, the trunk and roots of which, in the process of decomposition, prove fatal to considerable numbers of tea bushes, as many as a dozen of the latter sometimes dying around one trunk of the tree in question. Having sent specimens of roots and foliage of the living tree to Dr. Trimen and Mr. W. Ferguson, they were able to specify the tree as *Symplocos obtusa*, Mr. W. Ferguson having previously decided from the characteristics of the timber that the tree was a *symplocos*. As most of the species of trees so named are possessed of powerful juices which act as tans or dyes, our inclination has been strongly to believe that the tea bushes were killed by the juice of the *symplocos* when their feeding rootlets came in contact with its roots or trunk. But we have reason to suppose that Dr. Trimen, who has kindly promised to report fully on the tree and its properties, leans to the belief that the mischief is due to *baccilli* or *fungi* developed in the process of decomposition of the *symplocos*. Pieces of root taken out of the ground in which they had been buried for half-a-dozen years or more were certainly marked by products of decomposition: fungal or insect, Dr. Trimen will probably say. We await with interest the doctor's report on a tree which tea-planters certainly ought not to leave, as they do other forest trees, to the natural process of decay in their plantations of tea. We have stated that our attention was first called to the tree and its deadly effects on tea bushes by an Assam planter. But, if from Assam we heard of the bane of tea, we now from the same quarter hear of another tree, *Albizzia stipulata*, which is an antidote to age in tea bushes, and exhaustion or sterility of soil, and also a preventive of blight. This tree, the Assamese name of which is *sau*, and which, it seems, was formerly ranked with the acacias, grows on the Himalayan slopes to the altitude of 4,000 feet above sea-level. It ought, therefore, to flourish to any height in Ceylon in which tea is cultivated. Wonderful and most encouraging details respecting this tree are contained in a pamphlet which has been issued by the Calcutta Tea Syndicate. There are albizzias in the forest flora of Ceylon, but we are not certain as we write if *A. stipulata* is included. If not, we have no doubt the seeds can easily be procured. So satisfied are many Assam planters of its virtues that they are diligently planting it out amongst their tea at the rate of 100 trees to the acre. It is of rapid growth, so that it will speedily yield that partial shade to which some of its beneficial effects are attributed. There may be some property in the leaves inimical to blight, which never attacks tea under its shade, although it may be virulent immediately beyond the scope of that shade! That is much, and in this tree we think we see the answer to the objection of Coylon planters growing vast expanses of tea, and consequently suffering again, as we already have done, from alleged outrages on nature's balance by devoting attention exclusively to the growth of one product. But the leaves, even when the moderate foliage of the *sau* tree reaches the surface of the soil, cannot, it would seem, possibly be the cause of the marvellous renovation of exhausted bushes and sterilized soil, which the growth of the *sau* or *Albizzia stipulata* over a tea field is said to produce. One theory is that the great roots of the tree penetrate and drain the subsoil, while its lateral roots open up and ameliorate the surface soil. But some positive fertilizing action or property, above and beyond draining and opening the soil, seems to be possessed by the tree, for Mr. E. S. Peal, one of the oldest, most observant and scientific of the Assam tea planters, records that even in the process of decomposition the benefits conferred by this plant on soil and cultured plants is much greater than in the case of other forest trees. It would thus appear that the *sau* is the very opposite of our *symplocos*: a nourisher instead of a destroyer of useful vegetation, and it may be an experiment worth trying what the effects of *Albizzia stipulata* may be on old coffee land and on coffee bushes, diseased from attacks of leaf fungus, bug, grub and other "enemies of the coffee tree." Besides our native albizzias one has been introduced from Java. In consequence of a glowing account of the merits as a shade tree of *A. Molluccana*, in a report on the Buitenzorg Gardens by a former Director, we obtained seed, and the tree grows luxuriantly on Abbotsford up to over 5,000 ft., the foliage closely resembling that of the magnificent "Madagascar tree," *Poinciana regia*. But the extreme brittleness of the tree renders it a nuisance, and, as we saw in Java, renders it mischievous and even dangerous as a shade tree. There is no such objection stated in the case of the Himalayan albizzia. It is only said of it that its timber is not very durable, and yet it is added that it is used for furniture, &c.

We may say that Mr. Peal while testifying to the merits of the *sau* tree and "even better" the *medeola*, which he identifies with *Albizzia elata*, mentions, also the names of trees, *hingori*, *sawa* and *sum*, which are inimical to tea. On turning to Gamble's valuable Manual of Indian Timbers, we find that the above are vernacular synonyms for Himalayan oaks, ashes and birches! This is curious, because in Johnston's Agricultural Chemistry the oak is placed first in the list of trees which add value to soils by the shedding of their leaves. But then the oak, like the Turk, "bears no brother near the throne." We do not understand that the Himalayan representatives of our leading European forest trees possess any specially injurious quality. It is only probable that they use up the fertilizing constituents of the soil and leave nothing or but little for the tea. But, as we suspect *Symplocos obtusa* of an absolutely poisonous property, so Mr. Peal asks regarding the beneficial trees: "What is the chemical that the *sau* and *medeola* roots evolve? Worth knowing." We should think so, for he states:—"The benefit to tea is obviously neither shade nor drip, but some chemical process due to the *roots*, as the effects on tea is often seen long after the tree has been felled, and the stump alone remains, at times DEAD." Just so, it is the dead stump and roots of *Symplocos obtusa* which kill our tea bushes, and we should like to know what the chemical property is which either directly or through the agency of organisms which it develope proves fatal to young and healthy tea bushes which have the misfortune to be planted in contiguity to this fatal tree.

Our readers will not understand us as advocating shade trees for tea in Ceylon; but if soil can be improved and blight warded off, by interpersing *Albizzia stipulata* through the plantations, a very great gain may be secured, and experiments are worth trying. Having thus given the gist of the statements contained in the pamphlet issued by the Calcutta Tea Syndicate, we now proceed to make extracts from that

portion of it reprinted in the *Indian Tea Gazette*, so that our readers can judge for themselves as to the correctness of our representation of the statements made and the value of those statements regarding the recuperative effects of *Albizzia stipulata*. The gentleman who set the ball rolling was Mr. J. Buckingham of Amgoorie, who in October 1884 wrote as follows:—

The "Sau" (Albizzia Stipulata) is fully described in Gamble's Manual on Indian Timbers, page 160. It is common in most parts of Assam, and may be generally found on land lying rather low. Some years ago a gentleman in Upper Assam first drew the attention of tea planters to this tree (see Tea Cyclopædia, 198), very properly calling it a tea fertilizing tree; but it is only within the last few years that experiments have been made to prove that the "Sau" tree possesses peculiar properties in bringing round exhausted soils thereby causing tea bushes to flush vigorously, in fact, imparting a vitality which we are now beginning to find old tea sadly deficient in.

I am not in a position to state the reason of the "Sau" exercising such an influence on tea, and I believe a thorough chemical analysis of the soil can be the only means of ascertaining the cause.

An area of three acres planted with "Sau" about 10 years ago has yielded for the last four years more than double as much tea as any other part of the garden.

I think we may put aside shade as the cause of this increase in yield; in fact, the generality of planters condemn shade. It tends to make the bush throw out long stalky shoots, racing with each other to reach the light, and the flushes from such trees are necessarily meagre and woody.

Such, however, is not the case under "Sau." The tea bushes under this tree, which casts a light shade, are broad in proportion to their height, have an even growth over the whole surface, and yield flushes equal to the finest tea I have seen in the open, where the condition of the soil and age of bush are both in its favour. I do not wish to contend that "Sau" is capable of improving tea plants, where the soil contains elements which in some instances nature has abundantly supplied for the support of the bush, but I do assert that the vitality of the tea bush is limited, probably in a great measure depending on the character of the soil, and unless we restore some of those essential parts, we are yearly, I may say weekly, abstracting, the tea planter in a few more years will find himself surrounded by tea which the very best cultivation and the most scientific pruning can never bring round.

The mere fact that blight has during the last few years been more prevalent than formerly, strengthens the argument that soil is deteriorating, and there is the strongest proof to show that tea under the "Sau" is particularly free from blight when the surrounding trees are suffering.

Professor Johnson, in his Elements of Agricultural Chemistry, says, the improvement of land therefore by the planting of trees depends in part upon the quantity of organic food which the trees can extract from the air, and afterwards drop in the form of leaves upon the soil, and in part upon the kind and quantity of inorganic matter which the roots can bring up from beneath, and in like manner strew upon the surface. The action therefore of a tree is two-fold;

1st.—It causes vegetable matter to accumulate on the surface.

2nd.—It brings up from beneath certain substances which are of vital importance to the growth of plants, but in which the upper soil may have been deficient. The same author also proves that land can be improved ten-fold by planting trees.

In some trees certain mineral salts are supposed to exude from the root-cells into the water of the soil, these salts acting in some instances, we all know, as a poison. From the same cause may not some mineral salts prove beneficial to the tea bush?

My object in collecting the following circumstantial proofs of the efficacy of the "Sau" principally, and of a few other trees, partially in restoring exhausted soils, is to call the attention of the tea planting community generally to this important fact, and to urge the necessity of a careful chemical investigation of the matter on the spot. My thanks are especially due to the gentlemen who have come forward so liberally with their opinions in this matter.

There are the important facts stated by Mr. Buckingham, that a plot of tea land planted with *sau* trees ten years ago has for four years back yielded twice as much tea as all the rest of the garden, while the bushes which gave the double yield of leaf were particularly free from blight. With reference to the quotation from Johnston, we may say it is beyond doubt one of the functions of forest trees to pump up water from the lower subsoil strata, and with the water, it may be taken as granted, some of the fertilizing ingredients in the subsoil are also brought to the surface. Why some trees should be specially beneficial in this and other respects does not seem to be known. But such is the fact, opposed to the other fact that certain trees are not only not beneficial but inimical to cultured plants. Next comes

Mr. Newington, who writes regarding the "Sau" tree:—

I was out at one of the out-gardens this morning and took particular notice of tea growing under the "Sau" trees. I feel confident that it is beneficial to the tea plant, and will increase the yield. In the first place, it is a cultivator, as the lateral roots grow so near the surface, which seems to open the soil and make it porous; then again I notice this tree does not thoroughly open its leaves until about 8 a. m., just when the sun is getting hot. When the leaves are quite open it gives a slight shade, while at the same time it does not exclude the sun; this is beneficial to the tea plant. Also this slight shade prevents the ground getting dried and baked by the heat of the sun. As far as the fact of the leaves acting as manure is concerned, this is very slight, as the foliage is comparatively light. I quite believe in the tree. For the last three days I have been planting out my "Sau" nurseries among the tea 50 × 50.

Now as regards the lateral roots of the tree being surface feeders, that might be rather an objection if the roots fed on the same substances as tea requires and did not, on the contrary, add to the soil, fertilizing matter drawn up by the larger roots from the subsoil. The mere mechanical opening up of the soil is, of course, beneficial, but this alone would not account for the good done by the *sau* tree. Next

Mr. Raban writes:—Regarding the "Koroi" or "Sau" tree, from what I saw at Amgoorie, I was quite convinced that it benefited the tea growing under it, so much so that I have this year planted out 100 acres of it myself. I find it difficult to account for the beneficial effects it produces on the tea plant but it is possible that Acacia trees take up nourishment from the soil not required by the tea plant, give sufficient, not too much shade, keep down jungle, and, sending their roots down much lower than the tea plant, drain the subsoil and enable the latter to send roots down lower than it otherwise could. I do not say this is a sufficient or satisfactory explanation, but it is the only way I can account for the beneficial effects produced.

Then, Dr Simons writes:—

I will endeavour to give you all the information I can collect about the "Sau" (Acacia Stipulata). It is a tree worth cultivating among tea more than any other I am acquainted with, for in the way the branches spread, it does not keep the sun entirely off the plants, but moderates the strong heat of the sun's rays, through which evaporation from the leaves is lessened and the flushes come in quicker and larger than on those growing exposed in the open. The "Sau" grows to a very large size and quickly. Dr. Roxburgh in his "Flora Indica" states that one tree planted by himself had a trunk 48½ inches in circumference, 4 feet above the ground, when only 7 years old. Another tree in the Botanical Gardens 20 years old measured 13 feet in circumference. I do not know whether you took notice of the "Sau" tree which was growing in Borsillah Factory, not 100 yards south of the Iron Tea house; I once measured the trunk and as far as I can recollect, 3 feet above the base it was 14 feet in circumference, and the branches spread over at least one twentieth of an acre. There were no vacancies among th

tea plants growing underneath it even to within a few feet of the trunk. They always looked uniformly healthy with deep green leaves, while those growing in the open not far off had several vacancies; some looked healthy, but the greater portion looked scraggy with leaves of a pale greenish yellow colour, and would be often affected by blight, either red spider, green fly and fungoid spots on the leaves.

The "Medeloa" (Acacia Elata) which I presume you know as "Koroi" is another desirable tree to grow among tea, but from its slow growth and not having spreading branches, it does not answer so well as the "Sau."

The timber of the "Sau" is not useful for posts as it decays in the ground quickly, for marolies and planks it would answer, but it is rather brittle. Natives scoop out old trees for canoes, which they say last longer than those made of the Poona. It makes excellent charcoal as it burns slowly.

I would surmise, by your writing to gain information about the "Sau," that you want to plant it among tea as a shade. I think it is time that a move is made in this direction, for in consequence of the indiscriminate cutting out of all trees, and leaving none for moderate shade to the tea plants, all the blights now prevailing have been introduced. Fruit trees require planting in the open to receive the heat of the sun, but to treat a plant from which the leaf is required, moderate shading is necessary to prevent evaperation from the leaves.

Again Dr. Simons writes:—

Mr. Macdonald told me there are some "Sau" trees growing among tea in a garden named Burasoli of the Grob Company, and cover about 5 acres of plants. He is of opinion that the tea plants growing underneath the shade of these trees have looked uniformly healthy and kept free from blights, while those in the adjoining open land are generally affected by blight when prevalent. The yield of the whole garden has averaged 8 maunds per acre, but he considers the greater portion of this yield is plucked off from the plants growing under the "Sau" trees.

It will thus be seen that Dr. Simons attributes blights to the indiscriminate cutting down of forest trees. Next comes

Mr. Peel, who writes:—

Yours of 7th to hand, and I have noticed for many years what you allude to regarding "Sau." I first clearly noticed its value in tea at Bursali in 1868, and later on found that "Medelea" was even better: I fancy it is peculiar to all that group, *i.e.*,

Medeloa	Albizzia	elata
Sau	„	Stipulata
Hiris or Siris	„	Procera or Sirisa
(Jati) Koroi	„	Marginata or Odoratissima

These used all to be called "Acacias."

The benefit to tea is obviously neither shade nor drip, but some chemical process due to the *roots*, as the effect on tea is often seen long after the tree has been felled, and the stump alone remains, at times "dead." I have planted "Medeloa" by fids of root best, and it grows easily. Yes, Hingori is bad, and Sawa which Dr. Simons calls "Euglehardtia Roxburghiana," is "worse," and I have seen "Sum" bad. What is the chemical that the "Sau" and "Medeloa" roots evolve? Worth knowing.

Messrs. Philips and Lawrie write in the same strain. Mr. Walker objects to shade of any kind. Mr. Macdonald holds a contrary opinion and writes:—

This garden has been repeatedly attacked by red spider and green fly. I have never noticed the former touching tea near a "Medeloa" although all around might be perfectly black; the green fly does attack it, but does not seem to do any thing like the damage it does outside the radius of the tree.

Another garden of the Company's 12 miles off has a plot of indigenous "Sau" tree, probably not more than 10 trees to the acre. I have seen all sorts of blights in this garden, which is only a small one, but have never noticed any on this plot for the last nine years. I cannot say what the probable yield of this plot may be, as it was never kept account of, but judging from the steady outturn of from 7 to 8 maunds an acre for the whole garden, including some very poor plots indeed, I should think it cannot be less than 10 maunds an acre. Many trees are good for tea such as "Amluckie," "Modar," &c., but not to the extent that these are. I am not in a position to say how tea is actually benefited by shade or chemicals in the soil genial to it. It is a subject that certainly should be brought to the notice of proprietors in a manner that it would leave little doubt in their minds as to the experiment being at least worth a trial.

Mr. Eyre writes of the extraordinary effect of the *sau* tree in benefiting tea and suggests a chemical analysis of the leaves. Mr. D. Lumsden recognizes the benefit conferred on tea by the *sau* tree. Mr. Gibbons is entirely opposed to shade of any kind.

Mr. Pringle writes:—The seed I got from you never came up, so I should very much like to get some more and give it a trial, as certainly from what I saw at Amgoorie I think there is no doubt it is beneficial to tea.

I have a good many "Koroi" trees scattered about the garden here, and since you drew my attention to the matter, I have noticed that the tea looks uncommonly healthy and well grown in their vicinity. It might be that the "Koroi" keeps a happy medium in taking moisture out of the soil enough in the rainy weather, and not having any heavy foliage to keep the sun from getting at the soil round about it, and not taking too much in the dry season. Here I notice that most trees dry up the soil tremendously round about them in the cold weather, and the drip from heavy foliage in the rains is certainly bad. Jak trees I have found deadly for tea.

No doubt the foliage of the jak tree is too dense for tea.

Mr. Dowling of Chittagong writes:—(Alluding to the "Albizzia Odoratissima" or "Jati Koroi") Bengal "Siris."

The tea bushes are decidedly better under this tree than in the surrounding parts, and the "Koroi" also improves the tea in light soils but not in clay.

Then follows Mr. Earnshaw, who writes:—

It would be most interesting and useful if the chemistry of the question could be explained to us, as without understanding that, it is difficult to venture an opinion as to the reason of the good done by these trees. It would seem that somehow their roots, in drawing their nourishment from the soil threw out the property which the tea tree required in this way restored to the soil what had been taken out of it, to an excessive extent, by the tea.

I hear it has been noticed that young tea is not much affected by these trees, and the benefit done is in *old* gardens; this would point to the feasibility of the above idea. The leaves of these trees are so small and light that they would hardly act as manure to any appreciable extent, but that the light shade is useful in checking excessive and sudden heat from the sun seems quite reasonable, I think. The fact that the beneficial effects are to be seen in tea around stumps of "Sau" confirms the correctness of the root action theory, but would not altogether exclude the probability of some good arising from the light shade when it was present.

Whether the gases thrown off from the leaves of these trees could in any way affect the tea, only a chemist could say. It certainly would be worthwhile to have the whole question gone into by a scientific man, as it seems very certain that in many old gardens something is wanted to restore vigour to the tea trees and to stop the mortality which is going on among them to a considerable extent from some cause or other; and if by planting certain trees which are close at hand, old gardens can be very materially improved, the fact should be realized and acted on as soon as possible.

Our readers have thus this case before them and can decide for themselves the question of introducing and cultivating *Albizzia stipulata* on tea estates. We deem it well worthy of a trial. The effects of the albizzias indigenous to our forests might also be observed and reported on.

We may add, as a contribution to any enquiry into the benefits conferred or the mischief effected by certain forest trees, that when we visited the Ouchterlony Valley, the late Mr. Grant drew our attention to coffee trees dead or dying from being planted around trunks of the "wild cinnamon tree,"

ALBIZZIA STIPULATA, THE RENOVATING TREE FOR TEA PLANTERS.

Having now referred to Thwaites' *Enumeratio*, we find that the tree so favourable to tea cultivation is quite common in Ceylon up to 2,000 feet. As it grows in the Himalayan regions, 20° north of Ceylon, to 4,000 feet, we need merely repeat our conviction that it will flourish here to any elevation to which cultivation has extended or is likely to extend. From the extract we quote it will be seen that there are four Albizzias indigenous to Ceylon, the Sinhalese name of *A. stipulata* being "Kabal-māra-gaha; *A. odoratissima* being known to the Sinhalese as "Huri-māra-gaha." One of the writers in the pamphlet mentions "Amlukie" and "Modar" as good for tea. We find that Amlukie is one of the native names applied to *A. stipulata*. It is also the Assamese name of *Phylanthus emblica*, of which Gamble states that "the bark is used for tanning and in medicine; chips of the wood are said to clear muddy water." The fruit is the emblic myrobolam and is used as a medicine, for dyeing, tanning and for food and preserves. It gives a gum which is not used. *P. emblica* is the common "nelli-gaha" of our patanas, which is found up to 4,000 feet. We should never have supposed that this tree could be useful to tea. Thwaites says "the fruit of this tree is much esteemed as a medicine by the Singhalese. The timber is used for buildings." "Modar" is not in Gamble's list of vernacular names, but we find "Modhuriam" as the Assamese name of *Psidium guava*, introduceed from America and now semi-wild all over India. It is cultivated for its fruit, the bark is used in medicine as an astringent and the leaves for dyeing in Assam. The following is the list of Ceylon Albizzias :—

70. Albizzia, Durazzini, Benth.

1. A. Lebbek, Benth. Hook. Journ. of Bot. iii. 87 Walp. Rep. v. 596.—*Acacia speciosa*, Willd.; W. et A. Prod, i. 275, cum syn.—C.P. 3,130.

Hab. Anooradhapoora, *Mr. Brodie*; banks of the Ooma Oya, in the Badulla district.

2. A. odoratissima, Benth. l. c. p. 88; Walp. l. c.—*Acacia odoratissima*, Willd.; W. et. A., l. c. cum syn.—C.P. 1,529.

Hab. Warmer parts of the island, up to an elevation of 2,000 feet. Nom. vulg. "Hooree-mara-gass."

3. A. amara, Boivin, (Benth. l. c. p. 90; Walp. l. c. p. 597.)—*Acacia amara* Wild.; W. et A., l. c. p. 274, cum syn.—C.P. 1,518.

Hab. North of the island, *Gardner*.

4. A. stipulata, Benth. l. c. p. 92; Walp. l. c. p. 598, cum syn.—*Acacia stipulata*, DC.; W. et A., l. c.—C.P. 1,517.

Hab. Warmer parts of the island, up to an elevation of 2,000 feet. Nom. vulg. "Cabul-mara-gass."

Mr. W. Ferguson writes to us as follows :—

"The *Albizzia stipulata*, Boir., is quite a common tree in the Western Province of Ceylon, and is well-known under its Sinhalese names Kabal-mara or Hulan-mara. It is a high tree, and, as its specific name indicates, is remarkable for its large stipules. When in flower it is a very beautiful plant. The closing up of the leaves of this tree at night is common to the Leguminoseæ, but I think this group of plants is more sensitive to the want of light and the leaves droop as soon as the sun sets. The tree seeds freely, and seed can easily be procured. The tree that is so fatal to tea plants after it is dead is no doubt the large Ceylon form of *Symplocos obtusa*, Wall., and C. P. 1820. The specimens of roots of this tree sent from Abbotsford are very much affected with dry rot, and it is likely that this fungus affects all the living plants near it."

THE TEA TRADE IN 1884: THE RELATIVE POSITIONS OF INDIAN AND CHINA TEA.

SUPPLY AND DEMAND—TEA PRICES—INDIA, CHINA AND CEYLON—PLUCKING AND SORTING—GOOD PROSPECTS.

Coffee has been at a low ebb during the past year, but we cannot, in view of the prices of 1846-49, say of this article, as we must say of wheat, of sugar and of tea, that never in the world's history were they to be obtained for so little money. If, as we suppose, competition amongst retailers has in the end given the consumers a large portion of the benefit thus secured, we may well affirm that, whatever be the case with the owners of capital and the conductors of agricultural enterprize, never before were the wages-earning class in a better position as regards the necessaries and even some of the luxuries of life. Supply in almost every commodity and even in shipping has overtaken demand, and prices and profits have gone down in proportion. As regards tea, the British planters on the banks of the Brahmaputra and on the slopes of the Eastern Himalayas, equally with the toiling peasantry on the borders of the Yang-tze-kiang and in the neighbourhood of the Yellow River, have felt the effects of their own enterprize and industry, in the shape of lowered, in many cases utterly inadequate, returns. The consumption of tea, in Britain at least, has increased, and is increasing, until it has reached 5 lb. per caput of the population; but as the supplies poured in from India and Java, added to China and Japan, are beyond the demand for consumption or for export, the process of selection has gone on rapidly to the detriment of China and the comparative benefit of India. "Comparative" we have written, because, although India is rapidly gaining on China in the matter of consumption, prices for the better tea as well as for the inferior have gone down to an unprecedented level, to a level indeed which but for and even with all advantages of labour-saving machinery must leave a loss to many Indian "concerns" as well as to the cultivators and the middlemen of far Cathay. The contest is at present between China and India, and the representative of modern civilization is rapidly driving its ancient rival from the field. Ceylon has commenced to intervene and will soon be seriously competing with both, and her ultimate success will depend as largely on keeping up the high quality of her produce as on the increasing quantity she will send into the markets. Of course neither skill nor care can always counteract the effect of meteorological conditions, but we need not advise our planters to do their best, because we know they quite appreciate the situation and their own prospects and responsibilities.

The history of the tea trade in 1884 as regards both China and India is summed up in an elaborate review by Messrs. Stenning, Inskipp & Co., which we should gladly publish in full, did space permit. That being impossible, we proceed to summarize the main facts and figures. To many the results of the China trade must have been disastrous, while, shortly stated, the history of the Indian trade for the past year has been equally disappointing to grower and importer. The season, generally, in India was not favourable to quantity and quality of leaf, and prices, as we have indicated, reached their lowest level. But we cannot doubt that the beneficial effect of largely increased consumption in the future, arising from low prices now, will tell in favour of those who produce the best article. And in this respect Ceylon is not likely to fall behind. In the summary generally

gloomy as regards Indian tea, our Ceylon product is thus noticed :—

Ceylon.—There has been a marked increase in the supply, and as last year's good quality has been fairly maintained, the teas have met an active enquiry, buyers finding them most useful for mixing purposes. The average price of 15,701 chests sold since 1st August, 1884, is 1s 2¾d per lb.

Considering the very low prices generally, the average of 1s 2¾d per lb. is encouraging, but we are rather staggered at the remark that our teas are found most useful for mixing. We had hoped, and we still believe, that the Ceylon teas will make their way on their own intrinsic merits, as combining exquisite flavour with fair strength. Java is advancing in the race of competition, and recently she has again tried the Australian market, which by right of contiguity ought to be hers. This is what Messrs. Stenning, Ioskipp & Co. say of

Java.—Efforts have been made, with some degree of success, to imitate in appearance the finer Indian makes but the disparity in value of liquors is still evident. Prices have receded to a low point owing to the fall in Indian and China Teas.

We quote what is said of plucking, sorting, &c. :—

Plucking.—The tendency in many gardens this season seems to have been to pick too freely, resulting in an undue proportion of Common to Medium Teas, and a low level of price. We may also point out that many estates have produced Pekoes much too twisted and wiry in leaf, and with a large quantity of stalk, such tea throwing a weak pale coloured liquor.

Sorting.—An improvement is noticeable, the number of breaks in Invoices being less than heretofore ; as a rule four, or at the most five, are all that are really needed, viz. :—Orange pekoe, or broken orange pekoe, pekoe broken pekoe, broken pekoe souchong, and pekoe souchong, with an occasional lot of tannings and dust, such an assortment should be practicable if the leaf be plucked moderately fine. Where a garden is producing but a small quantity, there should be as few different kinds as possible, with a view of avoiding small or non-sampling breaks.

Bulking in India.—Little advance seems to have been made ; many invoices being marked as "bulked" which on inspection, prove to be so irregular in quality that bulking here, to make the tea merchantable, is imperative ; buyers require that any one package of a break should be identical with the remainder, and if this were fully realized on gardens, bulking here might be done away with altogether, except when putting small lots together to make a fair sized break. It cannot be too strongly urged upon Factory Managers that to reap the full benefit of bulking in India, and nett weighing here the necessary conditions must be rigidly adhered to viz. : *thorough bulking at the garden and an equal quantity packed in each chest of the break* otherwise the labour and cost of bulking at the Factory will have been to no purpose.

Weighing Nett.—This system has made fair progress, but there is still a want of exactness, the variation often much exceeding the limit of 1 lb. either way, *i. e.* above or below. We reprint the rules from our review, for 1883.

Weighing Indian Tea.—The following are the amended regulations which came into force with the New Year, 1884.

The weight of Indian tea for duty may, if desired by the importers, be ascertained under the following regulations:—

1. The packages on arrival to be weighed to ascertain the gross weight of each package.

2. With each entry the importer to give an endorsement or statement of the nett contents of each package.

3. To test the accuracy of the endorsement or statement of the nett contents 10 per cent of each break to be turned out and weighed nett, but in no case should less than 3 chests be turned out.

4. If the variation in weight of the test packages be found to exceed 1 lb. the whole parcel to be weighed out. When the averages of the packages weighed nett amount to so many pounds and a half or more, the half or more will be charged as a full pound ; when the fraction is less than half-a-pound it is to be rejected and disregarded.

It will be evident that the only system that is satisfactory to the trade is that of "*average nett*," most buyers objecting to teas that have been turned out to obtain separate weights.

Marks on Chests.—Nothing is wanted, or is of any service here beyond (1st) garden mark, (2nd) description of tea, (3rd) garden numbers, and (4th) bulked (if such be the case). Gross, tare or nett, are not of the least use, and should be discontinued.

Small Breaks.—Under eight chests or eight half chests, or twenty boxes, are called "small breaks," and in order to save the time of the majority of buyers such breaks, although catalogued, are passed over until the conclusion of the day's auctions.

Size of Breaks.—Progress can be reported on this head ; but as quantities increase the number of chests should be larger, buyers here paying greater attention to large breaks.

Weight of Packages.—When a gross weight of 129 lb. is exceeded there is an additional charge of 8d per chest up to 159 lb. ; the following scale of charges fully explains this and deserves attention.

Management rate, per package, subject to 50 per cent discount :—

Gross.—160 to 199 lb. 4s 4d ; 130 to 159 lb. 3s 3d ; 80 to 129 lb. 2s 7d ; 60 to 79 lb. 2s 1d ; 45 to 59 lb. 1s 9½d ; 35 to 44 lb. 1s 4d ; 17 to 34 lb. 0 10½d ; under 16 lb. 0 6d.

We can understand the deprecation of too free plucking, but we scarcely know what is meant by pekoes being too much twisted : although the qualifications "wiry" and "a large quantity of stalk" probably explain the objection. But why should the marking of gross, tare and nett weights on packages be of no use? Surely, after a time, the figures of men proved to be strictly honest and trustworthy ought to be accepted, as well as their descriptions of qualities. But to come to the home consumption of tea in Britain. Figures differ in different statements, but, taking those before us as correct, the results are, that, in the eleven years between 1874 and 1884, inclusive, consumption of all kinds of tea went up from 139,378,000 lb. to 169,956,000 lb., an increase of 30,578,000 lb. The average for the last three years of the series is almost exactly 170,000,000 lb., against 147,300,000 lb. for the first three years. The increase so shown is 22,700,000 lb. The annual increase spread over the eleven years is about 2,761,000 lb. But the spring was great from 155,114,000 lb. in 1880 to no less than 174,050,000 in 1883, a rise of nearly 19 millions of pounds in four years. But the increase has been entirely in Indian tea. Ten years ago, in 1875, the proportion of China tea taken for consumption was 126,508,000 lb. while last year the quantity was only 106,918,000 lb., a decrease not far short of 20 millions, the exact figures being 19,580,000. The increase in the consumption of Indian tea in the eleven years has been two-and-a-quarter times the amount of the decrease in China. The figures are :—

Consumption of Indian tea in 1874	...	17,756,000 lb.
Do do 1884	...	63,038,000 ,,
Increase	...	45,282,000 ,,

In 1874 the proportion of Indian tea to the whole quantity consumed was only 12¾ per cent. In 1884 the percentage had risen to 37, or considerably more than one-third, while the period is evidently not far distant when India, aided by Ceylon, will not only equal but surpass China in quantity, there being no comparison as to quality, except in the case of very choice China pekoes. While China has gone down as we have shown, Indian tea has steadily increased over the whole eleven years, with the single exception of one year. In 1878 the figures had risen to 36,776,000 million, and in 1879 they were only 35,243,000. In 1880, however, there was a spring to 43,807,000. The advance has since been rapid until in 1884, five years subsequently, the figures reached 63,038,000, an increase of over 9¾ millions in five years. But, what is still more striking, there was an increas of four millions in the one year, 1884, as compared with 1883, the increase being about equal to the expected surplus of this season's export

from India over last. In the past four years, the deliveries of China tea have decreased 5,238,000 lb., while Indian in the same period has increased 14,202,000. The increase in Java has been from 1,315,000 lb. to 3,709,000, a rise of 2,394,000. In stocks the figures for China show a decrease from 86½ millions of pounds four years ago to 82½ now. In Indian there has been a rise from 18½ million to 26½. In Java the rise in stocks has been from 411,000 lb. to 876,000 lb.

There is a table which shows monthly imports, deliveries and stocks for the six years from 1879 to 1884. From the figures we gather that the deliveries of Indian tea in 1879 were under three millions of pounds per mensem.

In 1880	...	3,650,000	lb.
1881	...	4,072,000	„
1882	...	4,208,000	„
1883	...	4,925,000	„
1884	...	5,253,000	„

So that the increase of deliveries in 1884 over 1883 was equal to 328,000 lb. per month. The prospect is, that, if supplies keep up, the monthly consumption of Indian tea in 1885 may closely approach the average of six millions of pounds per mensem. That figure was exceeded in May 1884, when 6,062,000 pounds of Indian tea were delivered for home consumption. Counting the seasons from 1st June to 31st May, the deliveries of Indian and Ceylon were :—

For 1881-82	...	46,761,000	lb.
1882-83	...	56,621,000	„
1883-84	...	60,469,000	„

The figures for Ceylon tea alone from 1st June to 31st December 1884, were :—

Import	...	1,421,000	lb.
Delivery	...	1,179,000	„
Stock	...	545,000	„

In a few years hence, those figures will be left very far behind.

The summing-up of the whole matter as regards local enterprize is, that, even at present low prices, tea can be profitably grown in Ceylon, and that, in view of the rapid increase in the consumption of all teas, but especially of Indian and Ceylon sorts in Britain, the prospects of the "new product" here are exceedingly good.

PLANTING PIONEERS IN BURMAH :

TAVOY—AND MR. J. D. WATSON.

The voyage from Rangoon to Tavoy River has been so often described that I will skip over that part, and merely state that after a pleasant run of 29 hours, we found ourselves at the usual anchorage of the *Avagyee* at a place named Sinbugyin, some 25 miles below the town of Tavoy. This distance was traversed in the Launch *Opal* belonging to the B. I. S. N. Coy. and used for the conveyance of passengers and mails as there is an insufficiency of water for the *Avagyee*, but I have been informed that during coming N. E. Monsoon it is the intention of the Company to do away with the *Opal*, and carry a small launch on board the *Avagyee* for the conveyance of mails only, so that after this new arrangement comes into vogue, passengers will have to find their way to and from the B. I. S. N. Coy's steamers as best they may, a proceeding I think very likely to lead the majority of intending voyageurs for Tavoy, to avail themselves of the services of the Burma Steam Tug Coy, whose vessels steam within about a mile from Tavoy, and and are moored alongside a floating stage, which is certainly a more convenient mode of transit than having to make the trip down to the B. I. S. N. Coy's steamer in a native boat. Moreover, if I mistake not, the passage money *via* Maulmain to Rangoon is the same as going direct, and the amount paid for coolie hire on one's traps in shifting them in Maulmain would be counterbalanced by the saving of boat hire from Tavoy to Sinbugyin and *vice versa*.

Tavoy is a pleasant place, and I was not a little surprised at the comfortable houses built and inhabited by the natives, which are far superior to those of other towns I have visited in Burma, notably Rangoon, Maulmain, Bassein, and Akyab.

The streets are fairly wide and well laid out, and altogether there was a sleepy, prosperous look about the place that I was certainly not prepared for. There is a fair bazaar where most comestibles can be obtained, with the exception of mutton which is somewhat rare. Of course the ubiquitous Chinaman was to be found, and judging from the well-to-do, sleek expression on their faces, and the substantially built houses they occupied as a rule, I came to the conclusion that "John" was accumulating a pile. One peculiarity I noticed in the construction of the houses occupied by the Burmese, *viz* that instead of bamboo matting for walling, dunnee leaves are extensively used, and I fancy it is much cooler, at all events a house can be run up far quicker which is one recommendation. While in Tavoy I made the acquaintance of a Mr. James Watson a ci-devant coffee planter in Coylon, who has determined to see if coffee and tea, cinchona &c, cannot be raised equally well in these parts. He very courteously invited me out to his estate, which, by the way, he has called the "Model Duke Estate" consisting, if I mistake not, of some 150 to 160 acres, and situated about 3 miles and a half out of Tavoy. I spent a very pleasant day and was most hospitably entertained by him. After breakfast he took me over the estate, and although of course I have no experience of coffee or tea planting, yet I was much struck by the neat and systematic way in which the garden was laid out. Mr. Watson seems very sanguine of success and I sincerely hope he will in due time reap the reward of his labour and if he does there is no doubt others who will follow in his footsteps and thus open out a new source of industry and wealth for Burma. I had intended procuring some valuable information from Mr. Watson, previous to leaving Tavoy, but unfortunately I had no opportunity. I hope, however, to see him again ere long, and as on the occasion of my visit in question he very kindly promised to give me all the information he could on these subjects you may, I think, safely look forward to receiving an exhaustive account before long.—*Rangoon Gazette.*

COFFEE AND "BLACK BUG."—In speaking the other day of the destruction wrought by bug, we referred chiefly to old estates in Matale, Hunasgiriya, Hantane and Kadugannawa. In Pussellawa we learn that the enemy was successfully fought with mana grass, lime and manure. In most other places, fortunately, tea was ready to be planted where the coffee had given way and the growth is most promising. The Hunasgiriya Tea Company will soon have 2,000 acres under tea.

"FRY'S CEYLON CHOCOLATE," made up in neat packets bearing the proper island mark of a splendid tusker elephant amidst palm trees, is amongst thee latest importations of Messrs. Maitland & Co., Limited, Colombo. We read :—"This chocolate possesses a peculiarly fine and delicate flavour, somewhat different from that of chocolate prepared from cocoa grown in the Western Hemisphere ; and it will, we believe, be appreciated by many connoisseurs. The successful cultivation of cocoa in our Eastern dependencies marks a fresh departure in the trade in this increasingly important article of food and drink." We can testify to the goodness of the chocolate made from the choice cocoa imported from the island of Ceylon.

FOREST LEGISLATION IN CEYLON.

The Select Committee of the Ceylon Legislative Council, on the Forests Ordinance must shortly—on the 12th probably—be bringing their work to light, and, as this measure is one of peculiar interest to absentee colonists and capitalists looking to Ceylon, we may allow a correspondent to refer at some length to the subject. There is no doubt that the measure deserves the very careful consideration of planters and merchants, and this is the review of the situation sent to us :—

"Mr. Vincent's able and, considering his short visit to Ceylon on special duty, wonderfully exhaustive report has not so far commanded that general examination nor criticism that it demands in view of the scope of its proposals and the wide acceptance accorded to many of its propositions. The subject of forest conservation and growth is engaging systematic and scientific treatment all over the world, and is growingly recognized by the various Governments as one that can no longer be treated haphazard. In proportion as the conservation of the *future* as well as the *present* wellbeing of a community's material wealth—and forest land forms an important portion of its unexpended capital—is appreciated efforts are being made to obtain authoritative data on the subject, and to legislate thereon. All having the interest of Ceylon at heart will welcome any wise attempt to grapple with a question that eminently calls for investigation and control on such lines as may ultimately, after careful enquiry, be determined upon. Only good can follow well-considered efforts; only harm will ensue, and wrong be done, by hasty arbitrary action without sufficient knowledge, rough-shod riding to attain a goal that should only be gained by patient, laborious research, and honest straightforward regard for the special and in some respects absolutely unique requirements in connection with a Forest Ordinance for 'the Eden of the Eastern wave.' You have already published Mr, Vincent's Report, but both the draft Ordinance (clauses 83) and Mr. Vincent's report (130 pages) are so long that it is to be feared few have studied them. It is difficult to overestimate their importance if legislation on the subject is to be effective, comprehensive, progressive, not merely another dead-letter Ordinance placed on record by fitful caprice, irresolute, irresponsible statesmanship.

"It is to be regretted that the Burma Act should have been laid on the Council table almost verbatim, making it appear to those unacquainted with the fact that the Governor is responsible for this crude measure, had grasped the subject in a few months, and that the Draft Ordinance *is* the result of a careful study of the peculiar circumstances and requirements of Ceylon. The principle of the resolution unanimously carried by the Planters' Association should be insisted on in the interests of natives and of Europeans alike. The whole question is so large and so complicated in Ceylon that it would have required great tact, moderation and calm statesmanship to indicate the lines upon which legislation should be based—if justice is to be done to the interests involved immediately an Ordinance such as the Draft now being discussed becomes law.

"The principle of the bill as explained by the Hon. the Acting Colonial Secretary at the first reading is, that when, 'the conditions obtain in different provinces, power is given to Agents to make the rules, but, when the conditions vary, and when the matter is of greater importance, power is given to the Governor to make rules.' The Colonial Secretary further pointed out that the first chapter of the Ordinance related to reserved forests, and that it was somewhat different from our present law, *because it gives power to extinguish any private rights which might exist, when those rights will tend to affect the reserve of forest. Power is given to deal specially with the right* of way, and with the right of water-courses and pasture. These matters are dealt with in the first instance by Forest Officers from whom an appeal lies to the Government Agent of the Province, and, when all enquiries had been made, report was to be made to the Governor. The next chapter relates to Village Forests by which is meant forest reserves which are maintained for the benefit of every Village Community or group of Village Communities, and *power is given to define what rights they can demand*. A careful examination of the Draft Ordinance, however, shews that the explanations afforded by the Colonial Secretary are very superficial and are calculated to divert rather than concentrate attention on a proposed legislative enactment than which there are few of greater magnitude in the best interests of Ceylon. The subject is beset with difficulties the more it is examined that can only be satisfactorily overcome in time by great labour, under the direction of special officers, calm judgment, and *complete separation at all points of administrative and executive from judicial powers*, all of which will have to be exercised. The principle involved is fundamental, and it is satisfactory to know that Earl Derby has distinctly put his foot down regarding it. That it is too often practically ignored by the local Government does not lessen its paramount importance, nor absolve our legislators from recognizing it, on any specious plea, really fallacious.

SOME IMPORTANT PROVISIONS OF THE DRAFT ORDINANCE.

1. Its *local extent*. It extends to the *whole* colony.

2. Who is a forest officer ? All Government Agents and Assistant Government Agents, and persons appointed to discharge *any functions* of a forest officer under the Ordinance or any rules made thereunder.

3. *Forest produce* includes, among a variety of things found in a forest, *honey* ! &c.

4. Land at *the disposal of the Crown* means land in respect of which *no person has acquired the status of a landlord by grant, lease or prescription.* Nothing is said about those ancient valuable instruments specially recognised by Government, *sannas* ! &c., referred to by Mr. Vincent.

5. The Governor may constitute any land at the disposal of the Crown a reserved forest.

6. Whenever it is proposed to constitute any land a reserved forest, there shall be a notification in the *Gazette* (A) specifying the land, (B) declaring that it is proposed to constitute such land is reserved forest, and (C) appointing an officer hereinafter called the forest settlement officer to *enquire into and determine the existence, nature and extent of any rights claimed by or alleged to exist in favor of any person in or over any land comprized within such limits.* The officers appointed under clause (C) of this section shall ordinarily be a *Government Agent* or Assistant Government Agent, or some other person other than a forest officer.

7. After the notification in the *Gazette* abovementioned there shall be a proclamation by the forest settlement officer and among other things (D) fixing a period of not less than three months from the date of publishing such proclamation, and requiring every person claiming any right or making any claim referred to, to present to such officer within such period (viz. three months) a written notice specifying, or to appear before him and to state, the nature of such right or claim.

8. There next follows a *bar* of *accrual of forest rights*, that is, that, during the interval between the publication of the proclamation, and the date fixed by the notification declaring the forest to be reserved, no right shall be acquired in or over the land comprized in such notification except by a succession or

under a grant or contract in writing made or entered into by or on behalf of the Crown or some person in whom such right or power to create the same was vested when the proclamation was published.

9. Then follows *inquiry by forest settlement officer* who shall take down in writing all statements made under section 7 and shall enquire into all claims and the existence of any right in respect of which no claim is made &c.

10. The powers of forest settlement officers are those of a *Civil Court for compelling the attendance of witnesses and the productoin of documents!*

11. Power is given to the forest settlement officer to *acquire land over which right is claimed and to admit any claim wholly or in part.* If the claim is admitted wholly or in part the forest settlement officer may (1) come to an agreement with the claimants for the surrender of the right, or (2) exclude the land from the limits of the proposed forest, or (3) proceed to acquire such land in the manner provided by the *Land Requisition Ordinance* 1876; and as regards *right of way &c.* power is given to the forest settlement officer to *admit or reject* the same wholly or in part.

12. The forest settlement officer is empowered to *commute* any rights admitted to forest produce (*for instance honey*) by paying a sum of money in lieu thereof, or with consent of the claimant by grant of land or in such other manner as such officer thinks fit.

13. *An appeal* from the decision of the forest settlement officer *lies to the Government Agents of the provinces or Assistant Government Agents of the districts*, not as is essential to properly constituted judicial tribunals, viz., the District Court and Supreme Court, with ultimate appeal to the Privy Council if need be.

14. The conditions of this *appeal* to the *Government Agent* are, among others, after all lands (if any) to be included in the proposed forest, which the forest settlement officer has elected to acquire have become vested in the Crown.

15. *Rights*, in respect of which no claim has been preferred, and of the existence of which no knowledge has been acquired by enquiry under section 9, *shall thereupon be extinguished.*

16. *The Governor in Council may*, within certain limits, revise, rescind, or modify any order under this chapter *within five years* from date of proclamation.

17. No right of *any description* shall be acquired in or over a reserve forest, *except by succession or under a grant or contract in writing made by or on behalf of the Crown* or some person in whom such right or the power to create such right was vested when the notification under section 18 was published.

18. *Any forest officer may*, from time to time, with the previous sanction of the *Government Agent* or any officer duly authorized in that behalf *stop* any *public* or *private* way or water-course in *p* reserve forest provided that for the way or water-course so stopped *another way* or course, which in *the opinion of the Government Agent* is equally convenient, *already exists* or *has been provided* or *constructed by such forest officer.*

19. Certain acts are prohibited in reserved forests under the following penalties:—Imprisonment for a term which may extend to six months or with fine which may extend to five hundred rupees, or with both in addition to such compensation for damage done to the forest as the convicting court may direct to be paid.

20. There follows an extraordinary provision:—'The Governor may by notification in the *Gazette* direct that from a date fixed by such notification any forest or any portion thereof reserved under this Ordinance shall cease to be reserved; *but the rights* (if any) which have been *extinguished therein shall not revive* in consequence of such cessation.'

21. Next comes ante-dated confiscation without judicial enquiry:—'*Any forest which has been declared* a reserved forest under *any rules* in force *previous to the day on which this Ordinance comes into force shall be deemed to have been reserved hereunder*, and *all* questions decided, orders issued and records *prepared* in connection with the reservation of such forest *shall be deemed to have been decided, issued and prepared here under, &c.*' What special purpose (for such these must be) is intended by such an unfair un-British provision? Not surely to attempt to obtain the effect of *law* to proceedings taken!—*Ultra vires*?

22. The Governor in Council may prescribe for infringement of rules imprisonment for a term which may extend to six months or fine which may extend to five hundred rupees, or both.

23. Any forest officer empowered in that behalf may *compound forest* offences!

OF FOREST OFFCERS.

24. It shall be lawful for the Governor from time to time to appoint a Chief Conservator of Forests, and such other officers as are required for the purposes of this Ordinance, and there shall be paid to such Chief Conservator and officers such salaries as the Governor with the advice and consent of the Legislative Council may from time to time determine, Every Government Agent and Assistant Government Agent and every Conservator of Forests and every forest-officer authorized in writing under the hand of the Governor on that behalf shall posses, for the purposes of this Ordinance, the following powers (that is to say):—(*a*) *the powers of a civil court to compel she attendance of witnesses and the production of documents*; (*b*) *power to issue search-warrants under the Code of Criminal Procedure.*

25. Whenever it appears to the Governor that any *land* is required *for any of the purposes of this Ordinance, such land shall be deemed to be needed for a public purpose within the meaning of the Land Acquisition Ordinance* 1876, *section* 6."

THE COST OF TEA.

A correspondent writing from Foochow to the *Daily Telegraph* gives some particulars as to the cost of tea there, and "the duties it has to bear before getting into the consumer's tea-pot." If his object is to show that tea is not a legitimate object of taxation for revenue he is arguing to no purpose in the present state of the British Exchequer, which can certainly not dispense with the duty:—

There were 654,000 chests of Congou, weighing 69,760,000 lb. bought in Foochow during season 1883-84, average cost of which on this market was 15 taels per picul, or equal to 6¾d. per lb. This price includes all native commissions and profits, and is the actual cost to the shipper packed and ready for shipment. It also includes all native authorities' "squeezes" between place of production up country, and the shipper's warehouse. Now let us see what it costs the consumers in England if they can buy it on paying only 1d. per lb. profit, divided amongst the importer, dealer, and village grocer. The average cost as above, 15 taels per picul (133 lb.); duty paid here to Chinese Government, 2-8 taels, per picul (at exchange 5s. per tael)—17-80 taels per picul, £4 9s; freight on 133 lb., at £3 per ton (1d. per lb.), 11s. 1d.; commissions and charges, China and London, say 13 per cent., 11s. 10d.—£5 11s. 11d. (or laid down all charges in London warehouse at 10d. per lb); duty paid to British Government, 6d. per lb. on 133 lb., £3 6s. 6d.; profit, say 1d per lb. divided amongst importer, dealer, and grocer (the two latter probably get 6d per lb. profit), 11s. 1d.—£9 9s. 6d.; or a cost to the consumer of 1s. 5d. per lb. Should dealer and grocer get their regular profit, this crop, costing 6¾d in Foochow, is sold to consumer at 1s. 10d. per lb. It will be seen that the duty paid by the foreign shipper to the Chinese Government is over 18 per cent. on the actual cost, whilst the British Government charge a duty equal to 90 per cent. The value of tea in China and on the London tea market has declined enormously of late years but we doubt if the

consumer has ever felt the benefit. Low rubbishing stuff is bought here to lay down at 6d. to 7d. per pound in bond for mixing with Indian leaf. Apparently consumers are taken in by what is known as the 2s. canister, but those at home who have relations residing in China generally get their few packages direct, and say it is impossible to buy such tea in England. The best Congou can be laid down in London for 2s. 6d. per pound, duty paid, and if unmixed with Indian leaf nothing can beat it.—*L. and C. Express.*

COFFEE AND CINCHONA: REVIEW FOR 1884.

A DARK RETROSPECT REGARDING COFFEE—LARGE STOCKS—CAUSES OF LOW PRICES—SCARCITY OF GOLD AND OVER-PRODUCTION—ENORMOUS DELIVERIES FROM BRAZIL—BRAZILIAN SYNDICATES—THE FAILURE OF THE O. B. C. AND CEYLON COMPANY LIMITED—RISE AND FALL IN PRICES—COLORY COFFEES—CROPS IN JAVA, BRAZIL, &C.—IMPORTS OF CINCHONA BARKS—PRICES OF QUININE—GREAT INCREASE IN SUPPLIES OF BARK FROM CEYLON AND DIMINUTION OF THOSE FROM SOUTH AMERICA—BREAK UP OF THE QUININE SYNDICATE—FLUCTUATIONS IN PRICES—THE FUTURE OF BARK AND QUININE—PROSPECTS OF NEW AND OLD PRODUCTS IN CEYLON.

Coffee and cinchona are very lengthily reviewed by Messrs. Rucker & Bencraft as to the movements of those articles and their position in 1884. We need scarcely say that the retrospect is by no means cheerful, especially as regards coffee, the stocks of which at the end of the year were the largest on record, there having been a surplus stock for four consecutive years. The figures for European stocks at the beginning of this year were 186,050 tons. Scarcity of gold is suggested, in addition to over-production, as the cause of low prices, but we think over-production on the slave-cultivated lands of Brazil need alone be mentioned. The deliveries of coffee in 1883 having been "enormous," lowered stocks and better prices were expected, but the actual result in the first month of 1884 was very disappointing. To quote :—

During March a great fall was established in Coffee, and a great victory was won by the "bears" on the terminal markets. European stocks on the 1st of March were returned at 207,600 tons, showing an increase since January of 21,500 tons, and showing a surplus of 50,000 tons as compared with the previous year. The Brazilian syndicates found circumstances too strong for them, and their enemies naturally played a winning game with great confidence. To those, like ourselves, who only take an interest in Coffee from the planters' point of view, it cannot be a duty of a pleasurable character having to chronicle all these details regarding the transactions of speculators on the terminal markets. Terminal markets, however, exist, and it is impossible to write anything about Coffee without constantly referring to them. In the long run, no doubt the actual bean rules the market, but the influences of the terminal markets exaggerate and distort every natural movement.

The record for April is :—

Yet again a heavy increase in European stocks, 217,100 tons being now the figures recorded. Three months' bad trade, with rapidly falling prices, practically destroyed all hope for the more immediate future of the article. The deliveries for the three months had only been 78,400 tons against 127,400 tons in 1883, a fact which seemed altogether to knock on the head the hope that the heavy deliveries of 1883 would be maintained during 1884. The great success, which had attended the "bear" movement, was a complete surprise even to those who had started and nursed it, the statistical position having assumed a far more unfavourable appearance than had been anticipated. The failure of the Oriental Bank, and of the Ceylon Company increased the feeling of depression and the produce markets began to attract an amount of attention anything but pleasant, owing to the rapid fall in Sugar, Coffee and other articles,

In May there was a rally, and the deliveries were the heaviest during the whole year, while Rio coffee ceased to be sold at 8s. to 10s. per cwt. loss, and

Plantation Coffees, which had experienced a heart rending fall, middling Coffees being quoted at 61s to 65s, against 77s to 82s in January, became held with great firmness, and rose in value.

But prices again gave way. June was a dull flat month. Of July it is recorded :—

Early in the month another panic took place in Havre and 49 francs was quoted for good average Santos, against 71 francs at the beginning of the year. On the terminal market in Havre 10,656,000 bags good average Santos were said to have been turned over from July 1st, 1883, to June 30th, 1884. We reckoned this equal to about 12,787,000 cwt., and making the cost at 50s, we got the extraordinary figure of £31,967,500. In this month a large fire took place at New Crane Wharf, and about 1,800 tons of Coffee were destroyed. This produced a demand from the home trade, and Coffees suitable for that trade rose 3s to 4s in value.

Towards the end of the month markets hardened up a little, but prices were all lower than at the commencement. Good average Santos in Havre 50 francs.

AUGUST.—This month will be remembered as the month in which European stocks totalled 226,300 tons. Such a stock had never before been accumulated, and we very earnestly hope it may be many many years before it is so again. In December, 1882, Rio Coffees touched 28s c. & f. for ordinary firsts. In August, 1884, stocks were 225,300 tons. We believe both these dates will long be remembered by the Coffee trade. We hope that the events they chronicle will not occur again in this generation.

September was not much better :—

And with the exception of Plantation Coffees, (a trade now of almost a retail character) the end of the month saw quotations all lower. Good average Santos 49·50 francs.

OCTOBER.—A month of great depression, in which the quotations of Coffee were at about the lowest.

Middling Costa Rica	...50s	against 67s	at the commencement of the year
Middling Guatemala	...52s	„ 66s	„
Good ordinary foxy Guatemala	45s	„ 55s	„
Good Channel Rio	..40s	„ 56s 6d	„
Good average Santos in Havre	48 francs	„ 70 francs	„
Good ordinary Java in Holland	26¼ cents	„ 35½ cents	„

Importations kept steadily behind those of the previous year, but deliveries were also in the same ratio, so no progress was made as regards stocks.

In Europe and the United States, during the nine months, 80,000 tons less Coffee had been imported as compared with 1883, and yet stocks in the two countries were 23,740 tons, against 234,287 tons at the same time in 1883. Our European stock alone was equal to 5 to 6 months' consumption, the current Rio crop continued to give heavier receipts than had been expected, and a promise of a large 1885-86 crop was generally expected. Only those who follow the article closely can realize how excessively disappointing the course taken by European stocks has been, and though probably much sound work has been done behind the scenes, still so little palpable effect, after so many months, has upset all calculations. Good average Santos in Havre 48 francs.

November gave somewhat better results, but December was a very disappointing month :—

In the first place as regards the current Rio crop, it is generally allowed that 3,500,000 bags will be shipped at the least, this being the maximum estimate put forward originally by our friends. One large house talks of 3,750,000 bags export. Santos, instead of given 2,000,000 bags, will now probably give an export hardly greater than last year, say about 1,900,000 bags.

The following quotations show roughly the result of the year's work :—

Fine middling Plantation Ceylon ..	78s to 84s	against 87s	to 90s.
Middling „ ..	65s to 68s	„ 77s	to 82s.
„ Costa Rica ..	53s	„ 67s	
„ Guatemala .	54s	„ 66s	
Good ordinary foxey Guatemala ..	48s	„ 55s	
Good Channel Rio, c & f.	41s 9d	„ 56s 6d	
Good average Santos in Havre	52 francs	„ 70 frc.	
Good ordinary Java in Holland	28 cents	„ 35½ ct.	

At the present moment our stock in Europe is about 140 per cent. larger than it was five years ago, viz., say 190 000 tons against 80,000 tons.

Colonry Coffees.—These Coffees must now practically be divided into two classes. Owing to the ravages of the leaf-disease, only a small portion of the Ceylon crop now comes to market as fine Coffee. A large proportion of the crop, therefore, is of middling quality, and moves with and is guided by the same class of Coffee from countries such as Costa Rica, Guatemala, Venezuela, Honduras, &c., &c. The same applies to East Indian Coffees, the quality of which, in a large proportion of cases, has been poor both in size and colour. Such Coffee as we have already said has come back to, and travels with Coffee generally. Java, where we are sorry to say we hear that the leaf disease is spreading in some quarters with alarming strides, sends still to Europe large and taking Plantation Coffee. but it has lost some of its popularity, owing to the fact that in many cases the colour has paled off almost entirely.

Really fine coloury Coffees, with size, and appearance no matter where they come from command still good rates. The supplies of middling Plantation Coffees have, however, vastly increased, and the quality of middling Plantation Coffees from Ceylon and India has greatly deteriorated, both in size and colour. We, therefore, say that these crops can no longer be treated as fancy crops, a statement which is corroborated by the course of prices. But for fine Coffees, such as Ceylon used to export in quantity years ago, we maintain there is still a good market.

Notwithstanding this adverse state of things, fancy Coffees are now as dear as they were a year ago, if not dearer; thirdly, a fine and well known mark of Honduras Coffee has all through the year sold from 90s upwards, and we maintain that the low average in prices now existing for Plantation Ceylon and East India Coffees, is at all events as much owing to the said falling off in quality, as to the adverse run of the market for Coffee generally.

The Java crop, which was equal to 1,569,000 piculs in 1879-80, is taken at only 1,400,000 in 1883-84, while the estimate for the following season is 1,281,000. The picul is only about 21 lb. more than the cwt., so that even Java counts but little in the world's sources of coffee when compared with the overwhelming produce of Brazil. The figures for three years are :—

	Rio.	Santos,	
1882-83 ..	265,291	108,668 =	373,959 tons.
1883-84 ..	177,692	112,330 =	290,022 ,,
1884-85 estimate	206,000	112,000 =	318,000 ,,

Multiplied by 20 the crop of 1882-83 gave the enormous result of 7,479,180, or sevenfold the largest yearly export from Ceylon. To quote again :—

The crop in Porto Rico is much larger than that of last year and is estimated at 24,000 tons. Haiti will also give a large crop. Guatemala, Nicaragua, Honduras, and Venezuela are all expected to give crops much the same as last year. San Salvador will give a slightly larger yield, say 10 per cent. whilst in Costa Rica the crop will only be about two-thirds of the one just over. The future seems as usual to depend almost entirely on the course of receipts in Rio and Santos, and if these be in accordance with general expectation, under ordinary circumstances Coffee should be an article slowly, but steadily, gaining ground. If any sudden and general revival in trade were to take place, of which at present there are no signs. Coffee would no doubt participate, but the stocks are too heavy to allow of any great liberties being taken with the berry. To sum up, the amount of Coffee at the disposal of the trade in Europe and the States promises to be, if anything, slightly larger during 1885 than during 1884, but it is hoped that the comparatively poor deliveries of 1884 may be improved on, and that stocks may be decreased.

Of Cinchona Bark the report is :—

During 1884 our imports have been 59,287 packages, against 90,608 in 1883; 110,517 in 1882, and our deliveries 78,532 packages, against 67,350 in 1883; 88,717 in 1882; our stock, therefore, has decreased, and was on the 31st of December 80,500 packages, against 99,667 in 1883; 70,676 in 1882.

Howard's Quinine is current at 4s 8d and 4s 5d, against 8s and 7s 9d in January 1884, against 8s and 7s 9d in January 1883, against 10s and 9s 8d in January 1882.

We quote the East India unit today at 6d to 6½d, against 6d to 7d in January 1884, 11d in January 1883, 1s 6d in January 1882.

The principal features of the Bark trade during 1884 were the great diminution in supplies from South America, the great increase in supplies from Ceylon, the break up of the manufacturers' syndicate for sustaining the price of Quinine, the failure of the Milan factory, and the break up of the old speculation for the rise.

At the Bark sales on the 12th August the unit was down to 5½d to 6d, and Howard's prices 4s 6d and 4s 3d. Towards the end of the month 4s 9d and 4s 6d were again quoted for Howard's Quinine, but Bark could not rally. There is no reason for us to refer to, or to discuss the ramifications arising out of the Milan Factory failure, suffice it to say that they gave the Bark market a great shake. The unit fell away in September to 4d to 4½d, but as the old houses in the South American trade now virtually took their Barks altogether off the market, some relief was experienced. Early in October Howard's dropped their price to 4s 6d and 4s 3d. East Indian Bark, however, improved, chiefly owing to the strong policy maintained in the handling of South American Barks. A quiet month, however, on the whole, with Quinine down to 4s 3d and 4s towards the end.

We suppose 4s. is the lowest figure at which Howard's quinine has ever been sold. The review goes on :—

With lighter sales all through November, Bark improved and towards the end of the month a good demand set in for Quinine. Improving markets both for Quinine and Bark carried us on to the end of the year, Howard's Quinine at the moment of writing being quoted at 4s 8d and 4s 5d, the East Indian unit at 6d to 6½d. The future of Bark is still wrapped in obscurity, as the course of the market depends greatly on the action of those who really control and hold the stocks, also because the prospects of supplies are uncertain. We however pin our faith to Quinine as a Drug, we believe in time the consumption of Quinine either in a manufactured or in its natural state, probably in both, will be greatly extended, and to those who can grow good Barks we unhesitatingly say persevere.

It will thus be seen that in 1884 the prices of coffee did not atone for lessened yield, while cinchona was largely smothered by its own weight. If low prices always lead to increased consumption and demand, there are no doubt better days in store for both coffee and cinchona bark, in the case of those who are able to cultivate them, without fear of leaf-disease, bug, grub, or canker. The hopes of Ceylon are now generally centring in tea; cacao and cardamoms being good subsidiaries. In what a different tone are we compelled to talk of poor old coffee to that which prevailed at the commencement of 1875. All then looked bright and hopeful, the fungus being regarded as but a temporary evil. Alas for human hopes and foresight. But we can only fight on and do our best, still cherishing hope of final success.

NORTH BORNEO:

The Chairman on the Prospects of the Company.

According to the Report of the fourth half-yearly meeting of the British North Borneo Company, on the 17th December 1884, Sir Rutherford Alcock, K. C. B., (Chairman of the Company) said :—I need not refer in any detail to what must be known to most of you here; how seriously the disturbed state of affairs in the East, owing greatly to the intermittent hostilities of the French and the Chinese, has affected all operations of trade, and all Colonial or Commercial undertakings, not only in China, but in all the colonies. As far, indeed, as Australia and India its influence is felt. We who are the youngest of the colonies, and are yet, so to speak, in our infancy, could not hope to escape from depressing influences which this state of affairs has brought to bear upon all undertakings. I am glad to be able to say, however, that I have really very little or nothing to

tell you which will not, I think, be satisfactory to you to hear. (Hear, hear.) Considering the adverse circumstances under which we have to make our progress, I think it will be satisfactory to you to hear that our revenue goes on increasing continuously (hear, hear,) and we see now, having had the third quarter's return, and that in all probablity the revenue for this year will exceed that of last year by at least 30 per cent. In our expenditure also, means have been found of making sundry economies; and although it will be necessary to pass special votes for some new appointments and make a further outlay of capital in buildings, more especially a gaol, a Government house at Elopura, the headquarters, and barracks for the police at that settlement, which cannot any longer be deferred, those will be entirely covered, so that there will in reality be no increase of expenditure on that account in the year's budget. That is the general result; and now in reference to our prospects. I think I shall be able to show you that they are very promising, and that there is nothing even in the adverse circumstances, which affect us in common with all the rest of the Eastern world, that should in the least degree tend to discourage us in the great undertaking we have in hand.

As to our general progress, I will read you a short extract from the Governor's dispatch covering the estimates lately received, and I prefer to give you what our own officers send us, because it shows it is not only our supposition or inference, but really what those on the spot report to us. The Governor remarks:—"It has been very nearly conclusively proved that Borneo is a tobacco growing country, and in this one culture alone lies the possibility, I may almost say the probability, of a sudden and rapid development of our resources, involving a large increase in the revenue from land sales, farms and other sources. The Chinese Sabah Company will, at the commencement of the year, ship at least 9 tons of tobacco to Europe, and should the price obtained approach as we have reason to believe it will, that of Sumatra grown leaf, the attention of tobacco planters will be turned to North Borneo, it being currently reported that land suited for tobacco growing is becoming scarce in Deli, where such enormous profits have of late been made by planting Companies; indeed Mr. W. H. Read tells me that it is not improbable that 125 per cent dividends, will this season, be declared by some of them. That Liberian coffee, cocoa and sugar cane will do well here is also, I think, put beyond all doubt."

You are aware it is not on the finding of minerals or gold that we have ever built our hopes. We have always looked to agriculture, and to the cultivation of land, as the best and most permanent source of the prosperity of the colony. (Hear, hear.) We still maintain that opinion, and you know the policy of the Company, (which has been clearly put forward, and always had your full approval), has been, that the shareholders should not propose to enter into competition with the capitalists outside who might be disposed to invest their money. All we have done is to give them facilities, and assistance when it was in our power to do so, to offer them security for their persons and property, and freedom from interference in their operations; and I believe we shall be repaid by seeing an increasing community, planting not only tobacco, but numerous other products. We know this wave of depression has overtaken sugar in Australia and elsewhere; sugar and sago have fallen to unprecedently low prices. Of course that deters planters from putting their money into new ground for these products. Someone has said, and said very truly, that to build up a new colony two things are essential, Time and Capital, and we must give a reasonable time for development.

COFFEE AND TEA ON THE WYNAAD, SOUTH INDIA.

VYTHERY, Jan. 25th.—The coffee sample appears to be unusually good this season, and the yield on most Wynaad estates is above the estimate, so if the market will only keep firm for a few months a good many planters will be able to pull along better than they could have hoped to do a short time back. A curious feature in connection with prices is the fact that, while not willing to go much above R32 for parchment, one or two firms are offering R28 per cwt. for cherry, and are buying a good deal at this rate. There is still a good deal of talk about tea, and there is a prospect of its being opened to some extent in South East Wynaad. There can be no doubt that tea will do well in this district, but with advances cut down to about R25 per cwt. few men have money enough to try experiments, and prefer to struggle on with their coffee. In spite of the dictum of the *Ceylon Observer*, in the article you recently quoted with reference to one of my letters, I do not see how small estates of 50 acres can pay for the machinery. It may perhaps be intended to bring all the leaf to a central factory, but I cannot hear that even then there is much chance of working the yield to "8 and even 10 maunds per acre" (640 lb. to 800 lb. *) and though in one exceptional case this limit has been reached, and even passed in Ceylon, it does not at all represent the average. In the north I believe 4 to 5 maunds per acre is looked upon as a handsome return; and the experience of planters there stretching as it does over so many years, is probably the more trustworthy of the two. On a large acreage, however, it does not require 800 lb. nor even 400 lb. per acre to make the industry pay. We have not yet heard what prices were realized for the "Mariawatte" tea but from the fact that they put off their pruning so long it would appear as if they must have plucked rather coarsely. In the Nilgiris the yield is comparatively small, but this is made up for in quality.

The property of the Wynaad Gold Mines Company was put up to auction in Bombay on the 12th. The bidding went up to R4,000, but the proprietors finally bought the estate in. The property consists of about 1,700 acres of land, of which about 200 have been planted with coffee and cinchona. As there is, I understand, a fair crop on the place, which would go to the purchaser, the price offered was very low, and this may be attributed to the state of uncertainty that all landholders in Wynaad are now in, and are likely to remain in for some years. I have not heard if the Company intend to do anything with their reserve acreage. A good deal of money was spent in working at the reefs in the mining days, and machinery was purchased in Australia for crushing the quartz, but was never worked, nor even, I believe, sent up to Wynaad. The other mining Companies are giving no particular sign of their existence, and the new system of extracting gold does not seem to have been found practically useful.

The sale of the Wynaad Gold Mining Company's property, which had to be bought in, and the sale of 200 acres of abandoned coffee land in Ceylon for R20,000, are cases in point. Probably the Wynaad property is just as suitable for tea as the other, and the unwillingness of buyers to come forward must be attributed to the course Government is now taking.—*Madras Mail.*

THE NEW ORLEANS WORLD'S EXPOSITION.

INTERVIEW WITH THE COMMISSIONER OF GUATEMALA, MR. FORSYTH [FORMERLY OF CEYLON].

GUATEMALA.

This enterprising and influential State, the principal of the Central American group, containing a population of 1,500,000, wisely determined to place her marvellous resources and attractions before the eyes of the world, realizing the signal opportunity of occupying her proper position in the world's congress that will soon convene at the World's Industrial and Cotton Centennial Exposition.

This State is ably represented by the accomplished gentleman, W. F. Forsyth, Esq., one eminently fitted for so responsible a position. He, on being interviewed by a *Times-Democrat* reporter, gave the following description of the exhibits of Guatemala here and en route.

* We gave this as the experience of a North Indian planter, who, by confining his gardens to 50 acres of well selected soil, &c., raised his average to from 640 to 800 lb.; we by no means said such an average could be established all over Ceylon or Wynaad.—ED.

Mr. Forsyth has brought 109 cases, containing exhibits of thirty three varieties of the natural products of the Republic of Guatemala, such as samples of coffee, cotton and cocoa: various kinds of maize, wools, minerals, timbers, etc. The samples of cotton have been selected from fields, ranging from 500 feet to 6,000 feet above the level of the sea. The samples of sugar cane were cut from fields of similar altitudes.

THE COFFEE EXHIBITS

consist of samples of coffee grown on elevations ranging from 1,000 feet to 5,000 feet, which latter is the extreme height on which coffee can be produced in this republic. The export of coffee per year from this State amounts to nearly 400,000 quintals.

The Guatemalian exhibit will occupy a portion of the space of the Main Building located near the centre of the southern end and adjoins the space allotted to Mexico, giving an area of 1,440 square feet. On this space there will be erected two pyramids, each surrounded by counters three feet in width, containing cases in which will be placed the sample of the various products of the country, including specimens of timbers, cereals, textile fibres, coffee, cocoa. The two divisions of the space will be connected by a pagoda, which will be decorated with the orchids, flowers and plants of the country. One of the pyramids will be finished by the coat-of-arms of the republic on each side, with a large photograph of Gen. Rufino Barrios, his Excellency the President of the republic, one of the foremost reformers of Latin-America. The opposite side of the pyramid will be a circular plate of solid silver—777 ounces—from the Mataescuintla mine, the property of the President.

On the other pyramid will be shown, surrounded by glass, the foods of the people tastefully arranged. The *tout ensemble* of this display will be unique and elegant.

In addition to the above display there will be in the Horticultural Hall one of the largest and most beautiful exhibits of orchids ever collected, numbering over 6,000 plants, embracing about fifty varieties. Many of these will be blooming during the next sixty days. Some of the rarest of these will form the contribution of the Republic of Guatemala to the State of Louisiana. These eighty cases of plants are due per steamship "Craigallion."

The Board of Commissioners of the exhibit of Guatemala consists of W. J. Forsyth, Esq., and Emilliano Martinez, consul of Guatemala.

The exhibit of minerals will embrace various specimens of gold, silver and copper ores from several mines, which have been worked by the natives for many years, and are still rich.

In addition to the above the collection of superior marble and building stones will surprize many unacquainted with the undeveloped possibilities of this republic.—*New Orleans Times-Democrat.*

THE CRY IS STILL THEY COME.—The latest concern floated, or *trying* to be floated, is "The Rhea Cultivation and Land Company Limited," which proposes to include in the sphere of its benevolent intentions, tea. We append the statement of "Objects and Reasons." It is the richest thing of the kind we have seen for some time,—especially the *elsewhere*. *Object* to cultivate rhea, coffee, tea, &c., in India and elsewhere. Capital £10,000 divided into 10,000 shares of £1 each. Registered by Pike & Minchin, 2, Metal Exchange Buildings, E. C. The first subscribers are:—Charles Fox, clerk, 33, Crane-grove, Highbury, N., 1 share; Samuel J. Hewlett, clerk, 18, Pomona-place, Fulham, S. W., 1; Daniel von Olegar, merchant, 25, Emperor's-gate, S. W., 1; William Pottinger Daniel, 20, Granville-square, W. C., 1; Louis Francatille, clerk, 35, Holland-street, Clapham, S. W., 1; Michael Henry Isaacs, merchant, 84, Lombard-street, E. C., 1; Richard Wm. Otto Roehs, 39, Lombard-street, E. C., 1 share. Registered without articles of association.—*Indian Tea Gazette.*

THE CEYLON COFFEE PLANTATIONS have been suffering from grubs. These turn out to be allied to those of our English cockchafer. The planters want to know, of course, how to get rid of them, and have applied to Mr. R. M'Lachlan, F. R. S., one of our most distinguished entomologists, who thinks dilute kerosene oil might do for them, but advises the encouragement of insectivorous birds above all things, stating that a flock of crows would probably destroy more grubs in an hour than would be possible by artificial means in a week.—Dr. Taylor in "Science Notes" in *Argus.*

AUSTRALIAN TEA MARKET.—This shows decided improvement. By mail advices from Melbourne we learn that the cargoes of the "Bucephalus" and "Newcomen" were all taken up at excessive rates,—considerably overruling rates in London. A fire which took place at one of the Bonded Stores destroyed some 200,000 lb. weight of tea. This may have had some effect on prices; but still it is clear that Indian tea is steadily growing into favour. Stocks of tea in Melbourne and Sydney are rather heavy just now, and the market must be therefore fed with caution; but of the ultimate triumph of Indian tea in the Australian colonies, there is little doubt.—*Indian Tea Gazette.*

SCIENCE AND PRACTICE.—We have received from the Indian Tea Association a little pamphlet on the remarkable influence exercised by the *Sau* trees on "the tea bush." In future issue we hope to be able to notice it at length, but in the mean time we may be permitted to say that the pamphlet bears out most fully what we have for some time been endeavouring to impress on the Tea Association and all interested in the great planting industries of India, namely, that the time has come when scientific experts with a practical knowledge of the various planting operations should be engaged to do for tea, indigo, coffee, &c., with British Farmers' Associations and Societies have found it profitable to do, that is, join science to practice.—*Indian Planters' Gazette.*

COFFEE.—I am afraid the evolution of morality is by no means *pari passu* with that of intelligence; otherwise why does commerce daily find it getting harder to do right than wrong? Nay, it would even appear as if went out of our way to do wrong when it would be easier and cheaper to do right. I am reminded of this by the fact that recent statistics concerning the importation of coffee into the United States show that, out of 440 millions of pounds, 360 millions, or nearly five-sixths, is of American growth. But American-grown coffee is often called "Mocha," and to keep up the farce it is actually sent to Arabia, in order that it may reach the United States from the latter country as "Mocha coffee." It is now stated that out of 4,535,040lb. of coffee sold as genuine and indisputable "Mocha" (on account of its having made the voyage to Arabia and back) not more than 2½ millions is what it professes to be.—Dr. Taylor in *Argus.*

HELP FOR SUGAR PLANTERS.—The Government of Sir J. Pope Hennessy is behaving well according to a correspondent of the *Natal Mercury*:—At the last sitting of the Council of Government the Government announced that the export duty of seven farthings imposed on every 100 kilos. of sugar levied to meet the expense of re-wooding the uplands, will be withdrawn from the 1st January next. Port charges are also to be reduced by 50 per cent. in order to induce ships to come here. His Excellency leaves to the Council to decide whether the 30 cents. of a rupee levied on every 100 kilos. of sugar exported, should not be abolished in presence of the present commercial crisis which the colony is the prey of. And finally a draft ordinance is before Council of Government to exempt from Customs duties vacoa and other bags imported into the colony for the packing of sugar. These reductions are calculated to reduce the bag of sugar by fully a shilling. This is a good deal when spread over a large consignment of sugar.

Italian Coffee.—We have the authority of the Manchester (England) *Guardian* for the statement that "coffee planting is being tried in the neighbourhood of Rome. Signor Antonnicola has of late years cultivated the berry at his country estate, the Villa Cesisa, the result being 2,000 kilos to the hectare, valued at £80. The cost being £12 per hectare, he has cleared £68 per hectare profit."—*American Grocer.*

Ceylon Tea at Home.—On a new sample of tea roughly prepared, sent home to him, an old Ceylon coffee planter ("P. M.") writes as follows:—"It arrived safely and in excellent order, as crisp as if out of a sirocco and of exquisite flavour. If we can export tea like that, I feel sure it will do well. The liquor was of a pretty amber colour and strong. To do it justice we used the same quantity as of the tea we were using, but that was too much. We found the best quantity to be one-third less than that, which of itself would be a good saving besides the superiority of the beverage."

Lyle's Improved Patent Tea Roller.—In the interests of our tea planting friends, it may be useful to draw attention to a further improvement just registered in this roller, which has already much to recommend it. Of course where there are so many rollers in the market each has its special votaries; but judging from the testimonials given by some of the largest concerns in Assam and Cachar, this roller is certainly not behind the rest in public favour. While it is the cheapest in the market and the most difficult to get out of order, it is certified to be invaluable for rolling badly withered leaf, and of vastly improving old leaf. The complaint that some planters had of the difficulty of replacing its worn out interior battens or ribs has been entirely remedied by substituting substantial solid beech wood sections for the barrel, which all fit into each other and are fixed in grooves, and can be changed in a few moments. All screws and projections are entirely avoided, thus rendering it almost impossible to tear the bags, which consequently will not last much longer. We understand that spare parts are available, and the old machines can be fitted with the improvements at small cost. The machine secured a 2nd class diploma and medal at our late exhibition before the present alterations were effected, and it is probable now, therefore, that with its recent improvements, it will rapidly increase in the public favour. The Agents are Planters' Stores and Agency Co., Ltd.—*Indian Planters' Gazette.*

Slavery in Brazil.—There is a considerable number of politicians and voters which claims that the Rio Branco law is amply sufficient to meet the emancipation question, and that by a strict compliance with its provisions, conflicts will be avoided and the movement be steady and allow of time for substituting free labor for the slaves. Let us see how the district of Cantagallo, province of Rio de Janeiro answers these statesmen. On the 24th ulto. the minister of agriculture ordered the payment of $34,650 for the emancipation of 30 slaves, freed in that district for account of the emancipation fund. The average is $1,155 per slave, a price so utterly preposterous that we can hardly bring ourselves to believe that Sr. Carneiro da Rocha signed such an order. The daily press are constantly publishing the cost to the fund of freeing slaves in other provinces and never has the cost been anywhere like the amount paid to the fortunate slave holders of Cantagallo. The planters have refuted the arguments of their own party, that the Rio Branco law will emancipate Brazil. Death may release the bonds of the slaves, but at $1,155 for each slave certainly the emancipation fund never will; and if Cantagallo estimates the value of its slaves at this scandalous price, why should not the other provinces do likewise? The planters of Cantagallo who demanded, and the government which paid. $1,155 for the freedom of each slave, have a heavy account to settle morally and we sincerely trust that Sr. Carneiro da Rocha may be called upon for some explanation of a matter, so nearly approaching a scandal.—*Rio News.*

The *T. A.* in England.—A correspondent sends us a cutting from the *Field* of Dec. 13th containing the following recommendation in a "Notice to Correspondents":—

We should strongly advise you to get Ferguson's "Tropical Agriculturist," published monthly at Colombo (London Agents, Haddon & Co., 3, Bouverie-street), and costing £1 6s per annum. The fourth volume is in progress, and every number contains useful hints and information on all the Sinhalese industries.

The Central Factory System.—The Barbados Agricultural Society has sent out another circular addressed to the proprietary body and others interested in the welfare of the island, in which a committee appointed by the society to receive and consider suggestions for action in view of the evils which threaten the Colony, reiterate their conviction that the Usine or Central Factory system is the most practical means of rendering the manufacture of sugar profitable, and thereby averting ruin; and it calls upon them to consider the resolutions, which the society hopes will meet with hearty support. A loan of 750,000*l.* will be required to carry out the scheme, and it is suggested that application be made to the British Government for the necessary assistance, either in the shape of a direct loan, or a guarantee in raising in the English market the required sum.—*Colonies and India.*

A Profitable Pitch Lake.—A correspondent, writing to a Trinidad contemporary, says:—"You have recently, and I think, most opportunely, called the attention of the public of Trinidad to the unsatisfactory working of the Pitch Lake leases in relation to the Government, and the extracts from official documents lately published by you are highly interesting and instructive. It seems that except five acres reserved by the Crown, the whole of the lake is practically in the hands of three individuals at an annual rental of only about 260*l.* Last year the exports were 4,868 tons of boiled, and 34,277 tons of raw asphalt, the duty on which was about 1,100*l.*, the Government thus receiving about 1,360*l.* only. It is no secret that the lessees now form a 'ring,' and have put up the price so as to give an enormous profit to themselves, with the natural tendency, by restricting its use, of checking the growing increase in the exports. The expense of digging and shipping is under 8s or $2 per ton, freight to Europe 20s. and to the United States $3, and selling price there 40s to 45s, and $12 here, leaving a certain profit of $3 per ton—or say $120,000 per annum to be divided between a few individuals, not one of whom can be said to have any substantial stake in the island beyond what they thus get out of it."—*Colonies and India.*

Coffee in Coorg.—The coffee enterprize in Coorg is at present passing through the most critical stage in its existence. But while in other parts of Coorg its cultivation has been more or less a failure resulting in heavy loss of the capital, the good management, judicious expenditure, and well directed efforts of planters, based upon the experience gained in the past, have resulted in securing most satisfactory results in that recently opened tract of country in south Coorg, known as the "Bamboo." There, and on the Suntikoppa side of the Mercara plateau, are to be seen fine sheets of coffee extending for miles together. The secret of success has consisted in the early propagation of suitable shade trees as a protection against the numerous enemies of the plant, and in the pursuance from the commencement of a system of high cultivation. With the fine crop which was picked last year, the largest yet known, it was confidently expected that the labour given and the outlay incurred, would at length be repaid by handsome profits; but the result has been only a disappointment; for the heavy fall of 40 per cent in the price of the berry has upset all calculations, leaving little or no margin for profit. The result is that banks and agents refuse to make advances on the crop, and that estates are generally unsaleable. This is a great discouragement to the European gentlemen, fully 200 in number, who have taken to the cultivation of coffee in Coorg as a means of livelihood, and also to the numerous Natives who have been induced to embark in the enterprize, and who often, from no fault of their own, now find themselves in very embarrassed circumstances.—*Bangalore Post.*

THE YIELD OF TEA FROM AND AVERAGE PRICE OBTAINED BY TEA ESTATES.

(From the local "Times.")

The publication of the yield of certain estates has naturally aroused a feeling of curiosity, not easily allayed, except by the affirmation or denial of the superintendent concerned. On the whole, however, a knowledge of what different estates have actually yielded cannot but be of benefit to all interested in the enterprize. The manager of Aberdeen estate has been called upon a number of times to inform the public of the truth or otherwise of the enormous yield attributed originally to that estate during the past year, but as yet without drawing any statement from him, though we are not without hopes that he will come forward shortly with full particulars of the yield of the estate of which he has charge. The question of quantity per acre is so bound up (as we have often remarked before) in that of the average price obtained, that it is impossible to dissociate them. A statement, therefore, of the amount obtained per acre from a given estate is practically useless unless the average price obtained is also given. In two notable instances these particulars have been given in a perfectly straightforward manner, namely, in the cases of Mariawatte and Abbotsford. The value of these statistics is more than ever apparent when we remember the widely-different conditions obtaining with each—the one situated at an altitude of some 1,600 feet, the other at nearly 4,000 feet higher elevation. In both cases the average was good last year, Mariawatte obtaining 1s 2½d, we believe, and Abbotsford 1s 2d.

TEA ESTATE YIELDS IN CEYLON.

After deducting freight, insurance and selling charges from the price realized for Aberdeen, 1,100 packages we are left with a net result of 45 cents in Ceylon. I think I will be close on the mark if I take 35 cents. as the price at which it is put f.o.b. Colombo, but the Superintendent can put this right if it is too low a figure. This would give a profit of 10 cts. per lb. or R100 per acre on a crop of 1,000 lb. per acre. Now, if a planter is satisfied with R100 per acre, would it not be better to pluck finer at the rate of 330 lb. per acre and get the "Ceylon average" of 1s 3d? This would give him R100 per acre profit, and I need not point out whether it would be advisable to pluck 330 or 1,000 lb. if you knew you were to get the same profit at the end.

Mariawatte, another heavy yielding estate, of over 1,000 lb. an acre, certainly shows a different picture. I find its average nett in Ceylon from Messrs. G. White's figures, after deducting 9 cents for the usual charges to be 65 cents, and I am informed on good authority that its teas are placed f.o.b. Colombo at 30 cents per lb., thus giving a profit of 35 cents per lb. or R350 per acre.

Abbotsford, from the statement made public by its proprietor the other day, shows a yield of 506 lb. per acre, and Messrs. G. White's circular shows sales for 467 packages for the year averaging 1s 2d which gives 61 cents nett in Ceylon, and assuming the tea costs 35 cents f.o.b. Colombo, we have a profit of 26 cents per lb or R131 per acre.

I write this to point out to those who merely look on the surface of statements that two estates giving each at the rate of 1,000 lb. per acre may show quite different results in the way of profits. In fact, I think it is pretty evident from the figures I have given above, that Mariawatte gives 3 times the profit per acre that Aberdeen does, notwithstanding the similarity in yield. I would also note the fact which makes the difference more astounding that Mariawatte has only half the number of plants per acre that Aberdeen has. HUM KO MALUM.

THE "TROPICAL AGRICULTURIST."—An Indian planter writes regarding the *T. A.* :—"No planter should be without the magazine: certainly I can't do without it. Only yesterday I was puzzling over a question, but, as soon as I opened the pages of the *Tropical*, I found my answer."

CINCHONA AND THE DEVALA MOYAR COMPANY.—The accounts of this Company show a profit on the year's working of £591. The cultivation expenses of coffee and cinchona amount to £2,735. The proceeds of the coffee crop were £1,766, of cinchona £1,113. Dividends on investments and interest were £2,476. The report states that the time had not yet come when they could arrive at a decision as to the real value of the Company's mining property. The Directors cannot advise as yet abandoning the mining enterprize, involving, as it would, the total loss of the capital expended; and they propose continuing to push on the works with vigour. The cinchona trees were being increased in number; the nurseries also were in a flourishing condition. The possibility of profitably cultivating rhea and other grasses is continuing to have the Directors' attention; but the time has not yet arrived, in their opinion, for taking positive action. The proposed agreement with the Rhodes Reef Gold Mining Company has been made, and the liquidation of that Company is proceeding in the manner contemplated.—*Madras Mail*.

CEYLON TEAS IN LONDON.—A gentleman of some experience in the tea trade writes to us by this mail:—"I have read the Nov. and Dec. numbers of the *Tropical Agriculturist* with much interest, and beg to thank you for affording me the opportunity of becoming acquainted with the valuable information contained in them. The description of the new Tea Factory on the KAW estate (although this estate has not produced any exceptionally fine teas) would appear to indicate that everything is there provided which could possibly contribute to success in the manufacture of good and useful teas. A fair quantity of Ceylon tea has been offered during this week, and has sold readily at firm rates, some good invoices from he Rookwood, Blackstone and Ardross estates commanding very good prices. A friend of mine, a large tea dealer here, gives me his opinion that the teas from the following estates are mostly liked by the trade:—Gallebodde, Loolcondura, Rookwood, Adam's Peak and Yellangowry; the teas from Mariawatte fairly; those from Loolcondura and Abbotsford being much appreciated by the dealers."

CLOSE PLANTING OF TEA IN THE LOWCOUNTRY was recently thus advocated in the local "Times":—"A great change seems to have come over local ideas regarding the best distance to plant tea in the low-country. When the enterprize was in its infancy of all sorts of planting was gone in for, 5×6 and sometimes even wider being quite usual. Now 3½×3½ or 3×3½ is by common consent considered to be the best distance to adopt, the great object to be aimed at being to cover the ground as quickly as possible. As it would be impossible in the low-country to allow the trees to run up to any height, as is done on estates at a high altitude, it is very necessary that the trees should be planted as closely as possible without injuring the healthy growth of each tree, in order that the burning rays of the sun may be kept as much as possible from the ground. Unless this is done it stands to reason that years and years of sun and rain pouring down on the soil must have a prejudicial effect upon it, particularly when the altitude and heavy rainfall are both taken into consideration. This being now thoroughly understood, almost all clearings are being planted at one or other of the two distances mentioned above, 3 ft.×3½ or 3½×3½, while it is a question whether as close a distance as 3×3 might not be adopted with safety."—On returning from a visit to Darjiling in 1876, we advocated so close planting as 3×3 for very high estates, but the unexpected luxuriance of growth at lofty altitudes has led us to modify our opinion, and we would now recommend nothing closer than 3×4 or perhaps better 4×4. Room must be left for the pluckers and the forkers. No doubt, it is very desirable on low-country estates to get the ground shaded as speedily and as much as possible to prevent the destructive process of combustion of the soil. But on low-country estates as on high, room must be allowed for cultivating and harvesting coolies. Perhaps this Indian discussion as to the merits of *Albizzia stipulata* may help to solve the difficulty. Let the tea plants be put in 4×4, and Albizzias put out simultaneously at the rate of about 100 to the acre?

CEYLON UPCOUNTRY PLANTING REPORT.

GOOD YIELD FROM YOUNG COFFEE—CACAO AND ITS ENEMIES: JUNGLE PIGS AND PORCUPINES—THE CACAO CROP—GOLDEN VISIONS—PLENTY OF LAND OFFERING FOR TEA CULTIVATION—THE CEYLON CO. LD. AND O. B. C. ESTATES: A SCRAMBLE FOR THEM AMONG FINANCIAL COMPANIES LIKELY—CEYLON TEAS AND THE POSSIBILITY OF A FALL IN PRICES.

3rd February 1885.

It is not often we hear of young coffee doing well in these days, nor indeed of people bold enough to plant it. It has been generally recognized for some years back that young coffee does not grow as it used to do, turning out bad in every way. It is all the more worthy of record therefore that such a young clearing as Happootella did its 5 cwt. per acre last season at two years old, and a half of that is again expected from the same coffee this year.

Cacao has already so many enemies, that it is far from pleasing to learn that our jungle pig has to be added amongst those. So expert has it become in its endeavours to get at the cacao pods, that it is almost rivalling in intelligence its learned brother at home which at country fairs is the delight and surprize of the simple bumpkins. Intelligence of this kind may be admired but it is not appreciated, and one is almost inclined to indulge in strong language when you come upon the havoc these marauders have made: but when the animal goes the extreme length of undermining the tree whose pods are beyond reach until such time as it topples over, then, I think, it is serious enough to justify a resort to expletives. There is one comfort about the matter, that the jungle pig is easily scared, and as Ramasami has a weakness for his unclean flesh he is always willing and anxious to borrow the estate gun and ammunition, sit up for a night or so, and do his best to entertain the grunter with a few slugs.

But, as an enemy of cacao, the porcupine is worse. It roams all over the place, gnaws the stems of the trees, tears the bark off in strips, breaks down the branches, and destroys the pods. The brute is also so difficult to get at, sneaking out in the darkness and giving few opportunities for a shot, let the shikari be ever so watchful. I get a suggestion just lately well worth a trial when porcupines are troublesome. It was to tie splints of bamboo round the stems of the trees. This is worth a trial anyhow.

The cacao crop is not turning out so well, I learn, as would be liked, but, remembering the drought of last year, perhaps more than there was a right to expect. In Dumbara however not much more than half of last season's returns can be expected in this. On individual trees you see and hear of wonderful bearing. Many a golden vision is built on them, and the happy possessor puzzles himself what to do with his prospective fortune. One such made this nice little calculation. He was standing before a fine specimen of what a cacao tree should be, and, in counting the pods said to himself: "Ten cwt. an acre at the least. I sold my last lot of cacao at R45 per cwt. in Colombo, and have a hundred acres coming into bearing. One hundred acres bearing ten cwt. at R45 per cwt.! Ah! what would I do with all that money?" Ceylon has been so "sair haudeu doon" of late that one can sympathize with the puzzled planter, and his golden visioo. May it be realized.

I remember meeting a man who made a similar kind of calculation regarding Liberian coffee. Seeds were then selling at 50 cents each. He had several acres of Liberian just coming into bearing, and reduced the price to 12 cents each as an absurdly low figure. Out of the maiden crop he showed on paper—well, I forget really what it was, but it was dazzling enough to make him talk of investing the proceeds in consols and retiring to live on the interest thereof!

Land suitable for tea is for offer in every district of the island. It is amusing, if one be on the hunt, what a selection of good, bad and indifferent places are pressed on one as "just the thing you want." Every shuck estate almost, whose name was inglorious in the days of the glory of coffee, and which has sunk below the horizon for the last ten years at any rate, rises "blushing like the morn," as its fortunate possessor insinuatingly points out its wonderful capabilities to produce tea. No man need be in a hurry to buy for want of offers, for the sellers are very much in excess of those who would invest. Still the price of land creeps up, as it is bound to do in the face of the success which tea undoubtedly is

The Assets Company of London is not going to have it all its own way. One large firm at home has its agent here busily employed valuing the C. C. L. and O. B. C. estates, with the view of taking them over. It is more than likely that there will be a scramble among the London financial companies for bargains in estates, which may reasonably be expected to become valuable properties ere many years are passed. But small capitalists may ask:—Is it necessary that these properties should be put up in the lump? It should be a question with those interested if more might not be realized by selling each estate by itself.

As to the fine prices our teas are getting in the London market, a friend at home writes:—"Ceylon tea has for some time enjoyed what is known as 'a fancy price' far above the real market value of the tea, and, if the quality goes down, it won't fall a few pence per lb., but it will be a ruinous fall, and the wise men will be those who use nothing but picked seed, send home only the best tea, and work their estates as against a price of 1s per lb and not run away with averages of 1s 6d and over. You will be doing a good turn if you can impress on any planters what I say about 'fancy prices.' My remarks are quoted from one of the best authorities of the trade here, and, although London cannot grow tea, it has all to do with enabling it to grow in Ceylon and elsewhere."

PEPPERCORN.

NOTES FROM AN "OLD CEYLON COLONIST."

W. S. AND PROTECTION—"TURNING THE CORNER" AND AGRICULTURISTS AT HOME—R. H. T.'S GOOD STORY OF ECONOMY *in excelsis*.

NORTH O' THE TWEED, Jan. 8th.

Tropical Agriculturist just in. It is interesting and very pleasing to hear once more of such a good old fellow-planter as W. S who writes from the "Blue Mountains," and yet one cannot help heaving a sigh for the grand old times of coffee planting—never likely to return in *our* day any more than the *Protection* W. S. vainly and very mistakenly sighs for. It is very gratifying to hear such encouraging accounts of tea. I only hope it will not be ruined by over-sanguine estimates; for, apart altogether from the action of the arch-enemy *Hemileia vastatrix*, the inflation of a dozen years ago would have proved ruinous to thousands by causing the misguided O. B. C. to empty its coffers into the laps of men who were never known to be guilty of a decent day's work.

If you have turned the corner in Ceylon, it is evident enough that agriculturists at home have not yet reached the worst. Yet, who that enjoyed the late glorious summer and witnessed the bountiful crops could have believed that for the Scotch farmer this would prove the most ruinous season on record. Yet such it apparently is. Farms are being given up in every direction: even food may be over-produced. The best loaf bread is now sold at 1d per lb. "We simply cannot pay rent," said an honest farmer to me the other

day," we could barely live supposing I got the land free." I do not think that Ceylon planters with all their trials can quite realize the shifts to which agriculturists in this country are often put.

Dear old R. B. T.! There were few things he could not extract some comfort or humour from, and during his latter days he was fond of repeating a story of how on a Friday morning he went down to the meat-market to see the Buchan farmers arrive. Some had dogs running alongside, but one really careful young farmer whom he had known in Ceylon) invariably had a *hen* tied below his gig! R. B T. could imagine the use of a dog, but this hen fairly puzzled him, and he was fain to ask for an explanation. "A-weel!" said——, "ye see I bring in my ain mare's feed, an, as the maist careful beast will aye skail a little—ye see, the hen picks it up: a dog couldna dee that, ye ken;" adding with charming minuteness: "I tak good care not to bring a *fat hen*; there wad be na use o' that, ye ken." "This is the kind of forethought and attention to little details that seems now necessary in Scotch farming," said poor R. B T., whom I think I see yet through the smoke of his "Dumbara," with his semi-grave face and curious twinkling eye as he gave this illustration of the careful husbandman.

"CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AND ENERGY."

We now give a further instalment of the papers written with reference to young men seeking an investment for capital and a career for themselves, through tea-planting in Ceylon :—

CEYLON AND THE POSITION AND PROSPECTS OF ITS PLANTING ENTERPRIZE.

A great deal has been written about Ceylon and yet much remains to be written. The latest work is "Ceylon in 1884," by John Ferguson, and in that brief but excellent little work the reader may find sufficient information to prevent his making mistakes as to its position in the globe and statistics sufficient to enable him to grasp its general condition as a colony.

In writing the present paper, however, it will not be out of place to remind the reader of the position of the island. It is situated between 5° 55' and 9° 51' N. lat. and 79° 41' and 81° 54' E. long. Its area 15,809,280 acres. Its greatest length is from north to south 266 miles, and greatest width 140 miles from east to west. On reference to the work abovementioned, it is further explained that 2,846,100 acres are cultivated. Lands in private hands equal about 3¾ million, or one-fourth; the remaining three-fourths belong to the Crown.

In 1505 the Portuguese formed settlements on the island, but were dispossessed in the next century by the Dutch. In 1795 the British took possession of the Dutch settlements on the island and annexed them to the Presidency of Madras, but six years after, in 1801, Ceylon was erected into a separate colony.

With this very brief reference to past history, it will be well to turn to the present time with which this review has more to do, as it is my intention to deal with Ceylon as a field for intending colonists, and I do not pretend to furnish food for the scientific mind.

Having pointed out the position of the island, it will be well to make a few remarks on the manner in which it is to be reached. In these days of competition the choice is wonderful in its variety and withal a very pleasant journey it is in the proper season of the year. The journey from Britain takes from 21 to 35 days according to circumstances: if the traveller goes with the letters (the convenience or inconvenience of which method was once graphically described in the *Athenæum*) the farmer; and if by the slowest Canal steamer, or "ditcher," the latter. The most favorable season for leaving England is October—about the middle. By adopting this course no very cold weather is encountered in the northern latitudes, and in journeying south the heat is gradually perceived. The end of October or beginning of November is acknowledged to be the best time for passing the Red Sea—a place having all sorts of imaginary horrors, which Steam the Tyrant has somewhat dispelled. It is true that a leading breeze may make the heat intolerable, but this is a rare occurrence. I have been through this Sea five times, and never felt that there was anything really to be afraid of—and I never once slept on deck. A great deal might be written on the subject of the voyage, but this has been so frequently described that on this occasion the reader will be spared the description of the storm, the fastest time on record and the testimonial to the captain of the vessel.

What an interest there is, though, in these details to the tyro!

On the subject of outfit the same silence may not be so advisable: because it is to the colonist and not the opulent "globe-trotter" that these lines are addressed.

Pray do not think that a list of clothes is going to be given like a washing-book!

All that is required can be very soon described. Two good trunks, two small tin boxes, a large linen bag like a sailor's, a fitted Gladstone bag and a hat-box are the sum-total of the *impedimenta*, and these should contain a good stock of clothes such as would be worn on the hottest day on record in England, flannel of course being the material which predominates. The thousand and-one-suggestions made by one's friends can all be listened to with attention, and like most advice neglected. A large battery of guns is imposing, but a "little Fletcher" will see most men through their sporting career. Many, though very fond of sport, find that it entails too great risks in the way of health and too great expenditure for those whose capital is not available for extraneous purposes. With sportsmen then it is not necessaary to deal, and to them the introduction on landing will not be extended. Are introductions of any use? Certainly if they are given by people well and favorably known and to others of locally equal repute. It is well not to choose *crowned heads* for one's introducers—better to take the lowest seat and rise, than establish at once a reputation for what the Australians call "blowing."

A few good introductions then will be recommended, and with them the whole little European world will soon be open to the new arrival.

What capital is required to start in the island as a planter? This is a question which is always put and one which is very difficult to answer. Lord Denbigh asked the question at a meeting of the Colonial Institute, and the answer may be repeated with advantage and applied at the reader's pleasure. The Chairman said—"I have also been asked that (viz. the amount of capital required for New Zealand) a great number of times. I will answer it by one short anecdote. I myself took out two servants. They landed in New Zealand both with wives and families: and when they landed they only had their clothes on their back and eighteenpence in their pockets—that was the whole of their worldly goods. I also knew another man, who had £150,000 when he landed in the colony. In result the one who landed with eighteenpence has now an estate worth £40 000; while the gentleman who landed with £150.000 died a pauper. Anybody with brains can do well; and, of course, anybody with brains *and* money can do better than in England; but if a man has neither brains nor money, he had better stay in England,

where he will have the work-house to fall back upon."*

Well, the advice which will now be given is this: Bring no capital in your hand, for the inexperienced man with money will be a prey for the unprincipled merchant or planter. Far better will it be for the intending investor to make sure of a supply of money when his experience shall have taught him the right moment to invest and a good opportunity occurs.

Under all circumstances experience should be gained and a good knowledge of the business in which it is intended to embark. It is a dreadful mistake to suppose that anyone can farm, anyone can plant. Look again at the answer Sir Charles Clifford—Chairman of the Colonial Institute meeting—gave Lord Denbigh. Sir Charles Clifford's servants began at the beginning and learnt what they had to do, and in course of time they knew how to apply the knowledge: the result was success. How very different was the care of the capitalist who plunged doubtless *in medias res*. He had no experience to teach him why one estate or farm or run was better than another. He had to trust to agents and bailiffs; he had no experience of seasons: in fine, no technical knowledge; and he failed miserably and his great capital enriched everyone but himself. And if such instances occur in New Zealand of the fickleness of fortune, it is certainly not peculiar to that country. Ceylon, on the contrary, will compete favourably with any colony under British rule for instances of the vicissitudes of fortune-seekers. It has suffered severely at different times from financial panics.

The *Calcutta Review* for March 1857 cites instances. A property costing £10,000 sold for £350, and another of equal cost for £500. Supposing therefore that a man with capital had arrived a short time before such a crisis and invested without experience, what would have that inexperience cost him?

The same man learning and gaining experience would in course of time have made a fortune. At the present time history repeats itself, and there is a terrible reaction after the inflated prosperity of the decade of which 1874 was the summit level.

I have had some years' experience of the colony, and arrived in it at a time when everyone was quite mad with excitement as to their prospects. There was a coffee "boom," and the scene was not one to forget in a hurry. "In all they undertake they feel the anxiety of a gambler, and not the calmness of a labouring man." This was the state of the Ceylon planter in those days, and nothing can be more hostile to successful agriculture. There seemed a prevalent idea that nothing could be done except at railway speed: acres and acres were planted without any regard being paid to soil, climate, or aspect. All was feverish haste and intense anxiety to be rich all at once.

In Caird's *Agriculture*, page 531, the reader may find a note on leases, and it is stated that in the 108th Olympiad 345 B. C., the Ænonians used to lease land for 40 years. The terms of the lease are given. In 1874 a planter in Ceylon would have expected to retire on a fortune made from the lease of a coffee estate for 40 months.

Too much could not be adduced to illustrate the utter folly of rash speculation in tropical agriculture. In the *Spectator* of May the 10th, 1884, there is an able article on the Oriental Bank in which the habits of planters are commented upon:—"When a planter has made money, he goes 'home' to spend it, leaving his successor, be it partner, agent, or assignee, to meet all the requirements for wages, new machinery and cultivation, the best way he can, that is, in fact, by borrowing." Supposing the typical English farmer (the gentleman farmer is not included) were to be off to Paris every time he made a good speculation in sheep or got 10 quarters of Rivett's wheat per acre at 50s per quarter (a fact in 1868), would one ever have heard of a farmer making a fortune? or a farm remaining the same for half a century in point of condition? True it is that change is necessary for the European who settles in the East; but the change is not required to that degree in the island of Ceylon that it may be on the larger portion of the Continent of India, or Hindustan. Hence that mania for going home (or for leaving home to speak more correctly) should not exist if the Planter who wishes to prove "that the land be werry honest, whatever you do put into it, you shall get back again." Many, if the truth were known, could date their misfortunes from the evil day when love of their country—sudden and spasmodic!—induced them to break up and scatter their Lares and Penates and visit their friends in the old country who perhaps would have preferred their room to their company!

What is the best investment in Ceylon at the present time?

Tea undoubtedly, but it is a product which has only ately come into notice. In 1867 there were 10 acres in the island, and in 1877 the acreage had risen to 2,720. In 1883 there were 32,000! And now there is a rush and tea is being planted everywhere. It is a wonderful success in many places, and it can be extended still farther. Land can be obtained at the upset price of R10 per acre. Survey and other fees added in some cases as much as 30 per cent. Old coffee estates—abandoned wholly or partly—can be bought very cheaply and planted up. The yield of some of the best bearing estates is very large—as much as 1 000 lb. of prepared tea per acre. Elevation seems to make but little difference, for estates at sea-level and estates at 6,000 feet above it have made equally high prices for prepared tea. The labour question at present gives no anxiety, and tea estates are sought after on account of the regularity of the work. There is an abundance of seed of fair jât in the island which can be obtained at moderate prices.

There has not yet been any speculation in tea estates, but the time may come, and the happy possessor of an estate may find a good sale. The whole of the Central Province or mountain zone is suitable in climate for tea and the insular climate is a great advantage. Again at a time when the fruit-grower is crying out at the cessation of his trees from bearing, a product is introduced which is cultivated for the leaf only. Post-fact wiseacres have remarked that tea was the proper product for Ceylon and not coffee. The best known estate, it must be borne in mind, has peculiar advantages It is close to a railway station, close to a town, and has a cart-road (Government) right through it Compare these advantages with the disadvantages of an estate in a more remote part of the island—say the Badulla district—where there is no railway, labour not too plentiful, and 125 miles of road to be traversed to Colombo.

Nevertheless, if a yield of 800 to 1,000 lb. per acre can be obtained saleable at 1s sterling per lb., a fair profit can be looked for even under considerable disadvantages.

The planting of a tea estate can be done by a coffee planter of experience, and the art of tea manufacturing is now well understood by many, and has been brought in some instances to approximate perfection. If therefore the intending investor were very anxious to commence operations at once, he could live on an estate whilst the planting operations were going on and learn this work, and afterwards whilst the tea

* The rule applies more strongly in Ceylon than in New Zealand, where, as the case of Sir Charles Clifford's servants shows, men having only labour as their capital can get on. But in Ceylon, as in all tropical countries, the openings for the profitable employment of European labour are few and far between.—ED.

was growing, go and learn the art of preparation for the London market. In this way the first three years of proprietorship could be profitably spent and the realization of profits rendered all the sweeter by an intimate acquaintance with the cause and effect.

It is highly improbable that any tables of estimates would be understood by the tyro, and therefore figures which prove anything will be avoided; but briefly to give some idea of how capital would be expended is only reasonably to be expected.

First then let us take the case of an old coffee estate. An estate of 640 acres or a square mile of land is purchased, say for R20,000, or, to make it clearer, £1,666. On this there would be a bungalow, a good store with water-wheel and machinery, and ample accommodation for the coolly labour. There then might be 300 acres of coffee, good, bad and indifferent; 20 acres of cinchona, some good forest and some chena or second growth of jungle or land once opened. The annual expenditure on such a place would be, say, £1,200 and crop value of coffee and cinchona £1,440. The coffee crop being 400 cwt and the cinchona about 2 tons, a profit of £240 would be left with which to plant tea, and the cost would be about R50 to R60 per acre. (The rupee is estimated at 1s 8d.) The weeding and all expenditure on roads and drains for upkeep would be found in the estimated cost of maintaining the developing coffee estate: hence the capital required for such an undertaking would be £2,000 to £3,000, and the proprietor should be perfectly free under such conditions from all agents and mortgagees.

Having finished with the last favorite, I will now proceed to touch upon the last but one, viz., Cinchona. This product was in great favour a short time ago, until it was discovered that it did *not* flourish, like Horniman's tea, always good alike. On reference to Ferguson's Directory it will be seen that the product was known a long time ago, but during the halcyon days of coffee little attention was paid to it. A well-known instance is quoted of the fabulous prices realized by sales of bark in the early days—that is to say, up to 1880. Ten shillings and two-pence per lb. was obtained for cinchona officinalis quill bark. But space will not admit of going in for all these details and statistics: they may all be found in that marvel of compilation, the said Ferguson's Directory. The subject now before us is the present position of the enterprize. To deal with this, we must leave alone isolated instances of great profits and take the market value of the unit of sulphate of quinine on which to base our calculations.

Before, however, looking at the financial success of the product it should be viewed agriculturally.

I quote a sale of a cinchona estate which has just taken place to show how bargains can be picked up. The estate was the Tullibody estate near Nuwara Eliya and the price paid was R13,000 or £1,000 sterling at present rates of exchange. The estate was thus described in the local papers:—"248 acres more or less—65 000 trees from 9 months to 7 years old. Buildings consisted of a bungalow, stores and cooly habitations. The estate was well drained and 'admirably suited for the cultivation of tea.'"

Circumstances alter cases; but there must be some very peculiar circumstances about this estate if it be not a case of a bargain. For my own part, I would rather have a plantation at Awisawella or Kalutara, two lowcountry places, than live at the high elevation of Nuwara Eliya, where one encounters the one thing to avoid in a tropical country, namely, cold! My first experience of the place was in Christmas 1875, when I ascended Pidurutalagala, the highest point in Ceylon, and felt such a chill as I shall not forget. My companion, an old gentleman, got congestion of the liver from it. There were frost and ice on the puddles in the road, *jam satis terris*, &c. I came to avoid cold, and here I was in the zenith of the Christmas Father's glory. I do not recommend Nuwara Eliya and its neighbourhood.

Of course, it must be thoroughly understood that the typical estate is one that has been forced into the market in times of great depression, for it might be truthfully said that a practical planter who so sacrificed a good concern would be a fool. The picture is not altogether overdrawn.

Where can cinchona be grown? For my part, I am prejudiced in favour of a certain district; but I do not fear contradiction when I say that it cannot be grown in clay. When the product was looked upon as a means of evading ruin it was the fashion, wherever a bare ridge or patch of vacancies was seen in the coffee and elicited criticism, to say: "Oh! plant it up with cinchona" (and to realize the full weight of this you must pronounce the word with a Scotch accent). Time proved however that this was as great a mistake as the indiscriminate selection of land for coffee. When there were a few planters and a few coffee estates, men of experience used to select good land, but when the rush came, people sought the flimsiest excuses for making out that land was suitable. A well-known visiting agent,—an itinerant land agent—used to say to me when I first came to the country, 'good soil' or 'good climate' of nearly every estate that I asked him about. Now as it is notorious that the soil of Ceylon is not generally good, this was peculiar to say the least, and did not argue in favour of the gentleman's good sense.

Cinchona requires a soil with a good mixture of stone and sand or quartz. Heavy moist soil does not suit, nor slab rock; and a field that I know has apparently nothing but quartz, but here the plant seems quite in its element.

And as to climate. A dry climate is the best, and this is found on the eastern side of the mountain zone. The critical time, viz, the age of three years, can here be passed safely, and one may look for trees of a great age comparatively speaking. The present fashion is to spokeshave the bark off the trees and after the first operation, wait 9 to 12 months and repeat it. The first is the original bark and the second the renewed, of commerce. I will give an instance of what the cinchona succirubra will do. Original shavings off 5½ acres weighed 1,500 lb. and analyzed 1·65 sulphate of quinine, the renewed off the same acreage weighed 2,000 lb. and analyzed 3·31 sulphate of quinine. The trees are still standing and the bark has renewed very well the *third* time. In the first instance the bark would be worth 8d per lb and the second 1s 4d, so that the gross proceeds (with unit at 25 cents currency or 5d) would have been 1st year £50, and second year £130—the actual results were much better than this. The cost of harvesting may be put at 2d per lb. I should not recommend shaving any tree under three years old, and indeed it would require that soil and climate were all in favor of the plant's growth to shave at so early an age. At four years old the operation may be considered safe, and the tree sometimes seems to thicken and grow after it. Great care is necessary however not to injure the 'cambium.'

Most people know how to destroy trees by 'ringing' the bark, and if the actual wood is exposed the operations of shaving and ringing are synonymous. After the second shaving it will be well to coppice, and in so doing cut off the trees leaving a good slope on the stump—suckers soon spring up, and two or three will grow to a great size from the one stump. I have suckers growing in this manner that

are equal in size and strength to a stem of the same age from an original plant.

A cinchona estate arrived at the age of three years old from jungle would be rather costly, because buildings would be required, with the exception of store, to the same extent as a small coffee estate. A bark store would be necessary.

Roughly speaking I would not recommend a smaller capital than £2,000 for an estate of 100 to 150 acres. Of course, as in entry on a farm, the whole amount is not immediately necessary; but whereas the harvest would come in a year, say, on a Michaelmas entry; in the cinchona estate it would be delayed for three. In the first year all the planting operations would be done, the buildings put up at least for the labourers, and subsequently, weeding and improvements and supplying losses of plants by death and insect enemies. Handbooks on the cultivation are written, and in these all the details will be found. It is just possible that the proprietor might arrange to live with a neighbour if there was one near the jungle and so the erection of a bungalow could be delayed until he saw that his "agricultural venture was a financial success."

But some one will say: "How long is this cinchona plantation going to last that you talk of buildings and bungalows?" I reply that if it be a success it will last quite long enough for its owner to spend his capital and get a very fair return for it: after that perhaps he may wish to enter upon some other speculation. Three years before harvest and three years of harvesting are ample time for a man to decide whether he will remain in his voluntary exile, and ample time for him to "spoil a horn or make a spoon." I do not think a cinchona plantation would last for ever, nor any cultivation in the tropics that meets the approval of the European. If he means to spend his life in a climate admittedly unsuitable to the European constitution—and in many cases made so fatal by utter want of commonsense in personal habits—he should plant coconuts, nutmegs, or buy paddy (rice) fields, and live as abstemiously as a high-caste Hindu. Cinnamon, too, is a good lasting investment, and has enriched more people than any spice the white man has grown. There are so many drawbacks to all these products that it is scarcely necessary to mention them except in the way I have done. The European planter as a rule has in his mind's eye large profits and quick returns and will not wait for a slow but sure concern.

But to return to Cinchona. In it as in tea there is no fruit, no blossoming season, which have of late years given the poor coffee planters so much anxiety, but in contraposition the uncertainty of the market value may be placed. If it be true that present prices only remain as they are on account of the large sum lent on the stocks of bark, then I fear that there is a bad time coming for the cinchona planter, but if increased consumption (owing to the price of the manufactured article being low enough to place it within reach of the million) continue, then 5d per unit will make the planter a profit, and every 1d above that will lighten his anxiety and increase the weight of his purse. Prices are now rising. I feel that to enter deeper in detail and mention the varieties of cinchona,—all household words to the experienced planter,—is here out of place, so I dismiss the subject of cinchona and will proceed to coffee.

At the commencement of this subject I fancy I see the pessimist who

> "beheld their plight
> And to his mates thus in derision called"

at the bare idea of a man writing about coffee in these days! Laugh and deride, Mr. Pessimist, Mr Merchant, or whoever you may be; but perhaps you have not much to laugh at. You had not the money to invest in the year 1874, before alluded to, and now take credit for perspicience. Or, you recklessly risked your own and other people's money in 1874, and now regard yourself as a special subject for compassion—one who has received no Providence. Yes, I know well the ways of the 'turn-coats'! "Ruined, eh?" "Yes; but, has coffee ruined you"? "No, but leaf-disease (*Hemileia vastatrix*) has." "Has leaf-disease killed your coffee?" "No, but it has spoilt the crops, and there was no money for cultivation, so it *snuffed out*." "What became of all your large profits when coffee paid well say from 1869 to 1876? Was there no leaf-disease then?" "I thought the large profits were going on for ever: indeed some said coffee would go up to 200s per cwt., so I spent them. Yes, there was leaf-disease, but manure and cultivation seemed to keep it from being very bad." "And could you not get any credit for working your estate, if not expensively in such a manner that you would be ready for a good season if it came?" "Well, no, I was pretty heavily mortgaged, and my agents would not allow a cent beyond what paid from the mortgagee's point of view." "So your coffee after being highly cultivated and stimulated was starved, eh?" "Yes, I suppose it was?" "And have none cultivated their coffee since these hard times came?" "Oh, yes, a few I believe." "And in what condition are these estates—'snuffed out'?" "No, I believe the other day there was a case of an estate cultivated well, being much admired by the mortgagee or an agent, and he said that he should not think of turning out the mortgagor." "Then it is possible to cultivate coffee to a profit even with short crops and low prices." "Well, I am out of it, so I cannot give you my experience; but I suppose if it were not —— and —— and —— & Co. would have shut up shop long ago. They are all heavily mortgaged, and if they did not pay would be sold up; so there must be the interest that they have to pay above and beyond working expenses allowed." "What about a proprietor who is free of all mortgages, cannot he make a good coffee estate pay, for I suppose a bad coffee estate would be just as great a loss as a bad farm or a bad horse?" "Yes, I suppose he might show a profit over working expenses, but he would not be able to show anything like a fair interest for his money, if he bought in 1874 at the then market rate." "Exactly, but in the latter emergency he is not different from many capitalists who invested in land in England about 1870. Land was then bought to pay about the same interest as consols at 92½, and rents have now fallen so low that perhaps it only pays about 1 per cent or so."

I will not prolong the conversation, but I do not hesitate to say that a great deal of the depression now being experienced is owing to human folly and not divine intervention. My own feeling was when I first came to the island that perhaps if I were fortunate I would obtain double the interest for money that I should get in the old country, but of course there was more than double the risk. At first I was very cautious, and would not accept the off-hand representations of huge profits which were given to me. But at last I doubted my own judgment and listened to crafty people and "plunged," with the result that I have learned a very bitter lesson. I did not do as I have advised. I invested before I had gained experience, and others made money while I lost the capital which I introduced. Like many others I had something good and something bad, and the bad was always dragging me down. At last I cut the Gordian knot and let it drift at a ruinous sacrifice, and now am free to speak of only the good. I believe that besides a living I can make a

small profit over working expenses, though of course I cannot get even a fair interest for the capital invested. Crops, too, have steadily gone down and now seem to have found a level at about two to three hundred, weight per acre which at present prices leaves little margin of profit. That this average of crop could be raised by judicious cultivation I do not doubt, having very good authority for the assumption; but there are historical reasons for the cultivation being denied to the suffering plant, and therefore things remain *in statu quo*. I do not suppose that you would find a single person so bold as to say that they would still depend on coffee planting to make them a living. Perhaps they may be right if they are thinking of the old districts known as the Kandy side; but in Uva or the eastern portion of the Central Province beyond Nuwara Eliya and looking towards Batticaloa and Hambantota the case is different. Here soil and climate have rendered the struggle of the coffee against adverse seasons and disease and neglect prolonged, and should succour come now in the shape of Government recognition of the requisitions of the coffee planter, I believe that these districts might still flourish and be profitable in this product alone to their proprietors. Having had experience in agriculture I know that it is not every one that can farm successfully, and pitchforking money into the land does not constitute good farming. There was a time (in the early days) doubtless when a man could hardly fail to succeed in coffee planting because the demand for plantations was not great and there was plenty of land to select from. The best land got taken up and then when a rush came, people went in for the second best and so on until there ceased to be any good, better, or best left, and land was opened, which the old pioneers would have shunned like the plague. Besides this a vast area was opened and a late Governor remarked that in no country in which he had been, had he ever seen such general devastation of forest as in some of the new coffee districts of Ceylon. Is it a matter of surprize then that a number of years of great fertility should be succeeded comparatively by a few years of sterility? The farmer in North America has a large quantity of land to select from, and he sows his seed in virgin soil; when he has got a crop from one piece of land he goes on to another, the soil is there and no exhaustion has yet taken place. In like manner in Ceylon. From what I have heard even this deep virgin soil in America will not crop year after year without cultivation or rotation of crop; and in Ceylon the one crop was perpetual and no change was made. And the same land was always cropped, coffee being never replanted as in some countries, Java for instance.

A blight came on the coffee in 1869, followed by the unprecedented prices in 1870-80. Whilst these high prices continued manure was put into the land without stint and without method. Everything was done to force the crop. When the coffee plant became keenly susceptible of stimulants, they suddenly ceased on account of a fall in prices and a withdrawal of the confidence of the capitalists.

The coffee seems to be less to blame than its treatment.

A farmer never knows his business, and the seasons he admits beat him. The coffee planter expects to learn his business in a few short years, and rarely studies the seasons. The cultivation went on in the old jog-trot style, and it was only with a rise of prices that innovations came, and with these entirely inexperienced men.

Coffee then is under a cloud, and it will be almost useless to waste more time in describing the land suitable for it, because there is none left. It will be useless to describe the manner or cost of planting, because no one would have faith enough to plant it if he had suitable land it will be useless to describe or estimate the profits, because the crops do not come. But——and there is always a "but" in every case——I should advise any possessor of good coffee to stick to it and do all his purse will allow to preserve it against a possible return of favourable seasons and the departure of leaf-disease. In conclusion, I am told that there are many worse places than Ceylon, by one who has been round the globe, and I can quite believe it. I have a great friend, with whom I lived in Ceylon; he is now in the Far West. He described to me that his prospects were to become a fairly good agricultural labourer. He had, after some months' residence, a few acres of grain, potatoes and onions. He and his brother were then quite alone, and after his experience of an abundance of native servants and cooly labourers this must have been very trying. Yes, I should be inclined to say that for a gentleman who has from £2,000 to £5,000 capital to invest he might do worse than come to Ceylon. "*Spectatum veniunt, veniunt spectentur ut ipsi*," will be a good rule however, and if the inspection is unsatisfactory do not go further. If it be very satisfactory do not fail to make it long enough to verify first impressions. There are few hardships in the country. Provided that you have plenty of Tamil or Sinhalese labourers for transport and a little money, there is scarcely any necessary you need be long in want of. Colombo is one of the finest towns in the East. Kandy, besides being well supplied in every way with comforts for Europeans, is one of the prettiest. Badulla is a very good specimen of an outstation; and besides these there are Matale, Gampola and Nawalapitiya that may rank as quite civilized places. Nuwara Eliya, the hill sanatorium, and on the Badulla side Haldummulla, Passara and Lunugala, all with post offices and regular daily mails. Telegraph offices at all the principal towns, good English and native shops, mails every week from England, steamers going and coming almost daily to and from east and west,—all this makes life worth living.

There is plenty of good food to be had;- it is the fashion to run down the beef sometimes, but you cannot expect "Welsh-runts*" in Taprobane,—and very cheap it is! A single man can live very comfortably on £200 per annum and need not owe a single bill. Horses are fairly cheap and horsekeep is not more than £3 per month. Of course all imported articles are dear and just about 100 per cent over cost price in England, *i.e.*, what costs 1s in England costs R1 here; but allowing for exchange this would not be cent per cent. Nevertheless, the calculation is near enough without splitting straws.

As for health, in the hills the matter lies almost entirely within the power of the resident; and in these days of moderate drinking and almost complete absence of beer one may enjoy as good health as in one's native village in England. Plenty of exercise, plenty of flannel ("white things" I abhor!), care about the sun and sobriety are the main points.

To all who read these remarks I would say: "Come and see the place, and if you do not like it there will be no harm done, only a few pounds gone in a pleasant voyage! I for one will give you a welcome and any information that lies in my power."

Dec. 31st, 1884. A. C. I.

INDIAN TEA COMPANIES.

The following notices have been issued:—

BORELLI TEA COMPANY, LIMITED.—The season has closed with a crop of 377,034 lb., being a decrease of 18,966 lb, from last year—due to the exceptionally dry weather ex-

* Some of the finest beef extant.

perienced throughout the manufacturing season; this being the second year of short rainfall. The sales to date have comprized 182,405 lb. of tea, which have realized a gross average price of 1s 2⅞d per lb. (against 177,915 lb. sold to this date last year at an averge of 1s 3¼d), which, considering the recent fall in value of Indian teas, may be considered fairly satisfactory. In view of the unprecedently low market, the directors have not felt justified in paying more than 2½ per cent as an *ad interim* divividend.

MUNOLEDYE TEA COMPANY, LIMITED.—The season has closed with a crop of 277,399 lb. of tea, against 434,059 lb. last year—a difference of 156,660 lb. This large decrease is partly due to the remedial treatment for strengthening the plants, deemed necessary by Mr. Beyle, of which lighter plucking for one season was an important detail; and also to the protracted and severe drought which has prevailed throughout the season. The quantity sold to date has been 121,894 lb., at an average price of 1s 3d per lb., against an average for sales to same period last year, of 1s 0¾d per lb.—showing considerable improvement in quality. The superintendent is confident that the measures he is carrying out for the improvement of the property will prove successful, and be followed by increased outturn as well as a higher class of produce. He is also introducing changes in the mode of working, which will tend to lessen the cost of production; and though the outcome of the past season cannot fail to be disappointing to all concerned, the directors share the superintendent's hopeful anticipations as to the future.—*H. & C. Mail.*

SEASON REPORTS FROM SOUTHERN INDIA.

Read the following telegram from Collector of Tanjore, to Secretary to Government, Revenue Department, dated 5th January 1885:—Rice 11·54; cholum 20·69; ragi 22·22; cumbu 21·51. Rainfall: Shiyali 0·25; Tiruturaipundi 0·10; no rain in twelve stations; report not received from two stations. For week ending 27th December 1884.—Vedaraniem 1·50. Rivers two to five feet. Crops good, except in parts damaged by the late floods and rain. Harvest: paddy, ragi, outturn below average. 571 deaths from cholera; in other respects, health of people and cattle generally good.

The following report from Collector of Trichinopoly, to Secretary to Government, Revenue Department, dated 5th January 1885:—Rice (second sort) 11·76; cholum 19·60; ragi 21·96; cumbu 19·85. Health: Cholera increasing and smallpox slight. Cholera attacked 425, died 267. Crops good, except in parts damaged from the recent rains and flood. Agricultural operations—Sowing, transplanting and weeding continue in parts; paddy, cholum, cumbu and samai were harvested in Musiri and Kulitalai taluks, with outturn between 8 and 12 annas. Water-supply—The Cauvery is gradually falling; the river-channels in general have a fair supply; there is a sufficiency in rainfed tanks in dry parts for both irrigation and drinking purposes. Rainfall *nil* throughout district and Pudukota.

The following telegram from Collector of Madura, to Secretary to Government, Revenue Department, dated 5th January 1885:—Rice 11·14, cholum 19·17, ragi 23·25, cumbu 21·1. No rain: number of stations where there is no rain, or from which no reports have been received. 9. Previous week—Tirushuli 0·25, Usilampatti 0·8, Tirupatur 0·25, Morekulam 1·87, Vattanam 0·85, Ramnad 0·55, and no rain at the remaining five stations. Health of cattle good, and of people not satisfactory; cholera throughout; fever prevalent (total deaths 316). Water-supply sufficient. Pasture fair. Prospects doubtful. Flood in Vaigai subsiding.

The following telegram from Collector of Tinnevelly, to Secretary to Government, Revenue Department, dated 5th January 1885:—Rice 11·28, cholum 18·2, cumbu 19·68, ragi 24·66. No rain during the week. Height in Tambrapaani reduced to 2 feet. Cholera in all taluks, severest Sirvilliputur (attacks 420 and deaths 340); all other taluks attacks 1,414 and deaths 1,125; efforts to check it continued; cattle-disease slightly prevalent in nothern taluks. Tanks generally full. Cultivation proceeding almost everywhere. Crops in many places blighted by late heavy rains. Harvest of dry crops going on Sankaranainarkoil, Sirvilliputur, Satur, Tenkarai, outturn average in Sankaranainarkoil below average in others; wet harvest Tenkarai, outturn average

The following telegram from Dewan of Travancore, to Secretary to Government, Revenue Department, dated 5th January 1885:—Season telegram, Trivandrum—Paddy ripening. Price—Madras second-sort rice 9·6 and paddy 23·9 seers per rupee. Three deaths smallpox, Trivandrum; smallpox, cholera still prevalent in several parts; fever lingering. No rain.

INDIAN TEA IN AUSTRALIA.

Redmyre, Sydney, N. S. W., 29th Dec. 1884.

I lectured on Indo-Australian Trade with a special lecture on tea in the great hall of the Technical College here, the course comprising six lectures, prepared with considerable pains, and the audiences overflowed the seats, and both the public and the press testified in the most emphatic and complimentary manner their interest in my subject, and their appreciation of the discreet and impartial way in which I handled it.

It is well-known here, albeit Mr. O'Conor may dispute the fact, that the services of Mr. Moody, myself and other friends of Indian tea have had at least this effect, if no other: the importation of low class Chinese rubbish has been checked. Those interested in Chinese teas saw quick enough that the Indian tea only wanted "free course" to sweep all before it, if better quality was not sent down from China. And since the Sydney and Melbourne Exhibitions, it is notorious that better grade teas have been sent from China than was formerly the case. So much may the Australian tea drinker be grateful to India for.

The "tact and discretion" of the colonial tea dealer may find illustration in such a case as this, by no means an unfrequent one. A very old firm, high in position, formerly one of the largest importers of Chinese low class rubbish, sold to a young firm in this city some two or three thousand pounds worth of cheap Chinese tea: the tea was sold by sample, and the sample was a perfectly sound flaky broken tea, and suitable for certain requirements. Deliveries at first were up to sample; then another totally different shop mark, an older and inferior tea, BUT HAVING THE SAME SORT OF MATS OUTSIDE, THE SAME OUTSIDE LABELS AND MARKS, began to be mixed up with the tea as originally sampled and purchased. When complaints began to come in from customers, suspicion was aroused. The fresh untarnished mats and labels on an old tea was alone sufficient, and a searching enquiry was instituted. A survey was held, experts were called in, and it was proved, beyond a doubt, that a much inferior tea to that sampled, a tea rotten, and damaged, and unmarketable, saturated in some cases with oil, stained with salt-water, had been palmed off as good tea on the unfortunate purchaser. The old mats had been taken off, and NEW MATS and FRESH LABELS, presumably kept in reserve for this nefarious purpose, had been substituted. This rotten muck had been in stock for some years, but had been forced out of consumption by the superior standard set up by the introduction of pure Indian tea.

Another man writes from upcountry to a firm in town: "I have taken a large contract to supply tea to the blacks. What is the cheapest stuff you can sell. ANYTHING WILL DO, SO LONG AS IT IS LIKE TEA." That speaks for itself. Would Mr. O'Conor like to taste some of the so-called tea served out to shearers, to bushmen; in the forecastles of coasters by potty contractors, &c.? Are all the descriptions of "lie tea," of "maloo mixture," of green deleterious teas, of adulterated and twice used leaves, "packed up" by Chinamen? Are all these fables, myths, inventions of the enemy, myself and Mr. Moody?

My own opinion, to which in my lectures I have always given expression, is, that, for many years yet, Indian tea will be chiefly used as a blending medium, to fortify weak China teas; and that under any circumstances, at present at least, the best drinking tea is a blend of pure Indian and GOOD China. The use of Indian teas is becoming now almost universal in blends, and I am quite certain that a big market will yet be found in Australia for the subject of my lectures, and Mr. Moody's straightforward, painstaking and instructive analyses.

As I am on this subject you may pardon me if I just occupy your space a few inches more. In May of last year I received from the Under-Secretary to the Government of India, in the Department of Revenue and

Agriculture, a communication, asking if I could explain the causes of the rapid decline in the demand for Indian tea in Australia.

I do not think it is any breach of confidence if I give you the substance of my reply.

I said, to give an adequate answer would take up more time than I had at my disposal, but I might briefly state my opinion on a few of what I considered the causes.

Item.—It was I think wrong policy to appoint only one agency at the first. In many of my letters to those interested in Calcutta, I pointed out that a sudden change from China to Indian tea on the part of consumers was scarcely to be expected, and I suggested a multiplication of agencies, a widespread publicity, and the distribution of the tea in packets, &c. This policy was not followed. One central agency was established, and the sales were forced at public auction, and the teas sold at much below their value. This raised a false issue. Price, and not quality, became the desideratum, and, as a matter of fact, the greater proportion of the large supplies of Indian teas sent down were bought up by large tea-packing companies, because they got it cheap, and much of it is still in their hands and is being used in their packet business. Now that they can get no more Indian tea at the cheap rates they at first bought at, they are quite content to revert to the cheaper China teas.

Another cause is, that, during the last two seasons, there has been a more than usually abundant supply of good medium qualities of China teas. The good values offering in this grade in China tempted consignors to substitute these for their orders for common teas. The result is, that, for the last twelve months, medium Chinas have been over-abundant and cheap, while low and common have been scarce and dear. The improvement in the quality, too, may be partly due to the introduction of the Indian article.

The real point however I opine is, that grocers here are averse to taking trouble. They will NOT mix and blend teas, as the English grocer does, so long as they can do as well with unmixed teas. The trade in Indian teas in England was worked up slowly by *persistent, continuous* effort. It was a work of time, and so must it be here.

The experience of the firm of which I am a partner is, that "our sales of Indian teas have increased during the past year." JAS. INGLIS.

[Mr. Inglis is well-known as author of interesting works under the name of "Maori." Mr. Buck put the Indian Court at Melbourne under his charge.—ED.]

TEA GROWING IN CEYLON.

(From a Correspondent to the Calcutta "Englishman," Jan. 21st.)

The extension of tea cultivation in Ceylon has of late been extremely rapid. In 1873 between 200 and 250 acres only were under tea, and up to 1878 this area was but little increased, but in 1883 there were 35,000 acres under plant, though of course not all yielding a return. Coffee reached its lowest point of depression in 1879, and its recovery has now been despaired of by the most sanguine. Of course there have been, and will be, fluctuations in the market, but its production is steadily on the decrease, and will probably continue so until either it ceases to be one of the staple products of the island, or shrinks to dimensions too insignificant to be taken into account when estimating the productive resources of the colony. In 1863 one million cwt. of coffee was exported from Ceylon, and last year the export was only 333,000 cwt. Tea on the other hand has expanded from 23 lb. in 1876 to 1,522,882 lb. in 1884. Of the 48,000 acres under tea cultivation in 1884, almost all are at comparatively low altitudes, but recent experiments tend to prove that in Ceylon tea may be profitably grown at an elevation of from 5,600 feet, as at Nuwara Eliya, to 6,000 or 6,500 feet, in which case the area of possible tea cultivation may be roughly estimated at from 150,000 to 160,000 acres calculated to produce 70 million pounds of high priced tea. I say "high priced tea" advisedly, because all the Ceylon tea that has been sent home up to the present has realized prices which would, if obtained as generally for Indian teas, cause a change in the aspect of Indian tea cultivation as an industry which is most devoutly to be wished. There is a subtle aromatic flavour about Ceylon tea which an Indian tea lacks, and it is, though peculiar, one that seems to recommend it to the most uneducated palate. Though on the other hand I incline to the belief that so distinctive a characteristic is calculated to cause its popularity to be somewhat ephemeral unless bulked with some other tea calculated to render this peculiarity somewhat less prominent. There are many other advantages possessed by the Ceylon planters over their less happily situated Indian brethren. Incredible as it may seem to us here in India, the Government so far from being hostile to them and interposing difficulties in the way of their getting labour, and checking their "spirit of ascendency," is actually affording them practical assistance in their undertaking, though this evidently proceeds from the notion (shared in by every Government but our own) that in turning barren land into productive gardens, affording work and the means of support to a large body of men, and introducing a new industry while doubling the productive resources of the island, these men, in serving themselves are also affording very material service to the State. Of course the idea is a falacious one, but, somehow or other, under these favourable auspices tea is making grand strides. Wherever one goes one sees clearances and new extensions, roads being made, bridges built, slopes terraced, and signs of general progress on every side. It is impossible to predict what the future has in store for India, but if ever it is realized in this country that the folly of today is the wisdom of tomorrow, we may learn, before the bulk of our tea trade is gone, that perhaps the Ceylon Government, in the cordial assistance they are giving to the planters there, are not so very foolish after all, and that, beyond crippling to a considerable extent a very promising addition to their exports, the Government of India has not achieved a brilliant success.

The planters in Ceylon possess four other advantages, second only in importance to that just specified. These may be briefly stated as labour, freight, carriage, and tenure. As to the first, it is cheap, and—judged by our Indian standard—by no means bad. The coolies are Tamils imported from Southern India—and in the way of this—*mirabile dictu*—the Government of Ceylon interposes no useless obstacles, but on the other hand, positively indicates a disposition to assist both coolies and planters. The coolies themselves, like those in this country, are of a contemplative turn of mind, and would apparently prefer to pass their time equally between eating, sleeping, and silent meditation, but a mature consideration of the probable result on pay day of such a course suffices to convert them for a certain time into *quasi* industrious people. They are, moreover, quiet and orderly in the extreme, and no inducements are held out to them to be otherwise. As to freight, the Ceylon planters ship from Colombo for two annas per lb. less than the Indian planter can ship from Calcutta, and, when we add to this, good roads, a railway close by, clearance wood, a marketable commodity, and the best virgin soil procurable at £1 per acre on a title known as Crown Freehold Title (with easy conditions as to clearance) and that title guaranteed by a friendly disposed Government, no risk of being shot by some border tribesmen, no chance of being "raided" out of house and home, a good climate, rain on an average every week, and not fifty-two weeks' rainfall concentrated into five, no floods, no drought, no red spider, and within a day's run of the seaside, the Ceylon tea planter may well exclaim: "Truly the lots have fallen upon me in pleasant places."

So far the picture is indeed a bright one, but just, as has been wisely remarked by some one, "Life is not all beer and skittles," so there are drawbacks, and it may be serious drawbacks, to so bright a prospect. Ceylon, in the hill tracts at any rate, is nothing if not rocky, and in the vast majority of places the soil that covers the rock is of no great depth, and is diminishing every year. So long as the forests remain uncut, they protect the hill sides from the direct impact of the rain drops, diffuse the water more generally over the ground, and interpose a shield in the shape of fallen leaves, which, by an increase in the area of exposure, also assist in keeping off such water as may reach so far. But when this shelter is removed, and the steep hill sides, with their friable soil, are exposed to the rain with no other protection than that afforded by a more or less developed tea bush, the "wash" becomes a very serious consideration, and it is a common thing, in a place which has

been any time cleared, to see the rock showing through in different places, and the unmistakable indications of a slip in its immediate vicinity. All the terracing in the world would never remedy this evil under such conditions, though it might modify it, and, of course, the effect of manuring would simply be nil, so far as the plants were concerned, on a shallow soil like this. When the tap roots get down to a rock, which elsewhere has a large exposed area not far from the bush, the effects of the heat inevitably carried to that portion of the rock in contact with the roots, may prove more than theoretical. Terracing also means constantly recurring labour. To thoroughly appreciate the condition of things, it is necessary to see some of the hill gardens in Ceylon, and to note the terrible scour along some of the terraces which are of a sufficiently gentle gradient to secure one from serious loss in any but a soil like that in question. This, and the impossibility of profitably manuring a hill garden when once impoverished, and the fact that the majority of the tea gardens in Ceylon fall under this category, are the only unpleasant features in this otherwise happy picture. If any tea planter in India wants to employ his time pleasantly and profitably too, he cannot do better than go to Ceylon and see some of the new gardens that are now springing up on every side.

PLANTING IN WYNAAD:

THE NEW LAND SETTLEMENT—MAISTRIES' ADVANCES—MINING IN WANAAD.

There has been some further correspondence between the Settlement Officer, Mr. Stuart, and the Honorary Secretary of our Association, from which it appears that a radical change in the method of taxing land in Wynaad is not only in contemplation, but has already been decided upon. This change consists in the "substitution of a charge upon occupation for a charge upon cultivation only as at present;" the object being to do away with the necessity for yearly inspections, and a certain not very large sum will thus be saved to the revenue. It is just conceivable that in a much more flourishing period than planters are living in, this change might do them no harm; as things are, it will inevitably lead to the hasty abandonment of a large portion of the land at present in cultivation, and to a permanent reduction of the acreage under coffee. An invitation has been issued by the Association to all landholders, whether members or not, to attend the meeting on the 7th proximo, when, as I mentioned before, the Settlement Officer is to be present. It is well that our Honorary Secretary and other leading planters should have an opportunity of stating their views on the various changes that are to be made after the completion of Mr. Stuart's work. These gentlemen may be trusted to do all that is possible to protect the interests of our community, and as the matter is a difficult one to make interesting to the general public, though so important to us, I will only briefly point out how the intended alteration will work. At present our coffee and cinchona land is taxed at the rate of R2 per acre, and in the case of land bought from Nayars, nothing is paid for grass land, or jungle. When any acreage is abandoned, that amount is relieved from taxation. It is now proposed to fix the amount payable for 30 years, at the rate of R2 an acre yearly on all coffee, or cinchona, in cultivation at the time of the settlement, and 2 annas for all other cultivable land. Thus, supposing a planter to hold 1,000 acres, for which he has already paid a large sum to a Nayar, and to have opened 800 acres in coffee, the rest being grass; he will have to pay R1,600 + 400 as. (or in all R1,625) for the next 30 years; and yet, at the end of five years he may not have more than 60 acres worth keeping up; he will then have to choose between totally abandoning this 50 acres and losing the whole sum originally invested, or going on paying the whole tax for twenty-five years longer. On the other hand, in the somewhat unlikely event of a new "coffee-boom," a proprietor of 1,000 acres of jungle, which would now be assessed at 2as. per acre (R125), could open the whole in coffee, and only pay that sum for thirty years against his neighbour's R1,625 for 50 acres. Or again, a large proprietor might now decide to abandon 1,000 acres of doubtful coffee on a group of estates, have it (as I read Mr. Stuart's letter) classed as "unassessed waste," and a week after the conclusion of the settlement plant it up, as Ceylon men have done, with tea or fibre, and not pay an anna on it. The inequality is so glaring, and the loss to the revenue would be so great in the multiplication of such cases (for of course the first instanced proprietor would have to abandon his 50 remaining acres), that it is possible the plan will be modified. It may be thought that I have proved too much for my case, and that the benefit to the second and third planters would counterbalance the injury to the first; but in reality, while the last cases suppose a state of prosperity that does not exist, the first will be the position in which large numbers will inevitably find themselves. A reasonable suggestion, which might be made at the intended meeting, would be to tax all the coffee land at R2 for the present, and on its being decided to abandon any part of it, to oblige the proprietor to have the part surveyed by some competent person, and a declaration made before a magistrate, if considered necessary, of the correctness of the measurement, and then to reduce the tax to 2 annas per acre; this plan, while not interfering with the general principle of Government referred to above, and enabling it to do away with its present staff of surveyors, would allow planters to keep up doubtful land for some years longer, and would save a considerable present loss to the revenue; for, if carried out in its integrity, the system favored by the authorities will compel us to abandon every acre that does not seem likely to last. Mr. Stuart, in one of his letters, trusts we "will abstain from giving credence to rumours circulated by persons interested in the continuation of chaos," so until he has had an opportunity of stating the exact course that will be pursued I need only allude to two of the most persistent of these rumours, namely, those that credit Government with the intention of imposing a stamp fee on felling forest trees, and of making reserve forest of all escheat land not already taken up for planting or mining. If either of these proposals were carried into effect, the result would be most disastrous, and it is to be hoped they are not seriously contemplated.

The dullness of the London coffee market, has had a most distinct and depressing effect out here, and this is the more provoking because crops in Wynaad promise to be a good deal above the average both in quality and in quantity.—*Madras Mail Cor.*

TEA YIELDS AND TEA AVERAGES.

To the Editor of the "Times of Ceylon."

Sir,—As I am reported to have asserted that I have a preference for a high yield and low average rather than a moderate yield and high average, I beg to deny the assertion. I agree with both "Festina Lente" and "Humko Malum" in what they have written. I believe in plucking carefully, and aiming more at getting good leaf than a large quantity per cooly. I believe in taking the leaf when ready, withering carefully, and fermenting evenly, drying without burning, and packing tea in a well-prepared state. I believe in watching my trees to see what treatment suits them best, and, because Tom and Dick are bringing in so much leaf per cooly, I don't bring in my bushes to try and keep up with them. There is far too keen a desire to try and make so much off young trees because on one particular estate 300 or 400 lb per acre was made in the second year, and of course everyone ought to be able to do the same. I believe in a man being satisfied with 300 to 400 lb good tea per acre with good average. It sometimes happens, however, that even with tea made in the most careful manner good prices are not got. This, of course, is a case of Paul may plant, &c., yet he cannot put into the soil what is required to make the tea suitable to the palate of the Lane brokers. I believe in manure when tea gives a fair quantity but is wanting in strength. C. A. HAY.

Blackwater Estate, Jan. 22nd.

THE LIBERIAN REPUBLIC.

"THE REPUBLIC"—PRODUCE—NEGROES—SETTLEMENT—PROGRESS.

(FROM A ROVING CORRESPONDENT OF THE "TIMES OF INDIA.")

HARPER, LIBERIA, 3rd Nov.—I informed you in my last letter that I was about to visit the "Black Republic," and then anticipated some interest from the trip, an expectation which has been completely realized. The negro is necessarily an object of interest in whatever part of the world he may be found, of amusement when he claims an equality, intellectual, social and physical, with his white brother; and certainly of interest and amusement combined and intermingled when he sets up a republic of his own, founded upon principles of freedom and perfect equality, and administered upon principles of oppression and injustice to the aborigines of the soil. I suppose most people know that Liberia was purchased by the Americans from the native chiefs who possessed that portion of it which adjoins the sea about forty years ago as a colony for emancipated slaves from the States, and the Government was almost immediately handed over to the negroes themselves, our Yankee friends being too wise in their generation to saddle themselves with a Liberian protectorate. I was, therefore, anxious to visit this "Yankee Doodle" state to arrive at some satisfactory conclusion on the much-vexed question as to the capacity of the nigger for self-Government, and also to investigate the manner in which these descendants of slaves and exiles from slavery treated the native races whose soil was bought or taken from them, and whose territory they were colonizing. On the passage to Liberia along the shores of the "no man's land," which intervenes between the Gold Coast Colony and the Black Republic, I was much interested in seeing twelve or fifteen English merchant barques at anchor at different points along the coast, and learning that they were verily and indeed the lineal descendants of the British slave ships which a century or so ago used to make sad havoc among the inhabitants of these parts. These vessels are owned by the same firm who were at that period most largely engaged in the slave trade, and are still the survival of a peculiar and antique sort of trade quite refreshing to come across in these days of coffin steamers and civilized commerce. These floating warehouses fill up in England with a mixed cargo of cloth and beads, rum, gin, salt, tobacco, gunpowder and firearms; the ship then sails for the West African Coast, where these articles are bartered for gold-dust, palm oil, ivory, kernels, and any other small articles which can be obtained from the natives. This produce is sent home, as obtained, by the mail steamers, until the original cargo is exhausted, when the vessel departs for Bristol to fill up afresh. Steaming along the Liberian coast, as monotonous with its densely covered bush, eternal green and flatness as is the Gold Coast, I proceeded first of all to the port of Grand Bassa, one of the principal in the Republic and in close contiguity to Monrovia, the capital, and called after the American statesman of that name. Grand Bassa possesses a fine bay, but an extremely shallow one, with rocks springing up here and there all over it, and, consequently, intricate in the extreme and difficult to navigate. There are three settlements or "towns" at Grand Bassa parted by narrow walls of jungle, called, respectively, Edina, Upper Buchanan, and Lower Buchanan. If the former was named after the abode of our first parents, the explorer or builder, or whatever he was who so christened it, must have been of a decidedly facetious and sarcastic turn of mind and fond of his little joke. A fairly wide and deep river, the St. John, navigable, as far as regards depth is concerned for some distance inland, runs into the sea at Upper Buchanan, but it has a bar famous for surf and sharks, over which it is impossible for even a boat to pass except at the very highest tides. This is the great drawback of all the West African rivers. For hundreds, nay thousands, of miles along this coast there are innumerable wide and deep rivers rendered utterly impotent for navigation or trade by the impassable bars at their months. All these towns occupy holes in a curtain of the densest and tallest greenery. They are composed of groups of scattered white-washed houses, half of them looking like chapels and the other half resembling toys, in close adjunct to which are the brown huts of the natives, or "the heathen," as they are charitably, fraternally, and amusingly dubbed by the "Liberians." Whatever these latter have done for their adopted country—and I am sceptical as to either the amount or value of their work—it is quite evident they have not succeeded in ingratiating themselves with the aborigines of the territory they inhabit, who openly despise them, and dispute their authority successfully over the whole of Liberia except at the ports, where there are a few soldiers or policemen to restrain their propensities in this respect. The rulers of this contemptible State claim no less than twenty-six parallelograms stretching inland at various angles with the shore, and stated to have been acquired by conquest or purchase between 1822 and 1827; but the natives complain that having in the first instance welcomed their brothers in blood amongst them, the latter have despoiled them of their possessions, and that, when possible, from having been once lords of the soil, they have sunk to the position of mere serfs. It is not, therefore, difficult to understand why bad blood exists between these two classes of negroes, and why outbreaks and "revolutions" are a constant occurence. There are no Englishmen in Grand Bassa, nor, as far as that goes, in the whole of the Liberian Republic, with the exception of a solitary individual at a place called Labori, who is a regular thorn in the side of Liberian officials, and of whom I shall have occasion to speak later on. The British Government do not even maintain a minister, consul, or agent of any kind in the country. The nominal duties of consul are performed, or supposed to be, by the Governor of Sierra Leone. There *are* some British subjects resident within Liberia, black men from Sierra Leone, both at Grand Bassa and the other parts of the Republic, but I believe they do not find that they are quite as free in this free country as they are under monarchical rule at Sierra Leone. They complain bitterly and loudly of the unrepresented state of the country, of which they are subjects in this Republic, and aver, that in consequence thereof, they are unable to make their legitimate grievances fully and fairly known, and that the Liberian officials take advantage of the fact. I do not suppose it is very generally known that at the present time Liberia is a closed country to foreigners quite as close as China. There are only five ports in it now open to trade, and foreigners are forbidden to erect factories for trading purposes in the interior or even to proceed outside the immediate neighbourhood of these ports. What the object of the Liberian authorities in carrying out this rigorous policy of exclusion may be I know not, but there can be but little doubt that by so doing they are preventing any advancement in the material progress of the country. At the present time the revenue of the whole of Liberia only amounts to £25,000 per annum, most of which is levied by extortionate taxes on the foreign community at the trading ports. As the country has a coast line of about 300 miles, and possesses much internal wealth, the paltriness of this revenue is at once apparent. As a natural consequence of this the Liberian "army" consists of merely three or four hundred men, who can only by the exercise of the most vivid imagination be termed "soldiers," as they are badly armed, badly drilled, badly disciplined, and badly—exceedingly badly—officered. Liberia as claimed extends an hundred miles or so inland. Liberia, where Liberian authority runs, is a very vague country, extends but a very few miles from the coast, and is by no means continuous along that. And yet Liberia, like some other countries similarly situated, is everlastingly endeavouring to extend the nominal limits of her territory, and claims both her northern and southern boundary to stretch beyond the limits that Great Britain recognizes.

There are only two Europeans at Grand Bassa, both Germans, the representatives of a Hamburg firm. They complained exceedingly of the extortionate taxes levied by the Liberian officials, one item of which was an impost of £400 before permission could be granted to open a trading factory, while every article imported is liable to a heavy and practically prohibitive duty. The exports from Grand Bassa at the present time are almost entirely confined to palm-oil and kernels. And yet the whole country teems with productions of every kind, and might be made to grow anything. In the neighbourhood of Monrovia coffee and Indiarubber are grown and exported to a certain extent, and Liberian coffee has obtained such a high name in the English and American markets that there

can be little doubt that there is a large field for native industry in this direction, and foreign capital too, if the Liberian Government would only encourage the immigration of foreigners and the development of the country. Gold is believed to exist in large quantities in the interior, and a considerable amount of it is from time to time brought to the coast by the natives. Other minerals are also known to exist in the country and are believed to be considerably and extensively spread throughout the country. Until the force of circumstances or the annexation of Liberia by a European power—in my opinion a not at all improbable event in the future—there is not, as far as I can learn, any chance of steps being taken by Liberia's present rulers to develop her material or mineral resources. Germans are now found at all the ports, the visits of German men-of-war have been frequent of late, and I shall not be surprized to hear some day that the oppression or ill-treatment of some German subject has formed a reasonable pretext for German interference and ultimate annexation, which will be a good thing for the world, however unpleasant it may and undoubtedly will be for the Liberians. The total absence of Englishmen in the country I attribute to the heavy taxation, the absence of British consuls and the limited amount of trade that exists under the present régime. Englishmen do not, as a rule, care about residing in unpleasant or inhospitable climes unless the pecuniary inducements to do so are in proportion, whereas the German is contented with very moderate competency.

HARPER, LIBERIA, Nov. 11th.—The shores of this part of the world present a solitary and somewhat melancholy appearance. Eternal bush is all that meets the eye, while not a sail is to be seen anywhere as far as the eye can reach. What a contrast this to the eastern shores of Africa, the Red Sea, or the Persian Gulf, where although, perhaps the inhabitants are but little further advanced in the run of civilization, and in some parts not so much, they are certainly more addicted to seafaring pursuits, and the picturesque dhow with its varied cargoes—sometimes human—gives variety and life to the scene. There are no towns of any size between Grand Bassa and Harper, but merely a few villages scattered at intervals along the coast, and a run of 180 miles from the former place brings one to this the second town as regards size in the Republic of Liberia. Harper is situated on Cape Palmas. This bold headland which received its name from the Portugueae poet Camoens from a solitary clump of palms on it, which still remains and is therefore an object of interest to the traveller, is a hundred feet high, half a mile broad by a quarter of a mile long, and forms a harbour immediately opposite the town, which if not "the finest in the world" is certainly sufficiently commodious and affords ships cruising in this part of the world a pleasant change after the eternal rolling and surf of the west African shores. The town looks uncommonly well from the sea. The church spires of the Episcopal, Wesleyan and Presbyterian denominations peep out from amongst the trees, and the shingle-framed houses of the Liberians surrounded by gardens add picturesqueness to the scene. Harper possesses, besides the three churches I have mentioned, an academy, a hospital, an orphan asylum, and a lighthouse. The latter is more of ornament than use, as the Republic cannot afford funds to keep it constantly lighted, and mariners are therefore advisedly warned to place no reliance on it. In the face of it the Government insists on the mail steamers conveying the mail to and from the country without any subsidy "in lieu of harbour and lighthouse dues," though not a penny is now spent on either harbours or lighthouses. Adjacent to Cape Palmas' lighthouse is the flagstaff which bears the Liberian national flag, the same as the American ensign, with the exception that instead of many stars there is only one.

This country is certainly a more valuable one in every way than our Gold Coast Colony: it possesses some three or four fairly good harbours, whereas the latter cannot boast of one. There is, moreover, an absence of that terrible surf which makes landing or the transference of cargo frequently impossible, and at all times difficult and unpleasant on the shores of that colony, while the country itself appears to be more productive, to have greater mineral wealth, and to "tap" a more valuable part of the Dark Continent.

NETHERLANDS INDIAN NEWS

(Translated for the "Straits Times.")

THE RAILWAY AND SUGAR PLANTERS—CINCHONA

The *Locomotief* of the 3rd January states that the firm of Dorrepaal & Co. has been merged into a bank bearing that name, the capital for that purpose having been fully subscribed and the articles of association published in the Government Gazette. The Netherlands India Railway Company, to meet the wants of sugar planters, has consented to lower by half a guilder a picul its charge for carrying that article to Samarang from Djockdja, provided growers availing themselves of the reduction agree to send all their sugar crops by its lines of rail.

The Batavia *Dagblad* of the 2nd January states that the success attending cinchona cultivation in Java and India has led to raising that product being also undertaken by Portuguese in the Cape de Verde islands and St. Thomé.

COFFEE AND TEA PROSPECTS.

Colony coffees are destined to become very scarce and valuable, and it is to be hoped that planters will not too rashly kill the goose (the tree) that has already laid a good many golden eggs; but will remember that many who perhaps may be in a better position to form an opinion on the subject than themselves, verily believe that with fair seasons this goose is on the verge of laying a good many more golden eggs. We speak, of course, of coffee in fair condition, planters cannot do better than preserve to the utmost any coffee that show vigour and stability. If as some suppose the maximum yield of coffee has already been attained in the world, they will do well to consider that no fresh country can quickly rise into competition against them, and the conditions (such as virgin forest) and risks of growing coffee are so peculiar, that it becomes one of the least of likely agricultural pursuits, to which capitalists and others would now care to devote their money and attention. A strong objection urged to maintaining both tea and coffee cultivation on an estate is the expense of keeping up two sets of buildings. This objection is already partially overcome by the local demand for green leaf, which is beginning to spring up in the young tea districts, from proprietors of Central Factories and this is a feature of the greatest importance to planters as it helps them to postpone the inevitable expense of tea manufacturing machinery, until their plantations are more forward, and their resources more defined, and enables them to still keep and cultivate areas of coffee which, as we have already shown may become very valuable again, and which possibly if, planted up with tea would not prove so remunerative as if kept in coffee and well-cultivated.

JAMAICA PROPERTIES.—A very large and influential East India Firm in London, has asked us to procure a list of Jamaica properties which are now, or may be at any future time, for sale, with particulars and the price asked. The reason given for this request is, that retiring East Indians are often desirous of investing their capital in real estate; and the opinion gains favour in London, that Jamaica is a promising Colony and has a climate well suited to old residents in the East, The Firm we speak of is at present providing large properties in Australia, in New Zealand, Manitoba and Texas; but they say information about Jamaica is extremely difficult to procure, and what there is is very unreliable. We have engaged to keep the firm informed and to post them such particulars as may be sent us for registration in this office. We commend the subject to the thoughtful consideration of those having properties which they wish to find purchasers for.—*Gall's Weekly News Letter.*

THE DATE PALM.—We have on various occasions alluded to the culture of the Date Palm at Bordighera and other places in the Riviera for decorative purposes. The leaves are tied together, and thus blanched, and after drying are gilded and used on Palm Sunday and other festivals of the Roman Church. But besides this, which was, we believe, the primary use to which they were put, the leaves are now largely used in the manufacture of ornamental baskets and similar elegancies.—*Gardeners' Chronicle.*

GRUBS INJURIOUS TO COCONUTS are thus noticed in the *Fiji Times*:—

There is a grub—called by the Fijians *mimimata*—which has done considerable damage to some coconut plantations on this end of the island. It fastens on the leaves and eats off all the green and of course affects the vitality and fruit yielding power of the tree. A good way of getting rid of them is to light innumerable fires beneath the trees when rubbish is not too dry and is likely to produce more smoke than fire, and the smoke will drive the grubs all out of the trees. The experiment has been tried with success on some plantations.

MR. D. MORRIS IN JAMAICA.—The Rev. Dr. Johnstone of Brown's Town has made a deep impression on the minds of the people of Edinburgh by his Lectures on Jamaica, while there in August. Another gentleman, following his example, has been lecturing there on New Zealand, with the object of inducing immigration in that direction, and he is being successful. Would it not be an advantageous move on the part of our Government to send our talented and highly popular Director of Public Gardens and Plantations on a Lecturing tour through England and America, taking with him wax specimens of our Fruits and Flowers, Views of the Island, and a collection of Curios to illustrate his subject and so direct and assist emigrants to Jamaica? He has the power of interesting an audience, of communicating his ideas and truths in a very popular way, and our opinion is, from what has been done already, that Mr. Morris might be most profitably employed as an advocate abroad, and so increase the chances of our future prosperity. We trust the subject will not be allowed to drop out of thought.—*Gall's Weekly News Letter.*

THE RIO COFFEE CROP ESTIMATE is thus dealt with by the *Rio News*:—The *Associagao Commercial* telegraphed to New York and to Havre on the 9th and 10th inst, that there had been no change in the coffee crop estimates for the present season. This telegram was so evidently asked for from the two markets in question, that we have again had our attention called to the matter and it appears that in some instances the estimates have been increased. We are somewhat at a loss to explain the divergency in opinions and can only lay before our readers what we have been able to gather upon the subject. A majority of exporters, we believe, have not altered the original estimates, for the following reasons: that last year's crop was so nearly estimated in advance that this season's may be conceded to be in the same case; that the large receipts are directly attributable to the state of the money market, through which planters have been obliged to market their crops as quickly as they could be prepared; that, as was not the case last year, factors have, as a rule, urged the planters, to market their crops and the planters, having seen the unfortunate result of the syndicate, have given up their hopes of any return to high prices and are complying with the factors' suggestions, and finally that the argument, that the free receipts are attributable to an error in the estimate, may be met by the reply that the crop may be two thirds exported during the first half of a crop year from the increased facilities now possessed by the coffee producing provinces. On the other side it may be said that when erroneous, the errors have invariably been in under-estimating the crops, and if last year's crop was correctly calculated many instances can be produced where estimates have been utterly unreliable; that planters have hardly ever acknowledged that a growing crop was anything more than fair (*regular*), and that the consuming markets seeing average receipts of over 13,000 bags to continue steadily will be suspicious and unbelieving. We can hardly dare to express any opinion in a question where those so closely interested in it diverge in their opinions. It is certainly true that *wolf!* has been so often the cry of the planters, that consumers show incredulity and are prone to believe in any increase of the crop estimates, but it is no less true (if the fable is reliable) that the wolf finally came; also that the facilities for obtaining reliable information regarding the crop have improved is undeniable. Altogether the question is one where argument is of little importance; both sides cannot be right and as the increased estimate for the 1884-85 crop adds only 500,000 bags, and we are nearly half through the season, an uninterested party would think, that beyond the very natural desireto have made correct estimates this quantity could have no very serious effect upon consuming markets, nor upon Rio houses. The majority we repeat favor the original estimate of 3,500,000 bags.

THE OUCHTERLONY VALLEY COFFEE ESTATES, amongst the best and most profitable in the world before the advent of leaf-disease, are thus noticed in the *Madras Mail*:—The Administrator-General of Madras stated at the High Court, Madras, on Monday, that last year on the Ouchterlony coffee estates nearly 2½ lakhs of rupees were spent, while the profit only amounted to about R1,25,000. That amount of profit is surely very good; but we suspect gross return from crop is meant?

THE EXPORT OF PARCHMENT COFFEE FROM BRAZIL to the United States, probably, seems to be assuming importance, judging from the following paragraph in the *South American Journal*:—"The Minister of Finance had announced that coffee in the hull will be allowed shipment, paying duties as good coffee, and that a deduction of 16 per cent will be allowed on the weight. He instructs the collector at Rio to prepare two tables, for summer and winter respectively, as the weight varies greatly with the season of shipment."

SEED TESTING.—At the New York Agricultural Station an apparatus is used as follows:—A 12-inch square earthen seed-pan is filled with a fine sand, pressed in, and the surface properly smoothed. This seed-pan is then placed in a copper tray 1 inch deep. Over the seed-pan, and fitting within the tray, a copper box with a glass cover is placed. The seeds, generally one hundred of a sort, are carefully counted and placed in parallel rows upon the surface of the sand, and left exposed to observation. Water being supplied to the tray capillary attraction keeps the sand in the seed-pan evenly moistened, while evaporation keeps the air within the apparatus and in contact with the seed thoroughly saturated. Each day the rows of seed are carefully gone over, and such seeds as are found germinated are counted as they are removed.—*Gardeners' Chronicle.*

IMPATIENS HOOKERIANA.—Notwithstanding the beauty of the flowers of this species, and the fact that they are generally considered the largest of any, we seldom hear of its being successfully flowered in this country. Compared with I. Sultani and I. flaccida it is evidently not very floriferous even in Ceylon, its native habitat. The two latter, and I. Sultani especially, will flower in a small state either from seed or cuttings, but the species under notice must be grown to a considerable size, and towards the end of summer subjected to a ripening process by full exposure to light, with merely moisture sufficient to prevent flagging. The fleshy stems under this treatment will be induced to plump their flower-buds, which will flower well into winter. The blossoms are pure white with blood-red dots and lines on the two lower petals. The white spur is curved and remarkably attenuated. There is a figure of the species in the *Botanical Magazine*, and well flowered species may be seen in the Begonia-house at Kew.—*Gardeners' Chronicle.*

CABBAGES.—This has been a very bad year for cabbage-growers in New England. In one field in Western Massachusetts, ten thousand heads were not harvested because nobody would offer a cent a piece for them. Great quantities have been stored, awaiting a demand. How to hold cabbages safely, is a question which Eastern farmers would greatly like to hear answered.—New York *Hour*.

TOBACCO CULTIVATION AND PREPARATION IN DUMBARA, CEYLON.—Among local industries, the cultivation of tobacco has long occupied an important position among the natives, more especially of Jaffna, Uva and Dumbara, Europeans have only now and then taken the matter up, and generally to drop it again very soon. Poor "R. B. T." tried to introduce Dumbara cigars on an extensive scale into the home market, soon after he had made a hit with "cocoa," but he dropped a good deal of money in the unsuccessful experiment. Still, that Dumbara can turn out good tobacco and well-made, well-flavoured cigars has been incontestably proved as anyone can testify who has seen a box with the well-known mark,—

DUMBARA CIGARROS

Fabrica De Tabacos

JIH

CEYLON

MELBOURNE EXHIBITION 1880-81—MEDAL.

Many will wonder that a more extensive trade in Dumbara cigars has not sprung up, considering the facilities in labour carriage, &c However, we trust, the pioneer, an old and esteemed resident Mr. Ingleton, may continue to have all the success he can desire.

DEPRESSION IN BRAZIL.—The *Rio News* writes :—The silence of all the local papers regarding financial troubles among some of the factor houses here is a somewhat difficult matter to understand, for the *Jornal do Commercio* publishes the announcement of the disappearance of the manager of one of these firms with the declaration that two persons interested in the business would take charge of it until the arrival from Europe of the head of the house. It has moreover been the subject of general conversation in the street and at the Exchange and names are freely mentioned of other firms in difficulties. That difficulties were imminent to those whose resources were seriously compromised with the planting interest was clearly apparent to all who were not deaf to the constant complaints of city dealers of delays in getting in money from their debtors in the interior, causing all who could to curtail their credits, and the advice offered the planters to reply to the Dantas project by refusing to pay their debts; although this was hardly considered serious may have been more so than was at the moment thought. Another point on which no comment is made, is that very considerable sums have been remitted to Europe, even at the present low rate of exchange and that these remittances are not for the purposes of trade but are withdrawals of capital employed in the country, whose owners seem hopeless of any improvement and have therefore determined to have their capital invested in some form less subject to the fluctuations which we see in Brazilian investments. The difference in the income of a person living abroad with his capital invested in currency securities here is very severe and no surprise can be felt that such capitalists as are in a position to do should endeavor to make their incomes rather more stable than can be hoped for from Brazilian securities bearing interest in currency, for some time to come. We are apparently to see a gloomy closing for this already sufficiently unsatisfactory year, and all that we can do is to express a hope that the new year, the new Chambers and a new financial policy will all aid in improving the outlook after the turn of the year.

INDIAN PAPER AND PAPER MILLS.

The Government of India's expressed desire to enter into contracts for the supply of Indian made paper has already produced the result of stimulating to an encouraging extent, the paper industry of the country. The Bally Mill in Calcutta, although established but a few years since, already pays a good dividend, its shares being valued in the market at more than fifty per cent their original value. The enterprise of the good people of Calcutta in this direction has led them to establish recently another mill called the Titaghur Paper Mill Company. The paper manufactured by the former is of so good a quality that it is used by one or two of the daily papers in the metropolis. We observe that a company is to be formed in Poona, the originators of which have issued a printed prospectus. We are informed that cheap labour and water will be abundantly obtainable for the carrying out of the processes incident to the industry. At the head of the proposed company is H. H. the Chief of Kajal and Regent of Kolhapur. The prospectus referred to furnishes certain statistics bearing on different points connected with the trade in paper in the presidency of Bombay. The total value of the different sorts of paper imported into Bombay amounted in 1880-81 to nearly nineteen lakhs of rupees. In the last official year the imports amounted to the value of rupees sixteen millions, seventy-eight thousand, four hundred and nineteen. The Collector of Bombay has supplied to the projectors of the Poona Paper Mill Company, the information that the cost of the stationery obtained by Government in 1881 was R1,75,000. The Government of Bombay has accorded the promise of every encouragement and assistance to the Directors of the company. It has intimated its willingness to take into consideration any proposals the Directors may make with a view to a contract being entered into with them for a supply of paper for five years, on its being established that they can make and supply paper of as good quality as that now used.

As for the materials required for the manufacture of paper in Indian Mills it is well-known that the supply is abundant, hundreds of tons of rags are exported from this country to England representing in value a round sum of rupees. But the paper manufacturers in Europe do not look for the largest supply of their raw material to this source. It being found to be expensive, manufacturing ingenuity discovered other things that, while cheaper, are just as suitable. Grasses and vegetable fibres are very largely employed and some of the finest paper is but the outcome of the resourceful skill of scientific manufacturers in the manipulation of materials of this description, which are abundant in many parts of the country. On the authority of certain experts and chiefly that of the Superintendent of the Botanical gardens at Gunesh Khind it is stated that for the supply of fibres of the sort needed for the manufacture of paper there is no reason to apprehend that the material will not meet the demand for it. The Indian bulrush, according to them, grows very freely on the Bombay side, and from it paper has been made by native manufacturers in Poona. It is calculated that it can be grown at so low a price as rupees fifteen per ton of dried stems.

Poona, it is declared, is favorably situated for the working of paper mills. There exists a sufficient quantity of water got from the Khadakwasla canal, and in other respects, so far as an opinion can be formed from the figures and statements in the prospectus of the company, its success is assured. What is a satisfactory feature in the introduction in a new field of a promising industry is the lively interest taken by the Government of Bombay in the movement. In the Bombay presidency there are already two paper mills at work but they have hitherto turned out only brown paper for wrappers and paper of an ordinary quality. Yet withal they are paying concerns like those in Calcutta, Gwalior, and Lucknow.

No serious attempt has been made in this presidency to revive the paper industry of the country by the methods and scientific appliances employed by European manufacturers. There is any quantity of cheap labor, and no difficulty need be expected if the field of operations is judiciously chosen in regard to the supply of water. That the necessary capital and enterprize are available is evid-

enced by the circumstance that native capitalists in this presidency have, in certain instances, combined their resources in resuscitating a few industries for which the country was once famous. In all projects of the kind it is of importance, and indeed necessary that there should be a small body of influential men who are willing to pilot an undertaking that gives much promise of success. Of course one of the requisites necessary for the right undertaking of an industry which has no possibility of succeeding if it is not conducted upon European methods, is the employment of skilled European artisans to do the duty of supervision and direction. Such has been the experience of the cotton mills, which, year by year, are growing in importance. The cost of the machinery imported is, in many cases, large but as we have seen, in the case of the paper mills in Calcutta and Bombay the cheaap labor procurable in India can be brought, under skilled European guidance, to utilize the most complicated and difficult styles of machinery. It is to be hoped that capitalists in this presidency, who are influenced by a spirit of enterprize, will soon follow in the wake of those who have, in few instances and successfully in the other presidencies, added the paper industry to the list of industries that are being revived and developed in various parts of India. It may be expected that the Madras Government will be as ready to give its encouragement and countenance to any well-devised scheme for the establishment of a paper mill in this presidency as the Government of Bombay has done in respect to the Poona paper mill company.—*Madras Standard.*

LATE DEVELOPMENTS IN THE COCOA MARKET.

It was to be foreseen that after the capture of Guayaquil in the summer of 1883, followed by the pacification of Ecuador, the chief cocoa-producing country, the price of cocoa under a restoration of regular supplies from there would decline materially in spite of increased consumption in the United States. In all probability, the decline since then would, however, have been less rapid but for the impulse which the former high ruling of the article had given to production in the Valley of Amazon and in Bahia, Brazil.

On January 1st, 1883, Guayaquil cocoa was worth in New York 13½ cents, on December 1st of the same year, 18½ cents; on May 17th, 1884, 16¾ cents; and on October 22nd of the same year 14¾ cents—a decline of 20 per cent in about eleven months.

The cocoa crops of Ecuador of late years have been as under:

1879	quintals	302,490
1880		332,980
1881		207,286
1882		196,580
1883		146,700

1 quintal weighs 101½ pounds English.

The shipments from Guayaquil were 16,616,460 pounds Spanish in 1883, of which Peru received 64,974; Chili 158,109; Spain, 4,582,001; France, 2,286,487; England, 3,061,896; the United States, 1,214,274; Mexico, 411,185 Colombia, 1500, the Argentine Republic, 3,750; Germany, 4,630,146; Central America, 150,938; Uruguay, 28,700 and Italy, 22,500. This enumeration shows how widely this sort of cocoa is distributed, and the important part it necessarily plays in a full crop year like that of 1880. The tendency in Ecuador has been to again produce normal crops, while in Brazil, Para alone has turned out this year 63,000 bags, for which Nantes and Bordeaux in France compete. In August alone, three vessels were loaded for Nantes with 12,200 bags; and in September, as much was taken for the same destination. In Bahia, the supply has been as liberal; in September, half-prepared was selling there at 8,300 to 8,500 reis the arrobe, equal with exchange at 19⅛d. to 58s. 11d. à 60s, 2d., cost and freight, per hundredweight. Another important cocoa-producing country, especially for the American market, is the island of Trinidad in the Gulf of Para, opposite the northeastern coast of Venezuela, turning out about as much cocoa as the United States annually consumes. The campaign had about terminated there when the last mail left Port of Spain on September 26, and the new crop will begin to be gathered this month. Meanwhile, there has been an active American demand for remnants of the 1883—84 crop at $14·50 à 15·50 the fanega of 110 pounds Spanish, 100 pounds Spanish being equal to 101½ pounds English. There was exported from Port of Spain from January 1st to September 26th, 12,200,815 pounds English against 10,930,320 in 1883 and 10,872,773 in 1882; in other words, Trinidad also furnished a full supply. In other South-American countries, Colombia and Venezuela, for example, and in Mexico, Hayti and minor centres of production, the local demand is so considerable, that there remains comparatively little for export; Mexico has, indeed, at all times been more of a consumer than producer. Spain and France are the greatest cocoa-consuming countries in Europe. According to the *Memorias Commerciales* of Madrid, Spain imported during the first six months:—

The foregoing shows that Spain draws its chief supply from Guayaquil.

The import of cocoa into France during the first eight months has been.

	Francs.		Francs.
1884 - - - -	15,575,000	1879 - - -	15,813,000

1880 - - -	11,875,000		

It will be noticed that the increase since 1877 has been considerable.

The United States imported during the fiscal years ended June 30.

1883 ...	9,030,724 pounds... ...	$ 1,125,566
1884 ...	12,235,304 „	1,644,766

The increase of importation during a twelve month has, therefore, been no less than 36 per cent in weight. As we are now on the eve of the active season in cocoa, and the supply is scanty, the market has of late shown great firmness at the moderate prices ruling.—*Indian Mercury*

INSECT PESTS: HEMIPTERA.

Hemiptera (Gr. hêmi, half and ptcrón, wiug), an order of the *Insecta* most commonly known by the name of "bugs," and containing the species so well known to infest houses. In their earlier stages they have what is known amongst naturalists as an incomplete metamorphosis; that is to say, after quitting the egg, and during the two stages of their existence before assuming the perfect form, they move freely about, thus unlike the *Lepidoptera*, &c., whose pupa state, or that preceeding the perfection of the insect, is quiescent. When the transformations have been completed, the insect generally possesses four wings. The superior pair, or hemielytra as they are called by authors, are attached to the mesothorax, and are composed of two substances,—the basal portion coriaceous, or resembling leather, and the apical one membranaceous, or resembling thin, transparent parchment. The lower pair are attached to the metathorax, and are entirely membranous and generally transparent, and capable of being folded when the insect is in repose. This segment of the sternum likewise bears on each side, anteriorly, a more or less reinform-shaped orifice, within which lies a sac containing the fluid or matter from which so many of the *Heteropterous* portion of the order emit a most disagreeable odour. They also possess in all stages a mouth (rostrum) composed of three or more joints formed for suctorial purposes.

The order is divided into two sub-orders, *Hemiptera-Heteroptera* and *Hemiptera-Homoptera*, and these again are separated into divisions and subdivisions, the latter being distributed into families which contain the various genera and species. In the first sub-order (*Hemiptera-Heteroptera*) there are two divisions, viz., *Gymnocerata* and *Cryptocerata*, and the families comprised under these heads are 69 in number, the following being the generally accepted order in which they are arranged, viz.: *Pachycoridæ* (in this family the scuttellum is so enlarged as to cover the whole of the upperside of the abdomen, both pairs of wings being concealed beneath it when not in flight; in one genus at least the species might be mistaken for some of the *Buprestidæ* in *Coleoptera*, which they resemble in form and brilliance of colour), * * * *Phlœidæ* (this last contains but one genus, the species of which are most peculiar in appearance, as they resemble small, thin pieces of bark joined together), * * * *Nabidæ* (the species comprised in the last 12 families are predaceous in their habits, and the larva of one species, *Reduvius personatus*, is known to prey upon the common house bug, *Acanthia lectularia*; some two or three of the species in South America are also known to live with spiders), * * * and *Notonectidæ* (the species pertaining to the last eight families, except the *Galgulidæ*, live either in or on the water, and the genus *Belostoma* contains the largest insect of the order, *Belostoma grandis*, which measures 3½ inches in legth by nearly 1½ in breadth). In the second sub-order (*Hemiptera-Homoptera*) there are three grand divisions, viz., *Cicadina*, *Phytophthires*, and *Anoplura*. The first embraces the families *Stridulantidæ*, *Fulgoridæ*, *Tettigometridæ*, *Membracidæ*, and *Cicadidæ*; and in these families are to be found perhaps some of the most curious and wonderful forms of insect life. The well known lantern-fly (*Fulgora laternaria*, L.) belongs here, and the whole of the stridulating or singing group is also included. The *Phytopthires*, or second division, contains three families, viz., *Psyllidæ*, *Aphididæ*, and *Coccidæ*. None of the insects composing this group are of large size, and many of them are only about one line in length. The first family affects trees and plants, in many instances distorting the leaves and buds; one of its species, *Rhinocola speciosa*, has been recorded by Lichtenstein in the annals of the French Entomological Society for 1872 as puncturing poplar leaves which afterwards attain the size and form of a cucumber. The *Psyllidæ* differ from the second family in having the power to leap, their third pair of legs being formed for this purpose. The *Aphididæ* are perhaps best known by the terms "blight," "green fly," &c. These are to be found almost always in large companies on nearly every kind of tree, plant and shrub. They are said to produce the honey dew found upon maple and other trees, although this has been disputed by Dr Hooker in the *Gardeners' Chronicle* for July 1873. They are furnished with two setiform pipes or tubes, varying considerably in length in the different species, placed one on each side of the abodmen on the fourth segment from the apex, from which certainly is emitted a sweet fluid which the ants are well known to follow them for and consume. This family also contains the great vine-pest known by the name of *Phylloxera vastatrix*. The third family, *Coccidæ*, has amongst its members the well-known cochineal insect (*Coccus Cacti*), from the female of which when gathered and killed is obtained the drug or dye used in giving the red colours, scarlet and crimson, It is also used for making carmine. The last division to be dealt with is called the *Anoplura*, and contains the most degraded forms of the whole order, viz., the lice, the fullest information concerning which may be obtained by consulting the works of Nitzch, Burmeister, Leach, and Denny.

Although the *Hemiptera* are of very ancient date, remains of some of the fossil forms having been found in the Primary and other formations, the number of these is but few; they are enumerated in a paper on "Fossil Entomology" by Mr H. Goss in vol. xv. of the *Entomologist's Monthly Magazine*.

The whole of the group is extremely widely distributed, being found in almost every portion of the globe; and they are very varied both in form and in their modes of life,—man, animals, birds, insects, and plants being subjected to their attacks. On the Continent they have for a long period engaged the attention of naturalists, but in England little was known of the actual number inhabiting these islands until Douglas and Scott in 1865 published their volume of *British Hemiptera-Heteroptera*. In 1859 Dr A. Dohrn published what may be considered to be the first whole-world catalogue of the order; and, taking it as a basis, for there is no other approximate list, and adding a reasonable amount of new species collected in each year since that time, their number would amount to nearly 10,500 species, 5,300 belonging to the heteropterous section and the remainder to the second sub-order. Out of these Europe lays claim to at least 3000, whilst Great Britain is known to possess not fewer than 1000. There is no record of any one of the species being cosmopolitan (except perhaps the house bug, *Acanthia lectularia*), although some of the species inhabiting England are also to be met with in China and Japan.—(J. SC.)—*Encyclopædia Britannica*.

HOW TEA SOMETIMES GIVES HIGH DIVIDENDS.

High dividend paying Companies may have been formed, Phœnix-like, out of the ashes of former Companies, upon new capital, altogether out of proportion to the actual cost of the properties? Yet such is the fact as regards more than one of the best paying concerns. When the crash came in 1869 gardens which had had R14 to 15,00,000 spent upon them sold for R40,000 for 1,400 acres in area. What garden could be made at a cost, as here seen, of a little over R28½ per acre! Then again, I was once told of a garden which had cost a large sum to make, being sold for R 5,000; yet in the first year after the sale, its seed alone was sold for R 30,000 to the Assam Company, who had also to clear the jungle from the tea and cart away the seed. Again another instance: I once heard of a garden whose teas now fetch excellent prices here, which garden I was told cost to the original proprietors R30,00,000, and was sold in the crash for R15,000. These figures I lately discovered in a note-book many years old, and they called to mind the well-informed planter who gave them to me on board of a river steamer. I cannot vouch for their absolute correctness, but there were many instances in those days showing terribly wide margins between cost-price and the sale-price obtained during the panic; and yet it is upon these ridiculously low capitals (with perhaps additions for working expenses and extensions, from time to time), that large dividends are for the most part now declared. If proprietors after this 'get rid of their unjust comparisons in estimating the worth of their managers, my object will have been served, and trifling inaccuracies in the above figures, should there be any, should not affect the real issue of the question, *viz.*, that Companies paying big dividends today are, as a rule, Companies with capitals far below the first cost of the properties. I remember yet another case where the then manager purchased the estate from the Company owning it, at the time of the panic, and he realised more by the sale of the Tea-lead he found stored in the godowns, than the total sum he had paid the proprietory Company for the whole property! Doubtless that garden pays a good dividend, even in these days.—PERIPATETIC PLANTER.—*Indian Planters' Gazette*.

SHORT WEIGHTS IN COCOA.

At the usual auctions on Tuesday last, 17th December, Mr. Albert Lehmkühl, cocoa broker, took the opportunity of calling the attention of the trade to the numerous instances of deficiencies in the weights of cocoa which had come under his notice this year. He did so for the purpose of finding out whether means could not be adopted for remedying the evil, and also wished to know if his friends, the manufacturers for whom he buys, were in any worse position in the matter than their neighbours. Mr. Lehmkühl, in his remarks, alluded chiefly to Trinidad and Grenada as being the descriptions of cocoa showing the greatest discrepancies between the landing and the actual delivery weights; and after making careful inquiries in various quarters, he had come to the conclusion that if the shortness of weight did not occur in a natural way—that is, by the cocoa becoming drier while it was stored in the bonded warehouse—the increased lightness of the bags by

from five to ten pounds per bag or more must have been caused afterwards by pilfering or other irregular practices. The dock companies had been written to on the subject, and could not satisfactorily account for the differences in the weights, and some persons seemed inclined to throw the blame for the deficiency upon the too frequent samplings of the article that are allowed before it is finally sold for consumption, as well as upon the largeness of the samples that are drawn each time, the payment for which goes only into the pockets of the dock or wharf companies, without a fraction of the money being handed over to either the importer or the purchaser. In the discussion which followed, it was suggested that the amounts abstracted from the bags, when sampled, should be endorsed upon the back of the warrants, so as to be deducted from the landing weights when the cocoa is delivered, but the impracticability of this plan being tried was at once seen when it was mentioned that the warrants might happen to be in the safe custody of a third party, humourously described as being "uncle" to all those people who are at times in want of a little help. One of the largest manufacturers of cocoa, who was present, said that he quite agreed with what had been urged by Mr. Lehmkühl, and while admitting that the loss in weight had been occasioned by the same cocoa being sampled too often, and other causes, he stated it as his opinion that the spring and summer having been unusually dry, and the cocoa being also in a similar state when shipped from the West Indies, a greater degree of shrinkage in weight had been going on than they had been accustomed to find. This manufacturer also informed his hearers that he had to complain of a heavier loss in the weights of the finer qualities of cocoa than in the commoner sorts, which rendered the case still more serious to the buyers, who not only lost their money through having a smaller bulk forwarded to them, but were also losers in giving higher prices for a quantity which the bags did not contain. Thus the trade expressed their views on this important question, but without coming to any definite resolution; and although the idea of introducing "re-weights" was mooted, its consideration was adjourned *sine die*.—*Indian Planters' Gazette.*

A VISIT TO THE CEYLON COCOA (CHOCOLATE) DISTRICTS.

The specimens of cocoa trees in the Botanical Gardens at Peradeniya were pronounced as very poor. They were upwards of 25 years old. It was not their age, but the close planting that seemed to interfere with their proper development. The shade, too, seemed too much for a tropical plant needing a certain amount of sun warmth. Next morning we drove northward of Kandy, and after crossing a massive bridge spanning the Mavellignnge, took an easterly direction towards a lower range of hills. The road (well metalled) for four miles or more bordered the river. Strips of land between the road and the river were planted with coffee owned by natives. Save a few trees recently planted, there is no sign of cocoa cultivation making rapid progress to supplant coffee in these small holdings. After ascending about 500 ft. in 2 miles, we reached a veritable coffee estate well kept up and in bearing. The coolies were busy picking the red cherries, and we had no idea that we were to stop here to examine the place as a cocoa plantation too! The cocoa (chocolate) was young, and was planted at about 12 ft. apart amongst the coffee. The coffee bushes were lopped and kept down at 4 ft., and the cocoa averaged 7 or 8 ft. high. The trees looked delicate, and it was surprising to see how they carried on their slender outer branches their large fruit. Some of the trees had as many as eighty fruits and almost all matured. The soil in the neighbourhood was chiefly of a soft rich darkened loam; but higher up the hills and near the ridges it was very poor, and consisted mostly of gravel of excellent quality for road-making and nothing more. The cocoa trees in the ravines and sheltered nooks were healthy and strong. In exposed places the wind is said to stunt their growth, but the poorness of the soil in such places is the more probable reason. The cocoa trees must be put down in the category of orchard fruit trees. They will no more succeed on the hill tracts in Ceylon, as fields of coffee and tea do in continuous open sheets, than would the mango and other fruit trees. The natives in the valleys and at the foot of the hills have the best land for its cultivation, and though these plots are small, the yield from them is likely to be very large. Owing to the accumulation of rubbish, cattle manure, &c., for centuries, the soils of these gardens are rich. The native coffee, unpruned and untended in these gardens, was said to yield as much as a ton of coffee per acre, and valued, in good times, at R1,000 or more! Half that yield was an average crop. The cocoa cultivation commenced vigorously amongst the planters about four years ago, but very little progress has been made by the natives as yet and unless some practical scheme is caried out by the Government, it is not likely to be of much benefit to the natives, and ultimately to the Government. Instead of throwing extra burdens, taxations, &c., on the European planting community to make up deficiency of revenue from native sources needed to maintain Government, it would be better policy to endeavour to place the natives on their former financial footing by encouraging the cultivation of new products amongst them. At present it is a disgrace to the Government to see scores of tax defaulters being fed in jails at the Colony's expense. Taking a short route through a tract of low undulating land and crossing several streams, we reached another cocoa plantation. It was once a sugar estate, then a coffee, and now a flourishing cocoa estate! The soil here was darker than the last place we visited, and showed signs of limestone. As it was almost all level there was no wash or waste of soil here. We were lucky in meeting a party of pickers gathering the fruit. They had to be closely watched by an assistant overseer to prevent careless picking. It is not an easy matter to detect a properly ripe cocoa pod from a green or a matured one. Some of the pickers used a light short hollow stick, about a foot in length and the thickness of a finger, to detect the condition of the fruit. When rapping a fruit a sound is emitted, a dull heavy "thud" indicating immaturity, and a slightly hollow sound a sufficiently ripe pod. Some of the intelligent pickers could tell a ripe fruit by sight. The pods are removed to a barbacue where they are cut open and the seeds or nibs gathered. The seeds are covered with a white pulp very pleasant to the taste, and it is this that attracts one class of enemies, such as bats, squirrels and rats during the cocoa season. The seeds are heaped and covered over with coarse mats and left to ferment. This is done to remove the pulp easily, as well as to destroy the germ in the nuts at an early stage. If the germ were allowed to exist or start for a few hours, the nibs or nuts do not keep well, and rot before they reach a foreign market. Save a little care in the picking and fermenting and drying of the seed, the management of a cocoa plantation is neither an expensive nor a difficult matter. While for a tea estate it is calculated that the labor staff usually employed on a coffee estate will have to be trebled, a cocoa plantation, well planted up and over three years old, will need only half the number of hands employed on a coffee estate. From the opinion and sayings of one gentleman with five years' experience, we are inclined to believe that the profits will not be more than what could be got from an average tea estate, very probably less. By high cultivation, as manuring, proper shading, irrigation, &c., our informant calculated that from the third to tenth year an average return of R150 per acre could be depended on, and R200 per acre from the tenth year. We paid a visit to the store to see the process of drying the nibs. On a good warm and yet breezy day it was quickly done. Square shallow bamboo baskets with moveable tops were used. The baskets were placed in the open air exposed to the sun with the tops on. The seeds were placed below in thin layers. In dry weather this plan succeeded, but in wet weather all kinds of "firing" have been tried with far from satisfactory results. The recent introduction of new patent fruit driers will tend to better results, judging from a few trials already made in Colombo.

A good deal appeared in the local journals about the evil effects of the *Helopeltis antonii* on cocoa, but we saw very few trees severely injured, and met no cocoa planter who looked upon the pest as a great unconquerable foe, blasting this new enterprise. Tea is certainly making rapid strides, but our friend shrewdly suspects that proprietors of cocoa plantations will in the end be best off, not having to depend much on skilled supervision, expensive machinery,

and a good and large labor staff. To a small capitalist who means to be his own "manager" a cocoa plantation holds out greater temptations than a tea estate, and if suitable land is secured, we see nothing to doubt the investment being a safe, besides a long lasting one.

Of dry nibs for export we saw scarcely a ton of it in Kandy. A few heaps in the coffee boutiques, gathered indifferently from native trees, was all we saw. In a place said to have held in a day coffee worth R500,000, when coffee was king, there was only a cwt. to be had! There is no cocoa locally prepared for consumption. One planter tried it, but as the natives did not appreciate the drink, the manufacture was given up.—*Indian Planters' Gazette.*

THE CACAO-BUG OF CEYLON.

The note by Mr. Distant in your number for October 30 (p. 684)* may perhaps lead its readers to think that the insect which has lately been the subject of a report to the Ceylon Government has been wrongly identified by me as *Helopeltis antonii*, Sign. As that report will, however, before this have reached England, the matter will probably have been set right. I am not an entomologist, nor have I here the opportunity of referring to Signoret's original description or to other descriptive works; but the insect is, without any doubt at all, that which is well known—too well known—in Assam and in Java as *Helopeltis*. In the former country it is the destructive tea-bug or "mosquito-blight,"† and in the latter it is the notorious pest of the cinchona plantations.

As to the fragments which reached Mr. Distant, they were apparently insufficient for identification, further than with the family *Reduviidæ*. The cacao-tree harbours a host of Hemiptera, and planters are very apt to confound the innocent with the guilty. Its only formidable enemy in this order of insects, however, so far as I have seen, is the *Helopeltis*.—HENRY TRIMEN, Royal Botanic Garden, Peradeniya, Ceylon.—*Nature.*

RUBBER AND ITS USES.

COMMON wooden trunks are rendered waterproof by being covered with gum-elastic materials.

RUBBER ivory and whalebone are particularly suitable for water or spirit levels, on account of their solidity and their not being liable to warp or crack.

LEVELLING rods when moulded of rubber may be made hollow and light and without a tendency to warp or spring as when made of wood. Like scales and rules, they are graduated in moulds when vulcanised.

SUPERIOR dressing boxes may be cheaply manufactured of rubber ivory instead of fine wood, and when desired can be made with a soft surface of artificial gum-elastic upon the ivory to make them resemble such as have been commonly covered with morocco.

BATHING and flesh gloves are made of knit goods or elastic compound with a sheet of elastic tufted sponge cemented to the face of the glove. They answer the ordinary purposes of a flesh brush, and are made superior to bristle brushes for bathing, as they are not softened by being saturated with water.

GUM-ELASTIC vellum and tissue are cheap and durable materials for the manufacture of banners and flags, not being liable to damage from wet. Fringes and tassels for them may be made of gum-elastic cord spun and twisted while the gum is soft, with the same facility as common thread.

RUBBER ivory has long been recognised as well adapted to the manufacture of the cases of musical boxes, because of its elasticity and durable properties, and the facility with which it is moulded and ornamented.

EXPANSIVE cork is made of gum-elastic compound with a screw of metal or rubber whalebone passing through it. Turning the screw compresses or enlarges the cork and makes it fast. Reversing the screw allows it to be drawn. —*Indiarubber and Guttapercha Journal.*

* See *T. A.*, p. 517.—ED.

† Since my report was written, Mr. Wood-Mason's short treatise on the tea-bug has reached us here.

THE JAPANESE NATIVE TEA DEALERS.

The *Meiji Nippo* publishes a curious compact which has been agreed upon by all the influential native tea dealers of Yokohama. Some of the foreign firms of the port, so it is alleged, have hitherto made a practice of declaring, that the tea they receive is inferior to the sample, and of beating down the price of the dealers on this pretext. One firm, the name of which we do not publish, appears to have specially excited the indignation of the dealers, who have agreed upon the following covenant:—"The firm at No. — invariably make, on some pretext, and in an oppressive manner, a reduction of 5 per cent in the price of tea delivered to them. This is done even when the goods do not in the least differ from the sample, the reduction for dust being as much as 2 per cent. In addition to this, the tea when weighed by them undergoes a great decrease in weight. It is beyond doubt that transactions with a firm of such vicious principles involve us in great loss. Such being the case, we hereby agree to suspend business with the firm in question, in testimony of which we sign and seal our names below. Should the firm give up the practice, this agreement will be annulled." We cannot tell how much or how little truth there may be in this report, but if the offending firm is really guilty of such practices, the remedy adopted by the Japanese is proper, and will, doubtless, prove effectual. The strange part of the business is, that any covenant should be necessary. Elsewhere, a firm comporting itself in the manner described, would lose its business without any recourse to pacts or combinations on the part of its customers. But the peculiar ideas educated by the guilds of anti-Restoration days evidently survive still in the breasts of Japanese merchants. Either the relations between the local foreign buyer, and the Japanese seller must be placed on a different footing, or the former's functions will gradually disappear. Under the present system the inducements of the producer and the preparer to be honest and painstaking are of the remotest possible description, and the staple is heavily taxed by the necessity of undergoing at the open ports, processes which ought to be performed, at half the cost and with twice the advantage, at the place of production. It is all verywell to say, "leave the Japanese to discover the cost of direct trade for themselves. Bitter experience will force them back to the old grooves." So long, however, as commerce in the two principal staples is encumbered by conditions which offer a premium for emancipation from foreign agency at the open ports, so long, we may be sure, will the present impulse continue to be effective, and so long, also, will there be encouraged among the Japanese that spirit of injurious combination, an example of which has suggested the above remarks.—*Japan Weekly Mail.*

RUBBER NOTES FROM THE REPORTS OF BRITISH CONSULS.

RIO DE JANEIRO.—According to Mr. Consul Ricket's report on the trade and commerce of Rio de Janeiro for the year 1882, a large trade was carried on in Indiarubber, the average export of which from all the ports of Brazil, for the five years 1877-78 to 1881-82 was valued at 11,885,640 milreis. The value of the Indiarubber exported to Great Britain increased from £879,409 sterling, in 1878, to £1,460,219 sterling, in 1882, and in the latter year the total exports of all kinds to Great Britain were computed at £6,945,713 sterling, so that it will be seen that rubber is an important article of export.

PARA.—Para rubber has attained a high reputation for quality and utility, and it is interesting to note that, according to the latest Consular report (for the years 1879-82) on the trade and commerce of the province in Brazil from which it takes its name—by Mr. Consul Green—the production has continued to increase. The quantity, which amounted to 4,794 tons in 1870, rose to 6,747 tons in 1875, to 8,575 tons in 1880, 8,936 tons in 1881, and 9,624 tons in 1882. Consequently, the increase in twelve years has been 4,830 tons, and in value 19,528,000$000, or about £1,749,011 13s. 4d. Indiarubber is the chief article of export, and owing to the high prices which it commands in the principal consuming markets, it has been the means of a great impulse being given to the trade of the province. The immigration of the Cearenses has been very

beneficial, some 40,000 of them being very largely employed on the Amazon and its affluents in the collection of India-rubber. The Consul observes:—"Should the demand continue for the article, I see no reason why the yields should not go on increasing, as there are new fields being continually opened. From Peru now comes a class of rubber called 'Caucho,' in slabs or sheets of about four inches thick and two to three feet long. It ranks a little higher in value than the coarse quality, *i.e.*, Sernamby; and I should estimate that 400 to 500 tons of this quality come to market every year." Out of a total export of 9,624 tons of Para rubber in 1882, England took 3,514 tons, the United States 6,000 tons, and France 110 tons.

Ecuador.—The following figures, taken from the report of Mr. Consul Chambers on the trade and commerce of Ecuador through the port of Guayaquil during 1882, show the exports of Indiarubber for a period of six years. These reached 7,059 quintals in 1877; 6,561 quintals in 1878; 5,794 quintals in 1879; 7,995 quintals in 1880; 8,715 quintals in 1881; and 9,034 quintals in 1882. The foregoing figures show a steady increase, and it is interesting to note that during the two latter years the value of the product per quintal was considerably enhanced. The export price in 1881 was 160s. per quintal, the value of the 8,715 quintals exported being £69,720. In 1882 the price entered was 180s. per quintal, and the quantity exported—9,034 quintals—was valued at £81,306.

Guatemala.—In Mr. Consul Bennett's report on the trade, commerce, and navigation of Guatemala for the year 1883, the export of Indiarubber from San José, Champerico and Izabal is stated to have amounted to 3,454 quintals 14 lb., valued at 224,519 dollars 10 cents, the price entered being 65 cents per lb. The export is within a few pounds of the amount exported in 1882. The vexed question of tapping the trees or cutting them down is still undecided. Those in favour of cutting down allege that the quantity of rubber extracted by so doing is only equal to what would be collected in five or six tappings, after which the tree would die, and consequently that, the yield being immediate and of equal quantity with what would be given by a series of yearly tappings, and the tree in both cases dying, it is more to the interest of all to cut the tree down at once. This course, however, is forbidden by a Government decree. It is possible that the law may be rescinded, and the practice allowed on condition of two new rubber trees being planted for every one cut down.

Nicaragua.—The following table, showing the quantities and values of exports of Indiarubber from Nicaragua in 1881 and 1882, is extracted from a report by Mr. Consul Jessel:—

From.	1881.			1882.		
	Quantity.	Value.		Quantity.	Value.	
	lb.	dol.	c.	lb.	dol.	c.
England... ...	345,634	155,535	30	266·374	119,868	30
United States	1,167,896	525,553	20	1,148,535	516,840	75
Germany... ...	—	—		2,150	967	50
France	—	—		964	433	80
	1,513,530	681,088	50	1,418,023	638,110	35

The values in the above table are calculated at 45 dollars per 100 lb. in Nicaragua. The falling-off of the rubber exportation is here, as in most rubber-producing countries, the result of wholesale destruction of trees by the gatherers. All the country in the immediate neighbourhood of the river San Juan is already nearly cleared of rubber trees, and they have now to be sought for in the depths of the primeval forests, rendering the task more and more difficult.

Sumatra.—The exports of Indiarubber from Olehleh (Sumatra) during 1882 reached 1,710 lb. English, and according to Mr. Consul Kennedy's report dated Feb. 9th, 1883, "they were chiefly from the north and west coasts, and it is evident that the high prices for this article prevailing in Europe have somewhat stimulated the search for it in Sumatra." Guttapercha (a product which takes its name from this island, Sumatra being known to the Malays as 'Pulo Percha') is obtained on the west and east coasts, and in 1883 a more recent report states that it was exported to the total amount of 380 piculs.—*Indiarubber and Guttapercha Journal,*

RAW INDIARUBBER: ITS COLLECTION AND PREPARATION.

No. I.—Para.

BY THOMAS T. P. BRUCE WARREN.

A few years ago I was engaged as an electrician in laying a submarine telegraph cable between Pernambuco and Para. After the cable was laid I was stationed at Para for a few weeks, during which time I availed myself of every opportunity for seeing what was to be seen, so long as it did not interfere with my duties or inclination to be idle. It is no use disguising the fact that at midday within a few miles of the equator even an active Englishman is likely to seek the cool retreat of a hammock, in preference to any form of outdoor amusement. Bates, in his "Voyage on the Amazons," says that the Brazilians have a proverb that only Englishmen and dogs are to be found in the streets in the day, so that, at any rate in the eye of a Brazilian, it is no great sin to shirk one's work a little.

During our stay at Para we formed the acquaintance of many Brazilians, Americans, and Englishmen, so that at no time had we any reason for being particularly dull or feel our time hanging heavily on our hands. To Captain Bloem, a gentleman in the service of the Amazon Steam Navigation Company, we were particularly indebted for several interesting little trips into the forests. In these excursions Captain Talisman, a gentleman belonging to the same Company, and formerly of the Brazilian navy, acted as pilot. This same gentleman accompanied Professor Agassiz in his journey through Brazil, and was consequently well able to point out and explain to us the marvels around us. I have frequently thought that the immensity and grandeur of these forests would tempt almost any weak-minded man to go off into poetry. We were bent on sterner things, amongst them being monkey-shooting, botanizing, and curiosity-hunting. A strange sensation creeps over one when quietly walking along in these forests; snakes of the most formidable kind may be lurking about ready to pounce upon one, whilst ants, mosquitos, and other small insects are not very particular, if you interfere with them, of illustrating in a practical way their objection to being studied. Then, too, one perspires so freely that one's garments become so saturated as to make locomotion uncomfortable. After two or three visits to the forests one appears to get hardened against strange and poetical fancies.

I have met with no description of these forests which adequately represents a picture of what they really are. The vegetation is no doubt superlatively wild; the mingled chorus of the birds and monkeys, although in striking harmony with the vegetation, would lead you to believe that you were near the Antipodes to paradise. The crowded state of the vegetation keeps the trees pretty much on a par as regards girth; the wrangling for survival is probably kept under by the richness of the soil. I had no opportunity of seeing Indiarubber trees in their native wildness. These trees are valuable on an estate, and the ground is kept cleared for some distance from the butt; this gives them a chance of developing into good-sized trees. I am not aware of any account being published of the amount of rubber produced by these trees under different ages; this fact, however, is certain, that the owners of these trees will not tap them until they have attained a good size, which will of course depend on the facilities given for their development. An owner has no interest in weakening his plants by drawing too freely at one time. The incisions, instead of being carried around the tree, are more frequently made at intervals on the stem, one above the other, in a zigzag fashion. Little cups made of clay, and dried in the sun, are cemented to the tree with a little soft clay, directly under one of these incisions, so that the sap flows freely into them.

I have frequently noticed the exaggerated ideas which are evidently current with regard to the collecting of the sap. Only a short time ago I saw an illustration in which the sap is represented as gushing out in a perfect torrent. At different periods of the year the sap has different degrees of inspissation, flowing more copiously when the elaboration of sap is most active, and becoming slower as evaporation from the plant and dryness of the season set in. These conditions would indicate the necessity for

repose, and growers who have an interest in their plants act accordingly. It must not, however, be supposed that to tap a tree at this time involves any serious peril, for the sap flows very slowly, and in a day or so heals up. When sufficient sap or juice is collected it is poured into a large earthenware pan, and the liquid is dried in successive layers on a mould formed of clay, until the desired thickness is obtained, or until the juice is all used up.

The mould is thus made:—A piece of wood of a convenient length for a handle, about one inch or more in diameter, is coated with a layer of clay about 6 or 8 inches long, and from 3 to 5 inches diameter tapering at top and bottom. After drying in the sun it is ready for use. The clay-covered part of the handle is dipped into the juice and moved about so as to facilitate the removal of adherent air-bubbles, and then lifted out, and the handle carefully turned round and round, so as to keep an even thickness or coating all round. When this coating is set, another dip is made the additional coating dried, and the operation repeated for as many coatings as may be necessary. When finished the whole is held over a fire made by burning the nuts of the Urucari palm fruit until it becomes of a dark rich brown colour. In this state it rapidly darkens. It is becoming more and more rare to find this smoked Para rubber; this may be due to the scarcity of the palm nuts and the want of a suitable substitute.

Whatever may be exhalations from the roasting nuts it is evident that the Para rubber so treated may be kept for years without deteriorating. At one time, each coating was dried or coagulated by the heat from these fires. The statements made by some writers on this smoking process are absolutely ludicrous, and suggest the acceptance second-hand of a description which has been borrowed from a writer who has embellished a description by some one else, and which was probably correct until it received the adornment. The peculiar cooked-like odour of the Para rubber is due to the oil which rises from the burning nuts, and the curious shaped nuts sometimes found in packages of Para or Negrohead rubber are those which are used in this smoking.

It may be a troublesome thing to prepare Indiarubber in a climate like India, so as to ship it in a condition likely to compete favourably with the rubbers from Brazil and elsewhere, and I would therefore suggest that it may be worth while to try the effect of smoking the prepared masses of Indiarubber directly they are finished. At any rate, the danger from handling might be avoided, as Indiarubber in contact with perspiration soon becomes soft and sticky. After the bottle is finished it is cut open by a longitudinal slit, so as to remove the mould; the clay is broken up, and the handle drawn through the neck of the bottle. It is then placed under pressure, when it takes the form of the well-known Para bottle-rubber. It is a very common thing to find a small hole through the flattened bottles. These holes are made so as to string them together in piles, in which form they are sent by the collectors to Para or to the merchants.

Bates says that the thongs used in threading up the bottle is an air root of an epiphytous plant. On our visits to the forests just outside Para we saw an immense number of these thong-like roots hanging down from the highest branches of the tallest trees, and reaching to the ground. One of our party hung on to one of them without its breaking. I do not remember seeing any of these thongs in a package of Indiarubber. The strength of these thongs must be very great, as one about a quarter of an inch in diameter is quite sufficient to support about one hundred and fifty pounds of rubber.

The rubber thus prepared is conveyed by canoes to the ports from which it is exported. The merchants who ship the article obtain it from the natives in exchange or barter for other commodities. The rubber accumulates in the warehouses of these merchants until sufficient is collected to make a consignment to a shipper or broker, whence it finds its way in this country to the ports of Liverpool and London. This rubber is eagerly sought after by the Americans, and there is no doubt that its price is kept up by competition between the English and American markets. A great deal of rubber is now shipped direct from Maranham which was formerly sent to Para. The purity of this rubber commands for it a good price.—*India-rubber and Guttapercha Journal.*

ROOTS.*

In treating of the roots of plants this evening, I may request you to dismiss from your minds any expectations or apprehensions of marvellous descriptions of tropical or rare roots on the one hand, or of a list of the peculiarities of various kinds of roots or so-called roots on the other, though it is not improbable that some of the facts will be, in part at least, new to some of you, as they certainly are to many people. I do not propose even to put any new discoveries before you. It has seemed much more to the purpose to show, as well as time will permit, that a vast amount of interesting and important information can be derived from a proper and systematic study of the roots of a common plant—information, moreover, which is important alike to the scientific botanist and to the practical agriculturist, two people who find they have more and more in common each day they come to know one another better. As the diagrams must in part have told you already, I propose that we meet on ground familiar, to a certain extent, to every one; and the sequel will show, I hope, that we have in no way acted unwisely in taking each other into confidence on the subject of an ordinary root, such as is well-known to all of us. So much is this the case, that our study may be confined for the most part to the root of the common broad bean and a few other plants of our gardens.

[The lecturer then shortly described the germination of the common bean, maize, and a few other plants, and illustrated by diagrams the mode in which the first or primary root of the bean seedling emerges below, as the young seedling shoot (or "plumule") prepares to force its way upwards to the light and air. Next followed a short consideration of what this root may be said to be.] Anticipating matters to a certain extent, it may be shortly described as an organ for fixing the rest of the plant to the substratum or soil from which it absorbs certain food materials. By confining our attention to this typical and well-known form of root, we may avoid any complexities resulting from the consideration of the more extraordinary cases occurring among the lower plants, or among curious aërial epiphytes, parasitic or otherwise, and other abnormal forms—forms which would demand several lectures by themselves.

The roots we have to consider, then, are organs for anchoring the rest of the plant firmly into the soil, and for absorbing certain matter dissolved in water from that soil. Obviously, we may do well to see, first, how the root gets into the soil; and secondly, how it accomplishes its objects when there.

When the young root first peeps forth from between the coats of the seed, it is seen to have its tip directed downwards towards the centre of the earth. Now this is not an accident; for if the seed be turned over, so that the apex of the root is made to turn upwards, its tip soon bends over, and again becomes directed downwards. [Mr. Ward then proceeded to explain, as shortly as could be done without detailed experimental evidence, that this persistent turning earthwards of the young root is due to a peculiar property, almost of the nature of a sensitiveness or perception to the influence of gravitation, and is not due merely to the weight of the organ.]

Next, evidence has been obtained to show that the tip of the root has a slightly rocking or swinging movement, which is more or less of the nature of the movements so well-known in the case of the stems of twining plants; the tip of the root, in fact, not only moves earthwards, but tends to describe a very steep spiral as it does so. These successive very slight noddings to all sides of the tip as it proceeds in a line directed towards the centre of the earth are extremely slight, it must be borne in mind, but they may aid the point of the root to wriggle its way between the particles of earth in a loose soil, or to run down any crevice or hole it meets with.

Thirdly, in addition to its determined tendency to descend, though in a very slightly spiral course, the tip of such a root as we are describing has been found to be

* Abstract of a lecture delivered before the Manchester Horticultural Society, in the old Town Hall, Manchester, on November 6, by H. Marshall Ward, M. A. Fellow of Christ's College, Cambridge, and Assistant Lecturer in Botany at the Owens College.

peculiarly sensitive to the contact of solid bodies. This extremely curious phenomenon could only be fully described by references to experiments and matters which we have scant time for. It must suffice, therefore, to state that there is evidence to show that the *extreme tip* of the root, on coming in contact with a hard resistant body, is caused to turn aside *from* that body, and if it comes simultaneously into contact with two bodies, one of which is harder than the other, it is caused to bend away from the harder of the two. This property is all the more curious because, at a portion of the root a very short distance behind the tip, contact with a solid body causes that part of the root to curve over the touching body, much in the way that my finger is now curved over this wooden pointer. As already stated, time will not admit of our examining these very matters more closely—they form subjects for lectures in themselves.

But we have not yet finished our survey of what these sensitive tips of the roots are capable of. Experiments show that they turn towards a wet surface or atmosphere—a fact of great importance, and one which no doubt lies at the base of the explanation of the choking up of drain-pipes, &c., by the roots of neighbouring trees. Further, the apex of the root of such a plant as the bean we are considering avoids the light—avoids it as energetically as the leaves and green part turn towards it. The two facts thus tersely put, viz., that the tip of the root tends towards a damp spot and avoids an illuminated one, are of course also in agreement with the rest of the behaviour of our germinating bean, and hence the root descends into the damp, moist granular soil.

It is now time to see what sort of structure this wonderful root-tip possesses, and to inquire whence comes the impulse which drives it forwards into the soil—for it will be seen that while the forces producing the various curvatures which have been referred to tend to guide the apex of the root downwards between the particles of soil, towards the darker, moister, deeper parts, they cannot be expected to drive it into the soil.

In the first place, the tip is a firm, conical, smooth body, covered with a slippery, loose root-cap, as seen in the diagrams. Now, it cannot be too carefully borne in mind that the true tip of the root, beneath the covering cap, is resistant and somewhat elastic; it consists of multitudes of minute tightly-packed cells, each densely filled with protoplasmic substance containing very little water, and of a consistency resembling in some degree that of a well-made, hard-set jelly. Perhaps, indeed, a better idea of it may be gained if the conical tip of the root is compared to a firm, resistant jelly, cut up by delicate partitions into multitudes of minute blocks, which, however, are not separated from one another at all. In any case, it is clear that such a cone, if steadily and slowly driven by a persistant force from behind, is admirably adapted for penetrating between the particles of soil, especially if we bear in mind the following facts: (1) the cone is protected by a slippery cap of loose cells, which prevents the abrasions of the particles of soil from injuring the cells beneath; (2) the driving force is steady and continuous, and directed vertically, *i.e.* along the axis of the cone; (3) the tip oscillates slightly from side to side, and is thus probably (though not to any very great extent) insinuated between the earthy particles, no doubt being aided to a certain extent by other properties to which allusion has been made. It is of course obvious that the last thing we should expect of such a cone is that it could take up quantities of water from the soil: its structure is clearly in no way adapted for such a purpose, if only from the fact that there would be nowhere for the water to effect an entrance.

And now comes the question, What is this steady-continuous driving force from behind? Well it is due to, the simultaneous elongation of the hundreds of thousands of little cells situated a short distance behind the more rigid cone we have just examined. No doubt it seems a hard fact to grasp—that the absorption of water, and the intercalation of minute particles of substance in the interior of the cells shown in this diagram should be capable of steadily driving the apex of the root into the soil; but it is a fact nevertheless. Perhaps you will apprehend the matter more clearly if I offer you a well-known illustration which, it is true, does not exactly cover all the facts, but when will, at any rate, aid you in overcoming some initial difficulties. You are well aware that a wedge of wooden driven firmly into a crack in a rock and then moistened, swells, and that it may swell so powerfully as to facture the rock; very well, the elongation of the cells behind, which steadily drives the firm cone of the root forwards, is to a great extent due to the absorption of water, which causes each cell to grow longer. I say to a great extent' because, while the water is, on the one hand, absorbed in a slightly different way and enlarges the volume of each cell to a much greater extent, there are on the other hand, forces at work which cause new particles of substance to be added to those originally composing the cells, and so fix the cells, as it were, in their condition of greater elongation, strengthening them at the same time. But this is not all. Besides growing longer, and thus driving the apex steadily forwards, the cells behind increase in diameter, and so push aside the particles of the soil with a force which would astonish you if I entered into figures; this, however, can only be adverted to here, since we must now pass to the explanation of one or two other points.

It is clear that, great as the driving force supplied by so many elongating cells—and, of course, it is upon the simultaneous action of countless thousands of cells that the driving power depends—it would soon cease to be of much use unless a holdfast were insured at some point behind. This brings me to the consideration of an extremely important matter, and one on which I hope to make you quite clear. At first, while the root is still very young (as in this diagram), the weight of the seed above, with that of any soil covering it, seems to suffice to afford the necessary points of application; and this will doubtless be supplemented immediately afterwards by the increase in diameter of the upper part of the root.

When the root has attained some little length, however, a striking change takes place in its behaviour to the surrounding soil. First, let me call your attention to the following points, as illustrated by these diagrams. When the young primary root has attained a length of about four to six or eight inches—depending on circumstances which we need not occupy time in examining—the older portion nearest the seed has ceased to grow in length, and its surface is becoming clothed with a dense covering of very delicate hairs, which will be referred to in future as the "root-hairs." Each root-hair is an extremely slender sac—a sort of long tubular bladder, in fact—which possesses in virtue of its peculiar organisation an extraordinary aptitude for taking up water, and for attaching itself to the particles of soil which it comes in contact. These facts are well illustrated by reference to these diagrams, to which I wish your attention for a few minutes.

From the delicacy of these root-hairs, and from their springing at right angles from the surface of this part of the root, radiating in all directions between the particles of soil, to which they immediately proceeded to glue themselves, it is obvious that they are saved from being torn away as the tip of the root is slowly driven forwards between the particles of soil; if they were to arise on the tip itself, or on the parts which are elongating behind it, they would infallibly be removed by the abrasion or the particles of soil. Instead of this, however, they become developed on the parts behind in successive multitudes as those parts cease to elongate.

At the same time, the thousands of points of attachment established by the root-hairs afford the holdfast which becomes more and more necessary as the apex of the root is driven further and further forwards, and as the weight of the aërial parts of the plant, with their increasing surfaces exposed to wind and weather become larger.

Meanwhile, leaving aside for the moment the consideration of how these millions of root-hairs take up the water and food-matters from the soil, the young root has been making preparations for obtaining a still firmer and wider holdfast on the soil, which will, at the same time, enable them to absorb water and food-materials at millions of new points further and further removed from the centre at which the primary root commenced its operations. To understand this, I must call your atten-

tion to this diagram, showing how the branching of the root proper is brought about. In the interior of the growing root a number of cells begin to multiply at certain points, and to form the young beginnings of lateral roots or rootlets; further back you see these young lateral roots upheaving the tissues of their parent root as minute knobs. By this time, however, these portions of the mother root have ceased to grow in length, and thus the tender little tips of the lateral roots can protrude and be pushed into the soil around without danger of being dragged off or injured, as they would inevitably be if this part of their mother root were still actively elongating. Notice carefully the exquisite adaptation to the circumstances, though brought about in a slightly different manner; no time is lost in the preparation of the young root branches within the tissues of the parent root, but the tender tips, as in the case of the root-hairs, only proceed to grow radially into the surrounding soil when the growth of the mother root in a direction across their long axes has ceased.

Time will not allow of our examining these matters more in detail; but I cannot avoid calling your attention to the fact that these lateral roots are sensitive to gravitation in a manner different from the primary root—they grow, not straight down towards the centre of the earth, but across the vertical, it may be more or less inclined, in different cases. In other respects they resemble the primary root generally, in their turn producing root-hairs and daughter roots, which radiate from them in all directions into new portions of the soil, as shown in this diagram.

I need not do more than point out to you that it would be difficult to conceive of a series of adaptations better calculated to insure that the various parts of the root-system come successively in contact with the whole mass of soil traversed; and when your eyes follow mine over this diagram, you will agree that matters have become so arranged, so to speak, between the roots and the soil, that every part of the latter is laid under contribution. Notice how this vertical cylinder of earth is first bored through by the primary root, and then traversed in all directions by the root-hairs, in a wave, as it were, passing from above downwards. Next come the lateral roots, burrowing in all directions from the main shaft, and each in turn demanding toil from the cylinder around it by means of its wave of root-hairs. Then follow tunnelings along the lengths of each of these rootlets, and on all sides at right angles to them, until every nook and cranny has been investigated by these enterprising rootlets and their prying root-hairs. Quite apart from all else, therefore, the root-system obtains a greater holdfast on the soil by driving its tips in on all sides.

But I must now draw your attention to some matters which throw even more light on our subject. The root-hairs, as they develop successively from above downwards on the primary root, or on the lateral rootlets, come into the closest contact with the particles of soil—contact so close and firm, in fact, that they cannot be torn away without injury. There are experiments to prove that their cellulose walls become actually moulded and gummed on to the solid particles of quartz, slate, and other rocks of which ordinary soils are composed, and this diagram shows how we can lift up a relatively large cylinder of soil adhering to the root-hairs of a young seedling.

Now you are probably aware that the sort of soil in which a healthy plant flourishes contains air-bubbles as well as water in the interstices between the particles, and into which the root-hairs become insinuated. Bearing this in mind, you will have no difficulty in understanding from the diagram how root-hairs absorb the aërated water necessary for their well-being. I need simply make the additional remark that each little bag-like root-hair takes up the liquid water through its permeable walls into its interior, in some respects very much as a bladder full of a solution of sugar or salt absorb water if placed in it.

But this water taken up by the root-hairs and passed on into the rootlets and so on up the stem (a process for which provisions are made which we cannot go into here), is not pure water; it contains, besides air, certain small proportions of the soluble matters found in all soils. It is, in fact, much like ordinary drinking-water from a well or spring, which always contains some matters in solution. But the roots want certain other minerals, which will not dissolve in pure water to a sufficient extent under the ordinary circumstances. Well, the root-hairs, in making use of the oxygen which they, like all other living bodies, require, give off small quantities of acids which aid the solution of these more refractory matters.

And now I have finished—not because the subject is exhausted, but because the time at our disposal is. I hope the object has been attained, and that you fully realise how well worthy of study is a common living root. Not only is it instructive as a simple object of dissection, a subject upon which I have had no time to dwell, but the peculiar properties which stamp it as a living organ themselves afford material for much thought and investigation. When we go further, however, and see how the structure and the functions depend upon one another, some very curious reflections thrust themselves upon us; and if time had allowed us to look at these matters from the other platforms of view—to see how old errors have gradually been explained away on the part of observers, and how what may be called improved adaptations have arisen in the evolution of the root as an organ—these reflections would have obtained in depth. But we have taken a glimpse at matters still more comprehensive: we have touched upon that important question of the relation of the root to its physical environment, and it is not difficult to see numerous points where the struggle must have been intense before the plastic substance of the root was enabled to meet the requirements necessary before it could become a dweller in the land. The evidence of progress and adaptation to its environment on the part of the root is, in fact, so striking and conclusive, that we might take it as a text for a sermon on evolution were such necessary. I have been strongly tempted to occupy some more time with reference to the interesting phenomena shown by roots which cling to trees and walls, &c., or which rob other plants of food-materials; and had time allowed, I would have liked to say a few words about some other adaptations, such as those by means of which roots become pulled up taut in the soil. However, these and other matters cannot be even mentioned, and, indeed, each one deserves a lecture to itself.—*Nature*.

BÊCHE-DE-MER FISHING.

BY WILFRED POWELL, F.R.G.S.

Bêche-de-mer (also called Biche-de-mer, Tripang, Trepang, Sea-cucumber, or Sea-slug, terms applied to various species of the genus Holothuria) is an article of food apparently little known to epicures in this country, although, I believe, it has of late years become a dish of much popularity amongst the wealthier classes in France; and Delle Chiaje some forty years ago said that Holothurians were eaten by the poor inhabitants of the Neapolitan coasts. It has, however, been for ages highly esteemed as one of the greatest delicacies prepared for the table of the enervated upper classes in China; indeed, even a poorer Chinaman will often go without some more necessary article in order to indulge in his favourite dish. Its appearance is certainly not calculated to give a very keen edge to the appetite, being as much like a huge slug as anything.

I propose in this article to give some account of the existing bêche-de-mer industry. Anoyne desiring to become acquainted with the leading physical characteristics of the animal, and its position in scientific classification, will find those points discussed by Mr. P. H. Carpenter in vol. vi. of Cassell's "Natural History," edited by Professor Martin Duncan, a work accessible to all. It might suffice here to say that the genus Holothuria forms with Cucumaria, Psolus, &c., an order, Pedata, included in the class Holothuroidea of the Echinodermata. We have some Holothurians on our own coasts, and about thirty-five different varieties are enumerated by Chinese traders, though only about five or six have any commercial value. An account of these is to be found in Simmonds's "Commercial Products of the Sea," by Capt. Andrew

Cheyne. Various notices of the old fisheries for bêche-de-mer are given by Flinders, Parker King, Crawfurd, and others. At the present time many vessels are fitted out and despatched from the different ports of the Australian colonies in pursuit of this industry, the numerous reefs of the Great Barrier abounding in bêche-de-mer. The number of vessels has, however, fallen off during the last fifteen or twenty years, as nearly all the reefs immediately surrounding wooded islands have been denuded of their fish, wood being a most necessary article in the curing process. It has therefore become impossible for small vessels to engage in the business, and the employment of much larger ships, of sufficient capacity to carry a considerable quantity of wood for the smoke house, is necessitated.

[Then come descriptions of the smoke house for curing the slugs and the mode of gathering them from the coral-reefs.]

As before mentioned, there are many kinds of Holothuria, but only six are collected for the Chinese market. These are known to the white man as "black fish, red fish, prickly black, prickly red, white teat fish, and black teat fish." Sometimes also a white sand fish is collected, but only if there be a scarcity of more valuable kinds. Some knowledge is required to determine the real black fish from stain fish, which, if touched, will stain the hands a bright crimson that is difficult to get off again. The only use made of this description of fish is by the natives of some of the South Sea Islands, who rub the entrance of the crevices where they suppose "squid" to be lying, which has the effect of making them come out, when they fall easily victims to the spears of the natives. It is also difficult to distinguish some of the sand fish from the marketable red fish until they are trodden on or touched, when they eject a quantity of white stringy fibres, which, coming in contact with the flesh of one's leg or hand, causes an intense itching for some little time.

Whilst searching a reef (unless one knows how to search), on its becoming dry after the tide has fallen, one might easily be led to suppose that it was not worth the trouble of working, so small a show is there of black fish, or indeed, of any kind of bêche-de-mer; but if the coral boulders are lifted, under each will be found one or more holothurians, intended or squeezed into the shape of the cavity in which they lie. Although bêche-de-mer is not soft to touch, it is wonderful into what small apertures they contrive to insert themselves. On the other hand, when the tide is returning, they emerge from their hiding places, and the reef swarms with them. Their usual mode of moving from one place to another is by contracting themselves into a tight ball and allowing the flowing tide to wash them to a fresh feeding place. Black fish, as I have already observed, prefer the live coral. They are, when full-sized, about one foot in length, and from three to four inches in diameter. This fish, when handled, empties itself of its inside—or, as the bêche-de-mer man technically puts it, in language more graphic than delicate, "spews"—which appears to be a habit common to all Holothurians.

The red fish, which is perhaps slightly less common than the black fish and which grows to considerably larger dimensions—as much as 2 ft. in length, by 10 in. to 12 in. in circumference—is coloured a rich tawny red on the upper side, prefers a coarse sandy bottom, and is of a much softer nature than the "black teat" or "sand fish," though less so than the prickly black or prickly red; these latter are much the same colour as their namesakes, but are covered on the upper side with small pointed excresences, from which they take their name.

Teat or pig fish, so called from having slight protuberances on each side, somewhat resembling the teats of a pig, are of two kinds, black and white; they are generally considered the most valuable description of fish, weighing heavier when dried than any other kind of bêche-de-mer. They are much broader, flatter, and harder than black fish, and usually found on rotten or dead coral banks. It is difficult to say whether the white teat fish is the same species as the black teat fish, or merely in a different stage of development, being found together on the same bank; indeed, it is a misnomer to call them white, as they are more often piebald, it being quite a rarity to find one entirely white. On the other hand, they may be a separate species, or even a cross between the black teat and the whitish-coloured sand fish. The latter are found generally half buried in the sand on the lee side of a reef or sand bank, and are rough and coarse, growing to about the same size as black fish. They are not considered very valuable, but help to fill up the bags, mixed with the other kinds. * * * * *

Bêche-de-mer is mostly sold to the Chinese merchants in Sydney, where it fetches from £60 to £120 per ton, according to the market and quality of the fish. Some, however, is forwarded directly to China, where no doubt it fetches a little more; but there is freight and insurance to be deducted, which brings it to about the same value in the end.

In order to convert the fish into soup, it is first plunged into scalding brine, which enables the cook to remove the black skin on the outside, leaving the white gelatine-looking flesh; this is again soaked for forty-eight hours in warm water, when the fish swells to nearly its original size; it is then cut into dice of about half an inch square, and placed in a pan with two parts of water to one of bêche-de-mer, where it is simmered until it is dissolved into a thick glutinous jelly, nearly transparent. It is then passed through a fine sieve or muslin in order to separate any particles of skin or fibre that may remain; and on being mixed with other ingredients, according to the taste of the consumer, makes the most strengthening, stimulating, and delicious soup ever prepared.—*Field.*

AMERICAN SUGAR AND COFFEE PLANTERS WANTED IN SAMOA.

BY CONSUL CANISIUS, OF APIA.

It seems a pity that these islands, whose trade we ought almost to monopolize, send us nothing but copra. Thousands of acres of fine land, which could be made to produce immense quantities of sugar, coffee, and other valuable tropical products, of which the natural market would be San Francisco, are allowed to remain idle. Experienced planters here say that the climate of these islands, as well as the soil, particularly adapts them for sugar growing. The moisture is always abundant, so that the planter would not need to stand in dread of drought. If some of our sugar or coffee merchants, with sufficient capital will establish plantations on these islands, I may safely predict that Samoa will become, in a very short time, a second Hawaii. They could adopt a plan, which works admirably in other groups, namely, that of dividing up the land into small lots, to be apportioned out among Chinese settlers, the owners to say what kind of crop is to be raised. The Chinese in return would pay over a certain portion of their produce as rent, and sell the remainder to the proprietor, purchasing their supplies at his store. This is undoubtedly the most practical plan, besides a larger amount of produce would be raised if the laborers were directly interested in the crop. Thus would these islands yield large quantities of one of the most marketable productions of the tropics, and we would obtain as great a control over them both commercial and political, as we now have over King Kalakua's dominions. When the Panama canal is opened, which event M. de Lesseps fixes for 1888, the importance of the Samoa group will increase vastly to all nations having trade with Australasia, and especially to the United States. Pagopago, the finest natural harbor in the South Seas (and where the United States naval station is situated), lies almost in the direct line of that great stream of commerce which will some day find its way through the Isthmus of Darien, from our Atlantic sea coast and Europe to Australasia. Even now the Pacific mail steamers, plying between San Francisco and Auckland, pass within a few miles of this harbor, and when the increased trade which would spring up with the establishment of American plantations in the group makes it profitable enough, will no doubt call there, as they now do at Honolulu. The Fiji group will also benefit by the opening of the Panama canal, but never to such extent as to Samoa, for vessels cannot venture amongst its dangerous rocks, reefs, shoals, and intricate passages without considerable risk, especially as Fiji is directly in the "hurricane track," which is not the case with the

Samoan group. Besides, in this latter group there are no outlying dangers, every reef and rock is close to the shore of the larger islands, and the few dangers which do exist are plainly visible to the mariner. Therefore, let our merchants see what they can do to secure commercial control over the group before it is too late. What is most needed is the establishment by Americans of sugar or coffee plantations here, for Samoa is an exclusively agricultural country, and these two articles, in such great demand in the United States, are certain to become her great staples. American planters and American merchants must march together, the planter in the van, with the merchant backing him closely up. This is the only way I can devise of increasing our trade with the islands, which at present produce little or nothing which finds a good, steady sale in our markets.—*Indian Mercury.*

JAPANESE VEGETABLE FOOD PRODUCTS.

The Japanese Commission at the late International Health Exhibition have produced an excellent catalogue of their exhibits, which contains a great deal of valuable information on the production and uses of the specimens in question. In the first group, devoted to food products, a series of analyses is given of the principal grains and pulses, fungi, cucurbitaceous fruits, &c.

The fruit of the Maidenhair tree (Gingko biloba), under the name of Ginnan, is described as an acrid poison, so poisonous indeed that if the juice touches the body boils will immediately be produced; any one eating the fruit raw is soon affected by the poison, but when roasted its poisonous properties disappear entirely, and there has never been a single case of poisoning known to arise from its use when roasted.

Lagenaria vulgaris—Kan-pio—dried fruit.—The method of preparing is as follows:—The first step is to cut off the extremities, then the seeds and pulp are taken out, the fruit is then cut into lengths or strips, which are dried by hanging it on sticks. It can thus be preserved for a long period if kept in proper vessels and closed tightly. To prepare it for food it is boiled with water, soy, sugar, sweet wine.

Agaricus campestris—Shii-take.—The following is given as the mode of growing Mushrooms. Various tall trees are cut down, marks are made by knives, and the trees left for two years upon the ground. On a winter day the timber is cut into pieces and the logs left inclining to a fence or made into square piles and left alone for from two to four years. Mushrooms then begin to grow in rainy seasons. They are afterwards covered over and the full-grown ones are picked. These are called "Spring Mushrooms," to distinguish them from those which grow in the autumn, and which are called "Autumn Mushrooms." The gathered Mushrooms are compressed with Bamboo sticks and dried by exposure to the open air or to fire.

Gelidium corneum—Agar-agar, or Kanten.—The Gelidium is soaked in water and pounded well in a mortar until bubbles are formed and the colour becomes greyish; it is then poured into a large basket, dipped in water, and stirred until turbid water arises. The mass is next spread upon a mat made of Bamboo or reeds, and after thus drying it is put into a mortar again and hot water poured upon it. It is then boiled at a gentle heat, and when the weed becomes pasty it is poured into a linen bag and squeezed into a vessel and left to coagulate. The jelly is cut into threads and frozen by exposing the pieces to intense cold in thin layers upon Bamboo mats.

Kanten is used as a material in making confectionery and also as food. In summer it is prepared by pouring hot water upon it, and leaving it to coagulate. It is then cut into fine threads, mixed with water and seasoned with sugar or soy according to taste. It is also used for purifying turbid "sake" or rice spirit.

Frozen Kouniaku is prepared from the tubers of Conophallus konjak, which is pounded and coagulated by the action of lime and then frozen by cutting the Kouniaku into thin slices, drying and afterwards freezing it by exposure to intense cold. It is used as food after soaking in warm water.

Katakuri Starch.—The bulb of Erythronium dens canis is crushed, washed with water, and decanted. The precipitated starch is collected, spread upon mats, dried by exposure to the sun, and finally ground into a fine powder. It is made into a kind of vermicelli called Katakuri meu, and is chiefly used in making confectionery, or is made into a paste by adding hot water. It is served with sugar, and makes a very delicious food.

Kuzu Starch is prepared from the root of Pueraria Thunbergiana by pounding it, placing it in a tub with water, which is stirred, and afterwards filtered through a linen bag. The starch after settling is washed and decanted several times, and finally dried. It is principally used in confectionery and may also be served with sugar by making it into paste with the addition of hot water. It is not unfrequently used in cookery. It is remarkable that the stems of the plant yield a strong fibre which is used in Corea for making a textile fabric very strong and similar in appearance to an ordinary kind of coarse linen. Samples of this were exhibited at a recent meeting of the Linnean Society.

Warabi Starch is prepared from the root of the Brake Fern (Pteris aquilina), collected in the season when it is withered and no young shoots are to be seen. For this purpose the root is collected, cut into pieces, pounded, washed, decanted, and the settled starch is collected, and finally dried. It is mixed with Wheat-flour or Rice-meal, and made into cakes, or when made into paste by boiling with water mixed with the astringent juice of Persimmon, it is used for joining paper together, and the joint does not part even if exposed to rain; hence it is widely used for this purpose.

Umiboshi: Salted and Dried Plums.—There are two ways of salting Plums, one to put three "go" of salt upon one "sho" of Plums into a tub, for about ten days. The Plums are turned over, and then again put away for a week, when the same process is again gone through. The other way is to fill a tub with Plums, and sprinkle over them eight "shos" or a "to" of salt. In both of these modes of preparation the plums, after being kept in the brine thirty days, are arranged upon straw mats, and exposed to the rays of the sun for seven days. Then Shiso (Perilla arguta) is dipped into the juice produced by the mixture of salt and Plums, and is exposed to the rays of the sun, and set aside again for several days. When the colour changes to a beautiful red, it is then exposed to the open air for two nights, during which time the sourness somewhat disappears, and a very delicious flavour is produced.

Preserved in an earthen jar, and closely sealed with a thick paper cover, this preparation will keep for over ten years. It is very valuable as a provision in campaigns and on voyages. Moreover, the taste remains unchanged, even to the palates of those suffering from high fever, or of those whose sense of taste from the same cause has been much impaired; therefore, it is kept in almost every house, and is especially used for invalids.

Kasadzuke.—This is a preparation of white Melons. To prepare it the Melons are cut open, and the seeds removed with a Bamboo spatula; a small quantity of salt is spread over them. After the juice of the Melons has been absorbed into cotton cloth, a mixture of Sake residuum (a kind of spirit from Rice), and a certain proportion of alcohol, is gradually poured upon the bottom of an empty tub; upon this the salted Melons are laid, then a layer of wine residuum, and another layer of Melons, and so on, till the cask is full; it is then headed up, and kept for four or five months before using. In Japan at the present day this substance is served at the close of every meal, when warm water or tea is drunk. When taken after eating meat or fish it is very wholesome and delicious. At breakfast, when there is only boiled Rice and miso soup, and no fish or vegetables it helps to complete the meal. It is also a good accompaniment to a cup of tea.

Soy.—Two preparations from the Soy Bean (Glycine soja), besides that already referred to, deserve mentioning—namely, miso, a fermented substance; and shoyu, or soy itself. The first is a curious preparation, described as follows:—There are many ways of making miso, differing very little from each other; the kind containing the largest quantity of yeast is considered the best. The usual mode is after soaking Soy Beans in water for about two hours to put them into a suitable vessel and steam them; then, after mixing them with salt and yeast, they are removed to wooden plates; then the ingredients are very evenly mixed, the liquid is put into casks, and is then left untouched

for upwards of a year. Another method is to soak a quantity of yellow Soy Beans in water for a night, then boil them in a large kettle, and as soon as the water in the kettle has evaporated, and the beans show a reddish-yellow colour, they are removed to a mortar and pounded, after which they are placed on mats. When they are thoroughly cooled they are shaped into balls as large as hand-balls, cut with a knife into flat pieces about an eighth of an inch thick, and placed on mats shaped like scales of fish. As soon as mould appears upon them they are taken, crushed into small pieces, and exposed, to the rays of the sun for a day or two. When nearly dry, salt and water are added to them, and the whole is pounded in a mortar and then left in a cask for a month or two, and sometimes longer, when the preceding process will be repeated. Finally, if it is sealed up in casks it will never deteriorate. It is in prime condition when three years old. It forms one of the most necessary articles of food in Japan, and has been used from time immemorial, both by nobles and men of inferior rank. It is made into a soup, and is one of the courses served up as a principal article of everyday diet. The mode of preparing the soup is to rub the miso around an earthen bowl, into which a suitable quantity of water has been poured. It is then filtered through a sieve, and vegetables added according to taste; the whole is then boiled and served up. Miso is also used to give an agreeable flavour by mixing it with other food, and it is likewise mixed with condiments, as Japanese Pepper, Ginger, Horse-Radish, Chillies, Sesame, Poppy seeds, &c.

Soy or *Shoyu*, is perhaps the chief product of the Soy Bean. It consists of a mixture of these Beans, Wheat, salt, and water. The mode of preparing it is to thoroughly boil, after washing in a cask with water, fifty parts of Beans, and to parch about fifty parts of Wheat in a pan for a little while and thoroughly boil it, after grinding on a stone mill: when these two substances are mixed together and kept in a warm room for about four days, the substances are converted into a yellow flour-like matter; this is yeast. This yeast is then thrown into a mixture of salt and water, and afterwards thoroughly cooled, then boiled in a large kettle, and stirred with a Bamboo instrument twice a day in summer, and once a day in winter. After the lapse of three years, the sediment is poured into a bag then put into a small tub and submitted to strong pressure by means of a bar at the end of which hangs a heavy weight. The fluid expressed is poured into a kettle and submitted to a heat of not more than 80°; it is again removed to a large tub and set away for a night, when it becomes a deep black colour, and acquires a very delicious taste. Soy is one of the most valuable foods, and is in daily use; mixed with several kinds of food it imparts to them a delicious flavour. It is universally liked, and is really indispensable in the Japanese kitchen. The quantity annually consumed in Japan is extremely large, and of late years the article has been exported.—*Gardeners' Chronicle.*

INDIARUBBER IN GUATEMALA.—We learn, from Mr. Consul Bennett's report on the trade and commerce of Guatemala during 1883, that the vexed question of tapping the trees, or cutting them down, was under discussion. What happened with the guttapercha trees (*Dichopsis gutta*) in Singapore and Penang forty years ago, by which the plants became well-nigh exterminated in those islands, has since been enacted in other countries with other useful plants. The Guatemala rubber tree (*Castilloa elastica*) is a valuable source of this important substance, and should be carefully preserved. Consul Bennett says those in favour of cutting down allege that the quantity of rubber extracted by so doing is only equal to what would be collected in five or six tappings, after which the tree would die, and consequently that the yield, being immediate and of equal quantity with what would be given by a series of yearly tappings, and the tree in both cases dying, it is more to the interest of all to cut the tree down at once. This course, however, is forbidden by a Government decree. It is possible the law may be rescinded, and the practice allowed on condition of two new rubber trees being planted for every one cut down.—*Indiarubber and Guttapercha Journal.*

THE YIELD OF TEA on Aberdeen estate is reported by the Manager in another column to have been for 1884 over 1,000 lb. per acre of made tea from the 9 acres five years' old. In this connection we see the old dishonest and untruthful game started by our morning contemporary and a correspondent of referring to the *Observer* as inflating the Tea Enterprise —the fact being that the only (and repeated) editorial warnings have been given in our columns and that the "Times" has been saying far more about "the thousand pounds an acre." But so it was in respect of "coffee": from 1872 onwards, we warned men to buy or plant on the basis of 3 cwt. an acre and 80s a cwt. (when the price was over 100s) and yet we got the blame of the Cash Credit inflation which we had expressly condemned!

WITHER BLIGHT ON TEA is thus noticed in the proceedings of the Agricultural and Horticultural Society of India:—Extracts *of letter received from John Ramage, Esq., Manager, Tingri Tea Co., Limited,—No. 650, dated Dibrooghur, 11th December 1884.* I am sending you today by sample post, shoots or branches from three blighted bushes, and trust they may reach in such order as to pay examination, each has its history wrapped round it. *Enclosure.*—"Tea Planter's" remarks refer to this identical blight, but I told you in mine of 12th ultimo, what little effect cutting down had upon it. On the first appearance of "blackened" leaves, I have examined the bushes affected down branches, stem and roots, and could find no trace at any time of the white thread like parasite which afterwards appears, and which I believe to be the outcome of the original attack of wither, this opinion is open to consideration, as I note the parasite, after showing does not run down the stem, but up the shoots that are giving leaf, and displays a sort of frost upon the leaves which die. The white thread runs to within 10" or 12" of the ground and to get rid of it by cutting to that, wants some thinking over. My opinion is that some atmospheric influence has to account for the leaf getting black in the first instance, the bushes attacked being ready to receive the same, just as a run of any epidemic will select its victims promiscuously, and the only remedy I can see, and it may be worth a trial, is to have the bushes attacked stripped of every leaf on the first sign of "sickness," so that if the parasite has been created it may die from want of food. It is evident, it is not migratory, else why should it group so. With these remarks I close on wither blight for the present.

THE AFRICAN OIL-PALM (*Elais guineensis*).—The *Archiv der Pharmacie*, October, 1884, contains a paper by A. Meyer, Pharmaceutical Docent at the University of Strassburg, on the structure, habitat, uses, &c., of the African palm-tree (*Elais guineensis*), from which it appears that although this palm, which is the only one of importance from a mercantile point of view, has now its chief habitat in Africa, it must have originally come from tropical America, where a similar but inferior palm (*Elais melanococca*) is still indigenous. That nearly all parts of palms are of some value is well known, and this is especially the case with *Elais guineensis*. The leaves are used by the natives for roofing and wicker-work, the fibres at the bottom of the petiole serve for textile fabrics or caulking boats. From the juice a kind of wine is prepared, and the fruit and seeds yield the palm oil of commerce. The oil, which is commercially the most important product of the African palm, is obtained by crushing the fruit and extracting the oil with boiling water, or by allowing the fruit to ferment, whereupon the seeds easily separate, and the oil is melted out from the former. This constitutes the crude oil, which is then handed over to Europeans for refining, either in factories not far from the source or in Europe. Palm oil and palm seeds are imported solely from Africa. The trade is in the hands of native brokers, who buy the oil from the negroes in exchange for good dust, strips of iron, brass, copper wire, and the like. The centre of the palm-oil trade consists of the oil villages Talifer, Fishtown, Snaketown, and Bonny, on the shores of the River Bonny, the latter village being the most important, the business done there alone in oil and seeds amounting to several thousand tons a week.—*Chemist and Druggist.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE *LANCET* ON CEYLON TEA.

Panadure, 28th Jan. 1885.

DEAR SIR,—I am sure you will be glad to give publicity to the annexed extract from the *Lancet* of 6th Dec. ast. Under the head of "Analytical Records" is noticed:—

CEYLON TEA: PURE CEYLON TEA GROWN BY THE CEYLON COFFEE COMPANY.

(*H. Hewetson & Co., 59, Mark Lane.*)

"Genuine young tea, of the kind which attained such popularity in the Ceylon stall of the late Health Exhibition. The leaf is unfaced, as is shown by the fact that we found in it only 5·24 per cent of ash which agrees with that found in the best Assam. China has a formidable rival in Ceylon."

This is very flattering indeed, and the statement all the more valuable in face of the following editorial note which heads the column:—

"Of the numerous articles of food and medicine submitted to us, we select such as we think important to the medical profession and the public. Samples of these are bought by us in the usual way, and the result of our examinations reported."

—Yours truly,

"ARBORICULTURE" FOR PLANTERS: "TREE ENEMIES AND RENOVATORS."

4th February 1885.

DEAR SIR,—I have been much interested in your descriptive notes upon *Albizzia stipulata* in your issue of 30th January and again of the 2nd instant along with Mr. Wm. Ferguson's remarks. I am greatly surprized at its qualities as a renovator in tea cultivation, being well-acquainted with all the species of this tree indigenous to Ceylon and some ten species known in India.

This tree and the other varieties are found growing about native villages, open forests, or by the edges of forests on the Kandy side, at an elevation of 2,500, and on the Uva side up to 3,500 feet. I have had this tree growing in a field of coffee and cinchona and innot one instance was the coffee of any value underneath these trees. They are rapid-growing trees with large surface-feeding roots.

There must be some peculiar substance in the roots when the tea plant is said to flourish so well. Nevertheless, it is well-known that "acacias" all over the world are injurious to the growth of plants in their proximity. I have planted a few tea plants here under a tree, and will be pleased to report the progress they make by the end of this year.

The timber is useful for light work, and makes splendid charcoal.

Symplocos (order STYRACACEÆ) contains 160 species found in the warmer parts of Asia, Australia and America. In India 64 species are known, and mostly large valuable timber trees.

Thwaites gives 16 species in Ceylon and all large trees found in the forests of the Central Province.

Symplocos spicata (nom. vulg. "Bombu") is a fine tree with heavy, hard and durable wood, used in house-building, &c. *Symplocos obtusa, S. hirsuta, S. elegans, S. cordifolia* and *S. coronata* are all valuable timber* trees and often used for building purposes.

The stem and root bark of many contain dyeing properties.

Symplocos racemosa, a small tree, is known in India with yellowish strong and compact wood. The bark of the root is of great value and used in Rajputana for dyeing red, and also used in medicine.—The bark furnishes one of the red powders known as "abiz" cattered by Hindus in the festival of the hoolee. J. A.

* As we mentioned, in noticing the identification of *S. obtusa* in the reserve forest of Abbotsford, the Sinhalese carpenter who accompanied us and pointed it out spoke very disparagingly, even contemptuously, of the timber.—ED.

THE YIELD OF TEA ON ABERDEEN ESTATE LOWER DIKOYA DISTRICT, CEYLON.

Aberdeen Estate, 5th Feb. 1885.

DEAR SIR,—As promised I send you the following detailed figures of monthly yield (of made tea) per acre from the 9-acre field of this estate now five years old, viz.:—

January 1884, 78 lb. per acre made tea; Feb. 88; March, 126; April, 83; May, 106; June, 127; July, 84; August, 33; September, pruned; October, 99; November, 132; December, 48. Total for the year, 1,004 lb. per acre—made tea.

About one-third the acreage of this field being of rather poor soil, I attribute the heavy bearing to close planting ($3 \times 2\frac{1}{2}$) and *early low topping*.

I see in your *Weekly* sheet sent as Supplement to last night's *Observer* that the yield &c. of tea from this estate along with some others has been the subject of comment by correspondents in the local "Times," and that I as manager am accused of withholding much needed information. Not being a subscriber to that paper nor having seen a copy of it since 20th December last, I may be excused from replying; in any case, I decline to reply to *anonymous* correspondents, having already subscribed myself

SUPERINTENDENT.

COCO PALMS AND BEETLES.

Colombo School of Agriculture, Feb. 11th, 1885.

SIR,—I have got a small coconut plantation in Panadure. The estate is about a quarter of a mile from the seashore. The soil is mainly of a peaty character, having been formed by the decay of vegetable matter applied to the land with the intention of raising its level. The coconut trees on this land have been thriving well, and they have been in bearing for the last year. But now their stems are being injured by the cockchafer and the grub, and some stems have fallen down by the destructive effects of these insects. Will any of your readers kindly inform me through the medium of your journal what means should be adopted to put a stop to this?—Yours obediently,

J. F. G. RODRIGO

[Our correspondent will find full information on the subject in the book on "Coconut Cultivation" which we shall publish shortly. Meanwhile, we may say that little can be done in the way of remedy for grubs, though much can be done for prevention: the fibrous sheath with which the ptems of young trees are surrounded should be removed, as stherwise beetles will lay their eggs there, which will oevelop into grubs that will destroy the trees when older.—ED.]

CARDAMOM CULTIVATION IN CEYLON:

ALL THAT GLITTERS IS NOT GOLD, AND ALL THAT ARE CARDAMOMS IS NOT A FORTUNE.

SIR,—Cardamoms generally in Ceylon have been a fair success, in some instances a great one. On the other hand more than one clearing throughout the country has sigoally failed to crop, and sometimes, though one portion of an estate has done well, another part has borne badly.

As cultivation extends it becomes evident that like everything else cardamoms have their peculiar enemies, pests and sicknesses. Harvesting in India is usually carried on, I understand, for some three years only, and then the land is abandoned.* Probably as the average Ceylon garden will continue for a similar period, and then rapidly fall off till it ceases to be profitable. In very favorable circumstances, however, at least double the number of these good years may be expected.

* That is the mode adopted by the natives of Travancore, who go into the forest, fell a certain number of trees, allow the plants to spring up, and in due time gather the produce, the felling process being repeated as crops lessen. But this surely cannot be the system on the Coorg estates of Mr. Middleton and others.—ED.

By last year's exceptionally dry season most cultivators suffered disastrously, by the loss more or less of blossom and light fruit, while some who had ventured into risky localities experienced total loss of both crop and plant.*

A product so extremely valuable, and so easily stolen, is peculiarly liable to theft, while from the luxuriant growth of the vegetation, detection is difficult and protection expensive. In some exposed situations robberies became so frequent and the cost of watching so great, that cultivation almost ceased to be profitable. In one instance, during the course of a single night, the whole crop of a small clearing away at the top of an estate was ruthlessly cut off and removed.

Grub threatens to become a formidable enemy.† Here and there through some clearings stools may be seen flattened down as if a large stone had fallen on their centre, while by a slight pull stems may be withdrawn without difficulty. This may arise from the presence of rock at bottom, but more usually, I fear, it is due to grub. Again a whole field may generally become subjected to this pest, when the leaves turn yellowish, the stems fail to reach mature growth and crop ceases. I have known a fine clearing so affected suddenly, fall from a yield of over 500 lb. an acre one year to practically nothing the next. Seemingly the only cure is time, or the heroic remedy extirpation and renewal.

Excepting the early days of a plantation, monkeys seldom do much mischief and then only wanton, but wild pigs when they can get admission will always do considerable damage. A gun for monkeys and a fence for pigs become necessities in the neighbourhood of much jungle or chena.

There is an ailment of which little is spoken, perhaps because it is attributed to wind and drought, but it is often to be found badly in sheltered spots and during the rainy season. The leafy portion of the stem, particularly the upper leaves, get blotched and speckled with yellow or brown spots, become frayed, something like the leaf of a coconut tree suffering from beetle, and then rapidly decaying, falls off, leaving the mid rib bare and withered. If anything, cardamoms in the open seem to suffer most from this; but though it is yearly on the increase, and undoubtedly affects the health of the plant, it does not appear so far to diminish the crop.

A poor-looking stiffish hard dry soil tolerably free from stones is unfavourable for the cropping if not the growth of cardamoms. To be suitable, a soil can hardly have too much vegetable mould or latent moisture, though dampness of atmosphere is of more consequence than of soil.‡

Ordinary wind may be met by close planting; but when cold and dry as well as strong it becomes fatal.

In some parts during the setting-in of the north-east mousoon, extensive blackening and rotting of fruit-stalks takes place. This is put down by some to prolonged wet with a rainfall of, say over 50 inches per month, but I think it is more the result of continued damp following a long and severe drought that has already weakened if not killed the fruit stalk. Will Dr. Trimen kindly say whether this part of the plant should be called a scape, a race, or a raceme?

The black fungus has been detected on cardamom leaves, but only, I think, when near affected coffee, and, as might be expected, without apparent injury to the plant.

The extent of very suitable land is limited greatly by climate and soil, and as this new product is not a high cropping long liver, it is very doubtful if, unless during the next two years, there will be any over-production in Ceylon. At the end of March next, would you please publish shipments, as by then at least two-thirds of the crop should have gone forward.

Prices have already very considerably fallen, and they may likely for a time go much lower still; so that any temptation to rush further planting should not now be indulged in. Local opinion still differs as to the propriety of bleaching the produce. No doubt it weakens the flavor and aroma of the spice; but, so long as it secures a better price in London, it may be desirable, from financial motives, to continue doing it.

As regards the two kinds, the Mysore is undoubtedly the hardier in every way, yields a larger fruit, and is more easily picked but I can't help thinking the flavour is coarser, and the yield less.

CARDAMOMUM.

P. S.—In connection with the above, it is interesting to note how two other kindred species—pepper and pimento—are also gathered before reaching full ripeness, and how the two, pepper and ginger, also so frequently undergo a whitening process to the prejudice of their strength, before reaching the hands of the consumer.

[This is a very valuable and timely contribution to the history of a plant, the cultivation of which has, naturally, been taken up very extensively, and which, apart from the drawbacks mentioned by our correspondent, has already been overdone. The worst of products like cinnamon, cardamoms, vanilla and such like is, that, being luxuries and not necessaries of life, the market can be so speedily swamped. No doubt sugar, coffee and tea, now absolute necessaries to a large proportion of the human race, have been over-produced. But, in the case of these and similar articles, plenty and cheapness largely and rapidly stimulate consumption, so leading to further demand at remunerative prices.—ED.]

* As happened to cacao in some places.—ED.

† Has this, the most destructive, perhaps, of all pests, been known to attack the roots of the cacao plant?—ED.

‡ We suppose there is a limit as regards wet, for on a Yakdessa estate with over 250 inches of annual rainfall, we saw cardamoms which grew, but could not produce fruit enough to pay for the gathering.—ED.

MAURITIAN SOCIETY FOR COLONIZING MADAGASCAR.—The Mauritian public should heartily thank the Mauritian Society for the Colonizing of Madagascar, for it has been established at the very moment when most wanted. There are numbers of persons without employ, there are many who fear to lose their occupation very soon; let them go to Madagascar, for the society is formed with the express intention of aiding and assisting all persons who may wish to emigrate to Madagascar. [Yes, and to become French subjects.—ED.]

LIME FOR AGRICULTURAL PURPOSES is thus noticed in the "Agricultural Notes" of the Melbourne *Leader*:—A patent has been taken out in London for preparing and applying lime for agricultural purposes. The inventor specifies the employment of finely divided or pulverized anhydrous lime, such preparation being effected either by grinding the burnt limestone, as taken from the kiln, into fine powder or by other means, such diminuted or pulverized lime being then brought into contact with the soil and covered in or caused to be mixed therewith either by drilling, ploughing, harrowing or otherwise. The powerful affinity the anhydrous lime in powder has for moisture generates an extraordinary amount of heat and this action produced in the soil by lime with the moisture contained in it is of the utmost importance as to the chemical affinity of the lime combining with the constituents there present, and rendering them more efficacious as manure, and also as a more powerful disintegrator than lime applied in the ordinary way, while it at the same time reduces the cost of liming land for agricultural or grazing purposes.

COFFEE CULTURE IN AMERICA, ASIA AND AFRICA.

We have received a copy of the Dutch edition of the report on coffee culture in Brazil, by Mr. Van Delden Laërne, of the Java Civil Service, the comprehensive title of which runs thus :—

Brazilië en Java. Verslag over de Koffiecultuur in Amerika, Azië en Afrika Aangeboden aan Z. E. den Minister van Koloniën door K. F. van Delden Laërne, Referendaris bij het Departement van Binnenlandsch Bestuur te Batavia, door de Nederlandsche Regeering belast met eene zending naar Brazilië, in het belang van de koffiecteelt en den koffiehandel in Ned.-Indië.

There are to be editions in French and English of the work, and the Dutch title is done into "English as she is spoke," after the fashion following :—

Brazil and Java. Report on the Coffee-culture in America, Asia and Africa, offered to H. E. the Minister of the Colonies, by C. F. van Delden Laerne, Referendary at the Department of the Interior at Batavia (Java), charged by the Dutch Government with a special mission to Brazil on behalf of the Coffee-culture and Coffee-commerce in the Dutch Possessions in India. Translated from the Dutch. I vol. 8vo. With maps. Cloth. Price 1 Guinea.

"Offered," of course, means furnished or submitted to the Minister of the Colonies. We have ordered the English edition, and we must wait for that before reviewing the report or extracting from it. But we may say at once that the information collected seems ample and well arranged, and that the value of the work is greatly enhanced by the two splendid maps attached to it. The first, prepared by Professor Orville A. Derby, so lately as 1884, indicates the geological formations of the coffee area of Central Brazil, an area embracing the country between 19° and 24° South latitude, and somewhat beyond 41° to 48° West longitude. The space includes the larger portion of the three great Provinces of Rio de Janeiro, San Paulo (Santos) and Minas Geraes. Six colours are used to indicate the different formations. The second map embraces the same area, but here Mr. Van Delden Laerne has laid on colours to indicate the Rio and Santos zones, respectively, while railways in operation, under construction, and contemplated, are laid down and give a vivid idea of the extent to which railway facilities have aided slave-labour in swamping the markets of the world with coffee. On this map there is a very interesting diagram of the celebrated San Paulo railway which at one place goes up an almost precipice by means of "lifts" similar to those which we so happily escaped in Ceylon. The "Lengteprofiel van de Spoorwegbijn (steam-road-line) van Santosnaar S. Paulo en Jundiahy" gives a very vivid idea of the character of this extraordinary work, by means of which trains *leap*, as it were, from the lowcountry to the mountain plateau of San Paulo. From the table of contents we gather that there is a full account of the "Spoorwegen," and that "Slavernij en Emancipatie" are fully discussed, also "Immigratie en Kolonisatie,' with "Klimaat," &c. But we hope to give an idea of the numerous subjects embraced in this volume, and, perhaps, translations of some portions of the contents, in a future number.

Vanilla.—Our Vanilla Market is still dull. There have been no sales. All the prepared vanilla is shipped for the planters' accounts. This is the first time for many years that this has been the case. It must be said, however, that buyers, in presence of the unfavorable news from Europe are not disposed to give the prices demanded, and prefer to abstain from buying. [Mauritius and Bourbon so fully supply the market with the aromatic pods that we are not sanguine of the success of experiments in Ceylon.—Ed.]

"CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AND ENERGY :"

BOYHOOD THE HAPPIEST TIME OF LIFE—CEYLON IN OLD DAYS : ITS CONQUEST BY THE BRITISH—THE ROAD TO KANDY : HOW IT WAS MADE AND ITS EFFECT ON THE REVENUE OF THE ISLAND—THE RISE AND FALL OF THE COFFEE INDUSTRY—THE RUIN CAUSED BY LEAF-DISEASE NOT CONFINED TO THE EUROPEAN COMMUNITY—NEW PRODUCTS—THE NEW KING, TEA : ITS UBIQUITY OF GROWTH—DANGERS OF HURRY—ADVANTAGES ENJOYED BY CEYLON TEA PLANTERS—LIKELIHOOD OF A FALL IN PRICES—COST OF PRODUCTION—THE BEST TEA SOIL—CHOICE OF PLANTS—HYBRIDS—NEW AND OLD LAND—ELEVATION AND RAINFALL—COST OF OPENING A TEA ESTATE OF 100 ACRES - PROFITS—A HEALTHY CLIMATE—THE CEYLON PLANTERS—DISTRICT ASSOCIATIONS.

My dear Mac D———, —Your letter came duly to hand, and I was at first a little excited about how you discovered my address, but I suppose you came across Ferguson's Directory, which travels far and wide over the face of the earth, or perhaps you may have met with one of the few old planters who may have known me in other days. I never was a very conspicuous person, but for the last dozen years nothing could be more obscure than my existence. You remind me of those winter evenings 51 years ago, when some little assistance old Mrs Mackay solicited for her grandson, in getting up his lessons, led to the nightly gathering of half-a-dozen boys round me, to be coached in the questions the dominie was likely to ask next day, and then we indemnified ourselves with much fun and frolic for our hour of study. I have often thought that the days of boyhood, say from ten to fifteen, are the only real good times that life has to offer.

You wish me to give you my opinion of the Ceylon of to-day as a field of life work for a young man of twenty with fair talents tolerably cultivated, and who can command a capital of £2,000, two or three years hence if the life and work should be satisfactory.

The Ceylon of today is very greatly changed from the Ceylon that I first set foot in forty-four years ago. The Ceylon of that day was one of the poorest countries on the face of the earth. It had been conquered from the Dutch in 1796, and was kept by Britain at the peace, because it was not desirable that any foreign nation should have a footing so near our Indian Empire. A large garrison was maintained chiefly at the cost of England, and in 1815, the whole island was brought under British rule by the conquest of the Kandyan kingdom, which added something to the strength if not to the wealth of the Government. It was for the more secure military occupation of the new conquest that a road was run into the centre of the mountain zone. The Government of those days was not rich enough to have made twenty miles of carriage road in any direction on the system that now obtains ; but it had inherited from the native rulers an unlimited right of corvee, and by this custom all the unskilled labour required for the construction of the skilfully planned system of roads was supplied. Else it is not easy to see how the island could ever have become other than it had been for a thousand years, a land of forests and swamps inhabited by an indolent apathetic race, living from hand to mouth, decimated by famines from time to time, and keeping population in check by the practice of polyandry and female infanticide. In the towns on the sea coast, there was a mixture of other races, European descendants, half-caste Moors, Tamils, &c., and there alone the scanty capital of the island was concentrated, and the small trade transacted. A man who could give his daughter one hundred

dollars, say £7 10s, as her marriage portion was held to be in prosperous circumstances, and he who gave two hundred was called rich.

The public revenue in such a country was of necessity rather limited and consisted of a monopoly of the production of cinnamon, a salt monopoly, a tithe on the grain grown, a customs duty on the small import trade, and a few other small imposts, which with a pearl fishery at long intervals made up an average of something over R3,000,000.

It was into this state of affairs that the existence of a road into the central districts brought Europeans with money in their pockets, and in native opinion a mad desire to get rid of it. I do not propose to go into the history of coffee planting in the island, the capital and the lives it wasted, its see-saws of depression and prosperity till the great disaster that in ten years has reduced the production to one-fourth of the amount it once reached and in its fall has carried ruin into industrial pursuits that it created and supported. *Hemileia vastatrix* has not only ruined coffee planting but everything that even remotely depended on it. Except the purely native element that has lived its own life apart in the obscure villages unaffected by the changes that went on outside its economy as inherited through fifty generations of unenterprizing ancestors, and a less numerous but more important section of natives who made money when they had the chance and invested it in cocoanuts, cinnamon and other enterprizes that can now stand alone and save the country from ever falling back into the poverty-stricken, dead-alive state of half a century ago, even had European planting become a thing of the past, which was greatly desiderated by some members of the public service, but is not likely to come to pass yet awhile. The planters have fought their battle like a band of heroes. No sooner had the serious nature of the fungus become suspected than they began to plant all kinds of new products suitable to their respective climates, and that promised to pay for the cultivation, cinchona, Liberian coffee, cacao, cardamoms, rubber and tea.

On this last planters have taken their stand, and have selected it king instead of the moribund coffee tree. It is asserted that this plant grows luxuriantly over more than one-third of the surface of the island and from the sea-shore up to 7,000 feet, that it will pay to grow it on indifferent soil, but that in the most favoured spots unprecedented crops have been produced already, 900 lb. per acre and more expected when the bushes are more mature. but no one seems to doubt that 400 lb. is to be got got off almost any land, and that with proper machinery it can be put into the London market for 6d per pound, where it has already made a place for itself, inferior to none. While such are the opinions generally held by Ceylon planters. you may be sure they are not idly contemplating possibilities but rapidly carrying their theories into practice, and tea plants are being put down by tens of millions For good or for evil, Ceylon has committed itself to tea, and a great tea country it will become ; nothing will hold them back now, though I and others may howl ourselves hoarse, shouting *festina lente*. There would not be much to regret in this movement were it not that bad jât may result from the hurry, and the vast demand for labour may soon outrun the supply. and permanently increase wages without estates being thereby fully manned.

The present advantages of the Ceylon tea producers are a forcing climate, a railway that penetrates to the heart of the mountain zone, good cart roads into nearly every important district, a tolerably abundant and not prohibitively costly supply of labour—but it is said that competition is beginning to tell in what has hitherto been Ceylon's preserve ; and we are quite willing to believe that our average per acre will exceed that of our Indian brethren by twenty-five per cent. The only one of those advantages that has the elements of permanency about it is the climate that gives a tea harvest all the year round. In a few years India will match us in means of communication, while increased competition and cheap and rapid means of travel will tend to equalize wages all over India and Ceylon. By the time Ceylon sends her fifty or sixty millions of pounds of tea annually into the markets of the world consumption will not be able to overtake supply and a time of low prices will ensue, through which only the fittest will survive, namely, those who can give the finest qualities at the lowest cost of production.

It is most probable that here in Ceylon, where the most perfect machinery yet invented is in use, the lowest cost of production has been reached and we may take it as an established fact that it can never be produced at a lower rate in future, as the undoubted tendency of the age in this part of the world is towards a rise in the wages of labour as new industries open up new fields of employment and the condition of the labouring population improves with larger means. The best tea soil is a deep permeable loam, the richer in the common elements of fertility the better. As the soil falls off, either towards stiff clay or hungry gravel, the growth becomes less and less rapid and vigorous, yet tea will grow tolerably on soils that few other useful plants would relish. The most important point in the establishment of a tea field is the choice of plants. We have borrowed the word jât from India and speak of a good or bad jât according as it approaches to our ideal of what a tea bush ought to be. The tea plant is indigenous in the forests of Assam, and though it has been cultivated in China from time immemorial it is probably not indigenous in that country, and the forest tree of Assam and the cultivated shrub of China are specifically the same. When the two varieties were planted together the seed of either produced varieties without end. There is no hybridizing in the process but only what takes place in the case of all other plants that run to varieties. We have learned to call the plants we want to cultivate Assam hybrid, but instead of one hybrid we have a score of types and even within these no two plants are exactly alike in the size, form, colour and serrate of the leaf or in the habit of growth Many of the inferior sorts are unfit for cultivation and should be treated as weeds as soon as they declare themselves and their place supplied with better jât. The seed should be taken from the very best jât, but this even will not be safe if an inferior jât be allowed to flower at the same time within a bee flight

I do not know what set me on about jât, which can be of very little interest to you. but as it is written I let it stand If your grandson should finally decide on tea planting he will learn that and other things connected with the business best on the spot.

A large proportion of the tea already planted is on old coffee land, and there are plenty of old estates in the market, but for a young man proposing to settle new land is what I would recommend. The Government upset price is R10 per acre, but all choice lots are in future likely to be competed for, and it is hard to fix a probable price, but lower qualities outside the coconut region may generally be had for the upset price. If I were going in for tea on my own account I would prefer lots over 1,500 feet above sea level, as you are more likely to get regular rain than at a lower elevation, and frequent rain is a necessary element in successful tea-growing.

In the part of the country I reside in there remains no Government land. but at the current rate of labour a tea estate of 100 acres could be estab-

lished up to the plucking period with everything but machinery complete for £1,500. The establishment of suitable machinery would leave little of another £500, so that £2,000 of capital would be necessary for the purpose. We count here in rupees, and the rupee is equal to 1s 7½d more or less.

For the returns from the property so established we will only estimate 300 pounds per acre, costing £10 and selling for 1s per pound all round, £15 being a return of 25 per cent on the capital. I cannot say what the same extent might cost elsewhere, and under other circumstances. I have taken a low yield compared with what has been achieved in other districts, 600 lb. per acre having been obtained at an elevation of from 5,000 to 6,000 feet and from 800 to 900 lb. on choice spots from 2,000 to 3,000.

There is perhaps no part of the world more healthy than the tea region of Ceylon: some authorities even assert that some of the mountain districts possess the finest climate in the world.

It is an easy journey of ten hours from Colombo to Nuwara Eliya, the highest town in the island, where frosty mornings are common in the season and with the exception of the outlying province of Uva any of the planting districts may be reached in one day from Colombo.

Among the planters of Ceylon there is a large proportion of exceptionally able men, and the whole body form a well-informed and highly intelligent class, now pretty generally turned into conventional subjection by the presence of many ladies. In all the large districts there are Associations that meet periodically to discuss local matters and bully the Government, a duty they perform with more energy than effect, for, "your dull ass will not mend his pace for beating." L.

CACAO AND ITS ENEMIES.

All results of practical experience are valuable, and, therefore, the public will appreciate the contribution made by Mr. J. R. Martin (see page 702) to our knowledge of cacao cultivation and the serious difficulties by which in an early state of the industry it has been attacked. Mr. Martin is, of course very safe in making the statement that "planters differ widely as to the *injurious effects* of the *ravages*" of *Helopeltis Antonii*, as well as in the proposition that good soil, fair rainfall and careful cultivation, in the case of cacao, "may now be said to be a recognized *sine quâ non*." We should think so. Mr. Martin desiderates the opinion of a scientist, but on the question of the "injurious ravages" of *Helopeltis* Dr. Trimen has spoken, and with no uncertain sound. We do not suppose that he or any other scientist would support the idea suggested by Mr. Martin that *Helopeltis Antonii* injects any specific poison into either stems or pods. What the mischievous bug does is to insert its proboscis, a most formidable pumping instrument, and suck out the juices—the very life blood—of the portion of a tree on which it operates. Blackening and decay naturally follow, and in proportion to the number of the insects and the extent to which they attack a tree is the mischief done. The really valuable point in Mr. Martin's paper, is his confirmation of the conclusion arrived at in Java and stated by Dr. Trimen and others here, that *Helopeltis* can be successfully kept down, if not exterminated, by the collection and destruction of the insects in their various stages. The suggestion to burn affected branches and pods is also valuable. This fact is a great corrective to any tendency to "scare," as well the other fact that the suffering of cacao last season were largely, if not mainly, due to the excessive drought. Mr. Martin thinks that the snuffing out of many insuitable places is not matter for regret, but we suspect the owners of such places, who have purchased experience so dearly, very sincerely regret the loss of capital unsuccessfully expended. We are glad, however, to agree with Mr. Martin that cacao cultivation in Ceylon is *not* doomed.

COFFEE PRODUCTION.

(From *James Cook & Co.'s Weekly Despatch*, January 16th.)

We print the undermentioned particulars, as a record for future reference.

	Tons.
RIO.—Available supplies interior for season 1884-5, 3½ million bags. Estimate of 1885-6 crop, 3½ million of bags.	206,000
SANTOS.—1884-5 crop estimate 2 million bags, available supply in interior, 2,250,000 bags. Estimates 1885-6 not yet given, but there is no sign of diminished production.	132,000
BAHIA.—Crop 1883-4 (1st October to 30th September), 91,540 bags against 108,798 bags.	5,384
JAVA.—Estimated crop, 1884-5, Government 1,031,000 piculs " " Private 250,000 " PADANG, a full estimate ... 120,000 " MENADO ... ... 15,300 " MACASSAR, TIMOR, &c. ... 150,000 "	93,000
It is expected that the 1885-6 yield will be large, and so far accounts about leaf disease do not cause uneasiness.	
CEYLON.—Yield 1883-4 proved to be 323,941 cwt. that of 1884-5 is not expected to reach 400,000 cwt, but not far short.	16,197
BRITISH EAST INDIA.—The last Export was about 15,000 tons. This yield likely to be later, though somewhat larger than last year, probably 16 to 18,000 tons.	15,000
Export, 1st July, 1883, to 30th June, 1884— Beypore ... ... 2,126 tons. Calicut ... ... 2,387 " Tellicherry ... ... 7,567 " Cochin ... ... 226 " Coffee is now arriving at the two latter ports in considerable quantities; the quality, so far, promises to be superior to last season's crops.	
COSTA RICA.—Last year's export was 269,513 bags, that of 1885 will at most be 180,000 bags.	13,475
VENEZUELA.—Exports for the past season (1883-4)— La Guayra ... ... 10,158,243 kilos Puerto Cabello, about ... 11,738,310 " Maracaibo (we can only estimate) 12,000,000 " Crop of 1884-5 was reported very good in some parts of the country, poor in others, but result likely to be an average yield.	33,900
PORTO RICO promises to be exceptionally heavy: generally assumed as 25,000 tons. Last year's export was exceptionally small, but we have not the figures, excepting from Ponce from 1st Jan. to 20th Nov., 1884, which was 2,917,159 kilos.	
HAYTI.—Last year's yield very short, about 350,000 bags. Deliveries this season began later than usual, owing to heavy rain, but the plant, it is thought, has benefitted from the same, the yield is large, and the quality is superior to what it has ever been. Some expectations lean to 600,000, others to 500,000, but 550,000 bags seems the most likely result.	19,500
AFRICAN.—Of the bold berry (Euconge), usually shipped from Ambriz, crop expected to be double that of the previous one. The Cazenga crop, shipped from Loando, also said to be larger than last year, when it amounted to 5,000 to 6,000 tons.	
NEW GRANADA.—A good crop, but the revolution just reported in Columbia (and private advices speak very seriously of the outbreak) will altogether preclude shipment until a settlement occurs.	
JAMAICA.—A good crop; no figures of export.	
MANILLA.—Export 1st January to 29th October, 1884, 110,802 piculs, against 111,417 same time 1883.	5,900

The next production is supposed about the same, 100,000 piculs; Zamboanga 9,000.

GUATEMALA is likely to be early, some arrivals possibly in December and January; fair promise for the future. The undermentioned estimates given by one long resident in the country, and well acquainted with the Trade:—

	1884-5.	1883-4.	
Guatemala Crop,	15,000 tons, against	13,500 tons	25,000
San Salvador	9,000 „ „	7,500 „	
Honduras	6,000 „ „	5,000 „	

CACAO CULTURE AND ITS ENEMIES.

REPORT ON THE CACAO PEST BY J. R. MARTIN, ESQ., YATTEWATTE, MATALE, TO THE PLANTERS' ASSOCIATION OF CEYLON.

CACAO PEST.—From the literature of this subject, which has been pretty voluminous, it is not possible as yet to gather many very decided facts, and although there is little division of opinion as to the existence of the fly, *Helopeltis Antonii*, planters differ widely as to the injurious effect of the ravages of the insect and its formidableness as an enemy of cacao cultivation. Recent experiments have proved beyond a doubt that the blackening of the pods and of the tips of the branches, is the work of the same insect, and also that in the pods at the least the fly lays its eggs which develop into larvæ in a period of from ten days to three weeks. It has yet to be decided whether *all* the damage to the pods is attributable to this process of laying and incubation. The disease in this stage is purely local, no one having yet asserted that even the complete blackening and withering of a pod has any injurious effect on the tree. The fly apparently attacks the shoot in the same manner as the pod and the question at once arises: Does it as a rule deposit its eggs here also? and is the damage, which results, the effect of the incubation of the larvæ or the result of poison in the bite of the insect. It has been confidently and most publicly asserted that the dying-back of large branches and complete decadence of cacao trees which has been sometimes noticed during the last year, is the result of the ravages of *Helopeltis Antonii* and on the other hand the most experienced cacao planters of Ceylon seem to be of opinion that this is due to local causes, such as unsuitable soil, want of shade, bad plants and bad planting, exposure to wind and the most trying season of drought which the product has ever known. On this point we require the aid of a scientist.

With a somewhat intimate knowledge of this district I have no hesitation whatsoever in asserting, that, although this pest has been *known* on cacao estates for the last three years, it is only during the past unprecedented season that the results which have been attributed to it have manifested themselves, further that dying back and dying out has no occurred to any extent (that may not be accounted for by drought) on any but poor and shallow soil, also that vigorous cacao in good soil even through the past seasont has not sustained appreciable damage from *Helopeltis Antonii*, and lastly, that with the return of the rains, (although the fly still remains on the estates) the so-called effects of its devastations have almost entirely disappeared

From the forgoing remarks it must not be assumed that I do not think *Helopeltis Antonii* worthy of attention. In the present state of planting affairs we must be prepared to combat every enemy which can in any way shake confidence in our industries and from what I have heard the practical eradiction of this pest from an estate is by no means an impossibility. The cacao husks should be burned when the seed has been extracted and the *small* pods which are often found blackened on a tree should also be consigned to the flames. My own investigations prove that in many instances these contain the eggs and larvæ of the fly. The prompt removal of these besides, from other reasons cannot but be beneficial to the tree. As to the removal and destruction of diseased branches there is great divergence of opinion; personally I have found it effacacious. I mention these precautions in addition to the more obvious one of catching and destroying the fly which is being carried out on several estates. It has recently been noticed that the fly does not extend its ravages rapidly but seems to confine its attacks to certain trees and portions of an estate and this renders the possibility of its easy eradication a likely one.

My opinion is that this pest is capable of inflicting considerable damage on cacao pods, but that as an enemy to the cacao tree it need not be seriously feared; with constant care; its injurious effects can be reduced to a minimum and the *scare* which was raised by the discovery of its devastation was altogether unjustifiable.

CACAO.—The recent unprecedented season has given cacao cultivation the most serious check which it has received since its establishment as a commercial product in the Island. And it has been recognized rather unwillingly that only with well-sheltered land, good soil and a fairly distributed rainfall can it be successfully cultivated. In other words many estates which have been planted with this product have been found to be partly or wholly unsuitable and the area of land on which men of experience would care to plant it is considerably diminished.

This is hardly a matter for surprize or indeed an unmixed evil. It is well-known that five or six years ago proprietors of unprofitable coffee estates rushed this product into worn out soil and that land was felled and planted with it, which had been pronounced too inferior for coffee or any other product. That such estates should have received their *coup de grace* during the past season cannot be looked upon as altogether a matter for regret; when cultivated with some extra product they may perhaps prove remunerative, whilst their existence as they were, was but a drawback to a most promising industry. On the other hand those cacao estates which have come through the past season in a satisfactory manner (and I am glad to be able to record that most of the cacao in this district has done so) may now be pronounced to have proved itself vigorous enough to withstand any enemy, excepting, perhaps a speedy recurrence of such a season. That cacao requires good soil, a fair rainfall and careful cultivation, may now be said to be a recognized *sine qua non* by all cacao planters, and it may be added that when these qualifications exist, the faith of those who should should know most of the product, remains as great in it as ever. It should be remembered that the majority of the acreage of cacao in the island is represented by some five or six gentlemen and that during the recent trying circumstances they have never lost faith in this cultivation. There were not wanting those who talked of cacao as "doomed," but it will probably be found on investigation that the practical experience of those who took up this cry the loudest was comparatively speaking absolutely *nil*. The best answer to those pessimists is the present satisfactory condition of all cacao grown under suitable circumstances, and the fine crop that has now set upon the older trees. It is therefore with no feeling of discouragement that cacao planters enter upon the new year.

CURING.—As regards fermenting and washing we have, I think, little to learn. An important point has however recently arisen, viz., if cacao dried by intense heat in a few hours is as fit for the London market as that dried gradualllly and slowly, if the fact it would cause a material alteration in the present system of our drying houses and the subject is therefore well worthy of investigation.

PREPARING IN COLOMBO.—It is still an open question if all necessary preparation cannot be effected on the estate as well and more cheaply than for the present rates in Colombo, and it is doubtful if the present system adopted by Colombo merchants of dividing cocoa into No. 1, 2 and 3 qualities is on the whole advantageous to the seller.

COFFEE AND "CONFUSION OF EPITAPHS" IN BRAZIL.

The *io News*, which has no mercy for Brazilian bombast, writes thus:—

We sincerely trust that H. M. the Emperor will take to heart the lesson read to him on the 14th by the spokesman of the *Centro da Lavoura e Commercio*, when inaugurating the 4th Coffee Exposition. There is a saying in Portuguese, that of holy water and presumption, each takes what he will, and certainly the *Centro* has filled about a column and a half of the *Jornal do Commercio* with what

is not holy water. "For the fourth time" says the gentleman "we are come before Your Majesty to fulfill the engagement undertaken before the Government of Your Majesty, before our companions in labour and before ourselves, to promote by every means within our power the economic and commercial relations of the greatest Brazilian industry." The improvement consists in exhibiting hand-picked coffee, which does not in any manner represent the bean as it is marketed, but only as it *might* be marketed. The *Centro* has combatted errors, and pointed out faults or obstacles to its activity, which it supposed, and still considers, the object and purpose of the glorious combat in which the legions of labor draw their swords (*degladiao*) against the barriers of errors and prejudices, which, if at one time they seem to yield (we are translating) to the victorious force of principles, at another rise afresh swollen and strengthened by the alliance of interested associates and feudalized oligarchies (there 's fine language !) banded and bound together in the interests of the few, against those of the many. What all this means, we cannot imagine. Whether, to borrow the expressive words of the commander of the *Cautious Clara*, "the bearings of this observation lies in the application on it," or whether the orator's, like the magistrate who had Mr. Pickwick arrested, ideas come together and knock each others brains out, we leave to our readers' decision. There are no feudal oligarchies in Brazil, unless they exist on the plantations, and we have heard that there the style is rather patriarchal, than feudal. Then comes a magnificent outburst of rhetoric, which recalls the gorgeous geographical vision seen by *Little Billee* from the fore-top rigging. "Nor can any other explanation but that of the purity and justice of our intentions account for the generous and attentive welcome, with which, from the Pacific Ocean to the Mediterranean, from the banks of the Mississippi to those of the Volga, across the most advanced civilization and the most opposing influences, we have been received through the long pilgrimage, hitherto considered fabulous, but now traversed to the advantage and glory of this nation and of those who honorably and worthily work therein." What the welcome was we do not know, unless it was that which met the free coffee at St. Petershurgh. "Sire," continues the orator, "whatever we may consider the value and merit of the labours we have undertaken in favour of the agricultural industry in Brazil; whatever results of this enterprize may appear—an enterprize that has achieved over others the merit of being held up as a model and as an example, nothing can exceed,—in our opinion equal,—the supreme intrinsic value (*valia*) of the affirmation of principles, which are in the present and will be still moro in the future, the most ample (*amplissima*) base upon which the country, which must in the near future represent the marvellous legend of a stupendous and incomparable wealth, will rise, grow and prosper." With exchange at 19 3/4 d. and the government trying to cancel interest guarantees, this seems rather crooked. However, we will go on. "This is the synthesis of progress through association. Between the first man who had to carry on his back the first merchandize (it could not have been Eve?) that served for the first barter (No! it was not Eve) and the superlative easy and cheap means of transport we now possess lies the whole series of improvements, which are due to the association of many individuals in behalf of industry in general." *Ergo* the more *commissarios* there are, the better will be the coffee; or, to take it another way, the more coffee there is the better will be the *commissarios*. "But it does not suffice that these lessons be learnt by those who work and produce. In constituted societies there exist two forces that must advance together; that of the people which has reserved to itself the obligation to produce, and that of the state, which has been charged with the mission of directing. If one, or the other does not faithfully and opportunely perform its attributes, these forces separate; their impulsive movement is out of harmony; the equilibrium of the entire social mechanism is destroyed." The people have taken upon themselves the obligation to produce coffee (and import maize from the River Plate) and the state must not emancipate the blacks, because that would cause discord in the music of the joint action of the two powers that are present in constituted societies. We have only to add; if His Majesty took the dose as presented to him by the *Centro da Lavoura e Commercio* at the inauguration of the 4th Coffee Exposition and was not ill after it, the imperial stomach is much stronger than ours; for such a conglomeration of self-praise, bombast and long words, should give any one a fit of indigestion sufficient to last until the inauguration of the 5th Coffee Exposition, whenever that may be.

The *Centro* is going to exhibit at New Orleans no less than 700 different samples of coffee, and no doubt unlimited hot coffee will be served out all round as at St. Petersburg. Considering that this display of tropical products is called "The World's Industrial and Cotton Centennial Exposition," and is being held to commemorate the first exportation of Cotton from the United States, what a satire does this suggest upon the enterprize of Brazil! It is time the *Centro* abandoned the narrow sphere of its operations and entered on a wider and nobler field of action. We quite agree with Sr. Ramalho Ortigao that the present state of agriculture and commerce throughout the empire forces on us the conviction that we are face to face with an intense crisis. But the crisis will not be averted by the legislation at which he hinted any more than by the importation of Chinese cheap labour. Facts havo to be looked honestly in the face; slavery is doomed to rapid extinction, and free labour and the *pequena lavoura* have to come to the front together. Vexatious laws have to be repealed, disabilities removed, facilities granted for the purchase and tenure of land, *nativismo* has to be discouraged, and immigration to be encouraged by every means. Old and destructive systems of cultivation have to be abandoned, and advantage has to be taken of all that modern science and research have done for agriculture. Let the *Centro* use all its great influence to further these ends and it will be rendering a lasting service to the country: nor is it yet too late to adopt the suggestion of the *Jornal*'s New York correspondent, and send some dozen of the most intelligent, earnest and inquiring among its members to read, mark, learn and inwardly digest all that is to be seen and learnt at the New Orleans Exposition. All the agricultural eggs have been put into the one basket far too long, and the time has come for their being distributed elsewhere. We shudder to think what would be the result were such a blight to attack our coffee plantations at the present time, as has already nearly disheartened the Ceylon planters!

THE WEST-INDIES AND PANAMA.—No. 3.

Taking the people of Jamaica collectively, I like them. They are as a rule well conducted, contented people, fond of their jokes, impatient of insult and bad treatment, and often generous and forgiving of injury.

They are quick to notice the manners of Europeans and like or dislike a man according to the way he behaves towards them; for instance, when passing a stranger in the jungle or "bush" they say "Good morning" promptly on being met half-way, but, if no sign is made by the stranger, he passes on his way and leaves the impression behind him that *he has got no manners*. When they meet each other, it is: "How are you today, my dear?" "Oh I'm so-so, I thank you, my love." "How are you today, my sweet pickaninnie?" "Pretty well considering; my daughter; jogging along nicely, thank you."

Friday is pay-day; Saturday is market-day. Don't forget that in Jamaica. All the green coconuts, mango, breadfruit, soursop and other fruits with tomatoes, pumpkins, beans, peas, skellions and other vegetables available are carried into market on neatly-painted wooden trays by the Jamaica girls in their cleanest gowns. On Saturday mornings, sticks of chocolate, bottles of honey and other nice things from the villages are exchanged for the more substantial items of bread, beef, flour, rum, beer, stout, &c.

The West Indian lives as well as he can: he likes his grog and cigar or pipe; meat or fish as often as he can afford it; bananas, yams, coco yams (*Caladium esculenta*) are his everyday "staff of life." He dresses himself and wife respectably for church on Sundays, and, if poor and living in the country, carries his patent leather boots in his hand before and after leaving the town. Of course, if the old woman is with him, she carries both pairs of boots.

"Have a glass of my beer, my dear, and help to support the widow." Could you resist that?

The Cumberland Pen Agricultural Show was a great

success and prizes were awarded for the following products:—Sugarcane, coffee, cacao, rum, pimento, limes, lemons, fresh butter, cheese, cayenne pepper, vinegar, lime juice, dry ginger, honey, wax, preserved fish, beef salted, starch, essential oil and other oils, tobacco, cigars, grapes, pickles, starches from banana plantation, pumpkin, yam, ipomœa, negro yam, Indian yam, breadfruit, white yam, cocos, &c.

The fibre industry was well represented, the steam engine working the machinery and fibre being manufactured on the spot.

I mention the above as a hint to your Government Agents in upcountry stations to promote new industries among the Sinhalese and Tamil population of Ceylon.

Jamaica, as all the world knows, is a great stock-breeding country, and pen-keeping pays better than sugar or coffee cultivation. Prizes were given for horsekind, cattle, sheeps and pigs, mules, turkeys, fowls, pigeons, ducks, and geese. Prizes as high as £10 were given for 1st class cattle down to £3 for fat steers and heifers. I was surprized to see such a spendid collection of beasts, and they were shown off to great advantage at Cumberland Pen near Spanish Town and Gregory Park.*

H. COTTAM.

THE SONG OF THE RUBBER TREE.

I.

The Golden Age and the Age of Bronze
May be left to the visions plastic
Of art and song, but a free response,
With a buoyancy gymnastic,
Is at present caught from the world of thought
For the Age of the Gum-Elastic.
T'is the song of the hour that grows in power,
With a rhythmic beat quite pleasant,
As of myriad things, shaking out new wings
For the pleasure of lord and peasant—
The song of the age, the pean free
That is wafted up from the Rubber Tree,
The song of the moving Present!

II.

From the wooded wastes of the Amazon,
From valleys old and Asian,
From the hot Nepaul, and the straits that crawl
Among islanded groups Malaysian,
The strange air floats from untutored throats,
Till at last, in a diapason,
Harmonious made by the roar of Trade
And the hum of the fabricator,
World-wide it flows, without let or close,
And none with a meaning greater,—
The Anthem free of avails to be,
The rare new song of the Rubber Tree,
Blest gift of the good Creator!

III.

A world of wheels, and of belts and reels,
Proclaiming their staunch reliance,
And a maze of parts in the realm of arts,
With the gum in each new appliance,
Springs, plates and bars, hubs, spokes and cars,
All bent in an odd alliance,
The refrain take up that, with drinking-cup
Upraised in a Godspeed o'er us,
May be joined by all, both great and small,
Such as never was sung before us,
All claiming free in the fresh new glee,
The thought-brimmed song of the Rubber Tree,
As rich as the anvil chorus!

IV.

Whether vulcanized or elastic, prized
Is the boon of the caoutchouc dearly,
For tools or toys, and for men and boys,
Its use is increasing yearly,
While day by day doth it feel its way
Into workmanship more clearly.
Then hurrah for the juice, so put to use
As to stand in our stead unswerving!
And lend to the song the chorus strong
That will add to its zest deserving—
The song of today and of days to be,
The song so free of the Rubber Tree,
The life of our Era nerving!

NATHAN D. URNER.

—*Indiarubber and Guttapercha Journal.*

* Jamaica is 17° from the equator; that is one difference in its favour as against Ceylon, but the great favouring agent is probably the rich volcanic soil, able to support good grasses in the western colony.—ED.

RICHEST MAN IN THE WORLD.—The *Times-Democrat* of New Orleans has the following statement:—"Sebastião Moreno, is owner of no fewer than seven diamond mines and thirty-five coffee and cochineal estates in Santa Barbara, in Brazil, and undoubtedly he is the richest man in the world. His fortune is estimated at 3,200,000 contos of reis," that is to say £320,000,000. This seems inconceivable, and if true knocks the Rothschilds into a cocked hat. I will not inquire as to the authority of your North American contemporary for this statement, which I find reproduced in the columns of the *Folha Nova* of Rio de Janeiro. Where does Don Sebastião Moreno keep his banking accounts?—*South American Journal.*

FIBRES.—Inventors have now an opportunity of gaining a grand prize. The Mexican Government, I understand, have just offered a prize of £4,000 to the inventor of a machine which shall successfully extract the fibre from henquin, under the following conditions: It must be automatic, and not require skilled and experienced workmen to manage it; it must be entirely free from danger to the operators; it must require less motive force than the machine now in use with relation to its producing power; it must increase the production or extraction of the fibre within a given time, diminishing its loss compared with the various machines in use. The reward is to remain open for three years, and is without prejudice to the right of proprietorship and of patent.—*South American Journal.*

CINCHONA AS A NEW PRODUCT IN MAURITIUS.—At a meeting of the Council of Government of the Sugar sale, the Hon. H. Adam rose to move "that a Special Committee be appointed to enquire into and report upon the best means of encouraging the cultivation of cinchona trees in this island." The hon. member had noticed with pleasure that at recent meetings, similar motions had been announced with respect to the cultivation of silk, tea and tobacco It was acknowledged that the colony was passing through a crisis, and that much consequent destitution had been the result. Some parts of the island had been abandoned for sugarcane planting, and nothing had been planted to replace the sugarcane. He thought that a great part of this land might be turned to account, and that the production of cinchona would be of great benefit to the colony. The gardens at Curepipe had been created almost expressly for that purpose, but the supply would scarcely suffice for the population. He thought his motion would be likely to give good results generally, if it could be extended to the cultivation of tea, silk, tobacco and coffee. The Hon. the Colonial Secretary seconded the motion which was unanimously adopted.—*Mercantile Record and Commercial Gazette.*

TRINIDAD.—While on a visit to Sir Joseph Needham at Trinidad, an excellent opportunity was afforded to see the working of a large plantation in which the orange, lemon, shaddock, pomelo, and every description of citron were cultivated, and in a smaller degree coffee and sugar. The beauties of Sir Joseph's garden, and the kindness and hospitality of the reception, says Lady Brassey, it would be vain to attempt to describe. He had prepared every possible delicacy for every variety of taste. There were tea, coffee, cocoa, wine, cold meats, fruits of every kind, besides orangeade, lemonade, and lime-juice, which the old negro servants hospitably pressed upon us. Those who have never tasted orangeade or lemonade as made in the West Indies can have little idea what such compounds in their perfection are like. They would be appreciated anywhere, but between the heat of the day and the thirst engendered by our long drive they appeared to us simply ambrosial. At the Government House, Trinidad, Lady Brassey and party appear to have had a very hearty reception. Nobody [says the authoress] could have received us more kindly than Sir Sandford Freeling and his daughter Miss Freeling. . . . We had a pleasant dinner in a charmingly airy room—far cooler than many a London dining room in summer. The drawing room was equally spacious and pleasant. Except at the Straits Settlements (Singapore), I have never seen a finer Government House, nor one so well arranged in every respect.—*Lady Brassey's new book.*

The Travancore Estates and Produce Company Limited.—A new company, with the above title, has recently been registered. It is formed to purchase, rent, or lease land in India for the cultivation of tea, coffee, cinchona, spices, and other produce thereon, and manufacture, export, and sell such produce, &c. Registered by Arthur B. Urmston, solicitor, 26, Theobald's Road, Gray's Inn, W. C. Capital £25,000, divided into 2,500 shares of £10 each. The first subscribers are:—Stanley Napier Raikes, J. P., Hill Ash, Dymock, Gloucestershire, 1 share; Robert Napier Raikes, general, 24, St. Edmund's Terrace, Regent's Park, 1; Horace Sibbald Harrison, captain, Torre, Torquay, Devon, 1; William Alves Raikes, harrister, 12, King's Bench Walk, Temple, E. C., 1; Alan Lambert, merchant, 9, St. Helen's Place, London, 1; Ernest Lusmoore Marshall, merchant, 9, St. Helen's Place, London, 1; John Alexander Hanham, merchant, 9, St. Helen's Place, London, 1 share. Number of directors to be not less than three nor more than seven; qualification 50 shares. The first directors to be Major Stanley Napier Raikes, Captain Horace and S. Harrison, and William Alves Raikes. Remuneration, £300 per annum.—*H. and C. Mail*, Jan. 23rd.

Tea Planting Notes.—The following remarks by an able Indian planter on the questions of labour and pruning in India and Ceylon will, no doubt, be of interest to our readers:—The numbers of coolies required in Ceylon for cultivation purposes is less than half what we required in Assam or Darjeeling. We had a visit lately from a Ceylon planter, a very nice fellow, he was astonished at the quantity of, what he called jungle, he saw on our gardens though the said jungle was merely a crop of weeds a few inches high springing up after a recent hoeing. He said that all through the year not a single weed was to be seen on the Ceylon estates. The tea there is all on old coffee estates, many years old. In planting out these coffee estates the jungle and weeds were rooted out and cleared away, and entirely killed out at the beginning and never allowed to get ahead again, consequently very little jungle grows now and the few weeds that do spring up are easily rooted up before they are au inch high. One man keeps 8 or 10 acres perfectly clean all the year round. The yield of tea per acre there is also larger than at Darjeeling, and I believe there is a great future for tea at Ceylon. The only question is, will it die out and cease to yield in time, as the coffee has done? As to pruning, there is no rule as to any particular height a tea bush ought to be kept at. It all depends on the jât of plant, and the original height and size of the bush before the pruning. But it is useless waste of growth letting bushes run away to 5 and 6 feet high of new wood in one season. Hybrid bushes, I should say, are best at about 2½ to 3 feet high after pruning, about 3 in. of this being new wood of the season's growth. In Sylhet I used to do as follows:—Prune bushes flat, leaving not more than about 3 in. of new growth, or brown wood. In plucking, up to the end of April grow five leaves and bud, and pluck two leaves and the bud, leaving three full leaves on the shoot. From May to end of June, grow four leaves and bud and pluck two and the bud. From July to end of August, grow three to four leaves and bud, pluck two to three leaves and bud, leaving one to two full leaves on shoot. From September to end of season, grow two to three leaves and bud and pluck all "Bangy" or open leaf; shoots, in the beginning of the season, will not run to five leaves, but open out and stop at two or three leaves for a long time. These ought to be plucked (say two out of the three leaves) and they will then sooner throw out proper long shoots. Of course, the above is no hard and fast rule, and depends sometimes on the season, rainfall or growth you may or may not be making. By plucking as above I used to get a good crop off the garden and yet have lots of fine growth to prune on by the end of the season. After every five or six years, I think all tea bushes require heavy pruning, *i.e.*, cutting down to within a foot or so of the ground, but leaving the outer or side branches as much as possible, so as not to reduce the bush laterally. After heavy pruning you should let bushes run to six or seven leaves before plucking. Then, at end of the season, don't leave all the long new growth that will have been made on the bush, but cut it down also to about three inches long. These three inches will be enough, and will throw out lateral branches, and so form a good surface of plucking shoots by the second season. I have taken some trouble to study these operations. I have read up all I could find on the subjects, and whenever I got a chance, I used to question good practical men, or men that I knew were really good authorities on the subject and who were also successful planters, so, by keeping my eyes and ears open, I have got to know a little about these matters.—*Home and Colonial Mail.*

Coonoor Coffee Crops.—Picking this season is unusually late, owing, as I said in a former communication, to the failure of the rains and a consequent late blossom. But, at present, great activity prevails, and the fast ripening berry is being picked with an earnestness and avidity truly characteristic of the industry. On some estates picking is already over and the process of pulping and drying are being carried on in view to the despatch of the crop to the coast agents. It is gratifying to hear that the majority of planters have been agreeably suprized in their expectation of the out-turn in crops. In the vicinity of Coonoor the largest producing properties are the "Hill Grove," "Runnymede," "Benhope," and "Meejee" Estates, the crops from all of which have quite fulfilled the expectations of their respective proprietors. The only thing necessary of course to a return of the good old days, being an improvement in the home market. The great importance which coffee has steadily attained to as a staple of commerce very naturally suggests to ordinary thinkers the inquiry as to the best means of still further promoting its culture. Opinion is unanimous to the effect that nothing *can* supersede coffee as a beverage, and though other staples may for a time provo more remunerative as an industry, it goes without saying that coffee cultivation must and will hold its place as an industry, despite losses and failures.—*Planters' Review.*

Planting in the West Indies.—At the recent half-yearly meeting of the Colonial Bank the Chairman, Mr. H. H. Dobree, said that there had been a number of most desponding—and, as he thought, over-desponding—letters from the proprietors in the West Indies and other sugar-producing colonies, stating that the cultivation of cane sugar could never be carried on again at a profit; and those letters had naturally frightened persons as to the future of the Bank. As regarded its future, however, he would say that the West Indies had passed through, and had recovered from, quite as severe a crisis as they were now passing through, and they had been fairly prosperous, at least, for the last 15 years. The present great fall in the price of sugar was in the main caused by the unduly fostered production of beet—fostered unduly by bounties—and to such an extent had that production been encouraged, that the sugar had been forced down owing to the enormous amount which had been produced beyond what the consumer could take, to as low as £10 per ton. That price was stated, by those who were fully competent to judge of the question, to be £5 a ton below the price for which sugar could be produced in any part of the world and under the most favourable circumstances. That was a state of things which could not last long. It was impossible that such an article as sugar could long be produced below its cost. The beet interest was suffering quite as much as, if not more than, the cane sugar interest. In the cane sugar interest, especially in the West Indies, there was every prospect of a reciprocity treaty being concluded with the United States, which would enable the States to absorb the whole of the crops of the West Indies, and, he had no doubt, would be of immense advantage to the West Indies generally. It was believed by gentlemen who had some experience of the management of sugar estates, that although possibly in some of the smaller West India islands cane might go out of cultivation, yet sugar could be produced as cheap, or even cheaper, in Demerara, Trinidad, and Barbadoes as in any part of the world. Another matter of some importance to them was that the West Indies were not so entirely dependent upon the produce of the sugar cane as they were some ten years ago. Of course it was their great staple product, but there was a very large production of cocoa, coffee, spices, and fruit—the trade now springing up in fruit with the United States was very large indeed—and this all tended to make the West Indies to some extent independent of sugar.

HOLMES' BOTANICAL NOTE BOOK, which will be found advertized in another column, is a work worthy of its author, whose name is well-known to readers of the *Tropical Agriculturist*. It is intended as an aid to students in acquiring a practical knowledge of botany, and is admirably adapted for that purpose. First there are diagrams of flowering plants, which are explained, then directions for examining plants, followed by remarks on the microscopical examination of plants and directions for describing plants in the schedules; then comes a glossary, interleaved with blank pages, and then the schedules, which occupy the main part of the book and have an index; after these come several charts with directions and appendixes, a floral calendar, and an index for use in medical schools. All lovers of plants and flowers should have a copy.

HORREKELLY COCONUT CULTIVATION COY., CEYLON.—1. The Directors have the pleasure of submitting herewith the Accounts for the year 1884, shewing a profit of R31,972·63, which, with the balance from 1883, less a loss of R423·48, incurred by the suspension of the Oriental Bank Corporation, leaves a sum of R33,700·57 available for distribution.

2. The Directors recommend that a dividend of 12½ per cent. be paid from this amount on the Capital now ranking for dividend, leaving a balance of R220·57 to be carried to 1885 from the beginning of which year, it may be well to remind Shareholders,—the whole of the Capital of the Company ranks for dividend.

3. The past crop has been a fairly good one but prices have not been so favorable as was anticipated, both Coir and Copperah having for a time fallen to very low figures.

4. The working of the past two seasons compares as follows—(excluding interest):

	1883.	1884.
Expenditure on estate and in Colombo office...	R37,203·89 ...	37,805·77
Quantity of Copperah produced	Candies 1,043 ...	914
„ Coir Fibre made...Cwts.	6,033 ...	6,369

AT THE THIRD ANNUAL GENERAL MEETING of the shareholders of the Tambracherry Estates Company, (Limited), the Chairman, in moving the adoption of the report, said that the past year's working had been very unfavourable, circumstances having combined to make the year an exceptionally bad one. Their crop had been below the estimate, the quality of the coffee had been inferior, and they had had to sell it in a much lower market than had been known for many years. Although the average price per ton for coffee during the last seven years had been £76 per ton, the annual price had gradually fallen off. This he attributed to cycles of bad years following good on account of overplanting. But he looked to more prosperous times ere long. The Company had purchased three new estates in close proximity to their Wynaad property, from which he believed they would considerably benefit. The directors looked for an improvement in the present crop. They had already received advices that 750 tons of coffee were coming forward, from which, if sold at 70s. per cwt.—which was 6s. below the average of the last seven years—they would make a small profit; and even if they could only obtain 60s. they would clear their expenses. They were progressing very favourably with the cultivation of cinchona, from which they hoped to derive a considerable profit. During the past year they had planted out no fewer than 300,000 trees, the monsoon having been most favourable to them; and, according to their last census, they had a total of 727,000 trees growing. The Board intended to continue planting out cinchona until they had 1,000,000 trees growing. If the programme of the board were carried out, they would have over 1,500 acres in coffee in 1886, and 1,000,000 cinchona trees. If they had anything like an ordinary market they would have some young coffee now coming on, which would range from 200 to 230 tons, according to the seasons. The object of the board was to pay their expenses entirely out of the coffee, and to fall back for a bonus upon their cinchona. The directors had on several occasions seriously considered what they should do in regard to tea. He was favourable to some operations, and he believed it could be successfully grown on their estates; but then there was the question of finding labour, and that would be very difficult. For three or four months of the year there would be hardly any labour to be obtained, and that would render the successful cultivation of tea very difficult, if not impossible. But there was another reason why they had decided not at present to cultivate tea even if it were more promising than it was, and that was, the directors were very reluctant to risk the capital of the company in too many undertakings. They had a good thing before them in cinchona, and they saw their way to working up coffee to a paying point. The chairman then went at some length into the operations of the company in the cultivation of fibre, and also the prospects of mining operations in the Wynaad district.—*Home & Colonial Mail.*

THE SUGAR MARKET.—Altbogh we do not in Ceylon grow any sugar (except palmyra jaggery for export) yet the main facts connected with this great and valuable article of food, for such it is, whether used to sweeten puddings, fruit, coffee or tea, cannot but be interesting to our readers. We therefore take a couple of extracts from Patry & Pasteur's comprehensive annual review:—

Notwithstanding all that is said about the cost of production we incline to the opinion that sugar can be grown at a much lower price than was thought possible a year ago; manufacturers and planters will have to be satisfied with a small percentage of profit instead of the splendid outturns of previous years, and every effort will be made to reduce the cost first by improved machinery and careful planting. The American home consumption is rapidly extending, the increase over 1883 being estimated at 150,000 tons. The *Java* crop of 1884-5 will probably prove greatly in excess of any previous one, approaching 490,000 tons. The system of advancing for and buying up entire crops has led to serious financial complications, but even at existing low prices it is reported that the production will not be materially affected. The *Cuba* crop is estimated at about 700,000 tons. *Porto Rico* will have a full crop, probably 70,000 tons, the only important reduction being in the *Brazils*, which had a very large crop in 1883. The *Mauritius* crop has now almost ceased to come to Europe. As regards the Eastern supply, *Jaggery* will only come forward slowly, and in reduced quantity unless prices advance a little; the same applies to *Bengal*, *Penang* and *Manilla*. The *Phillipine Islands* are, however, making a large crop, which will have to be marketed ultimately. The present supply afloat from these countries for Europe and America is 35,000 tons smaller than a year ago. The total visible supply in stock and afloat for Europe and America remains, however, some 200,000 tons in excess of last year's, viz., 894,000 tons, against 698,000 tons at the close of 1883, and 626,000 tons the year before. Messrs. Wm. Connal & Co. estimate the consumption per head of the population in various countries as follows:—"United Kingdom 67½ lb., United States 51 lb., France 26 lb., Germany 12 lb., Austria 10 lb. Russia 9 lb." The figures for Holland and Belgium are not given, but are probably not much behind the consumption of France. They show at a glance the enormous expansion in the consumption of England and America under the influence of complete free trade or moderate duties, whereas the beet producing countries are making but little progress under the existing legislation, which has not only fostered a most artificial over-production, but is at the same time preventing the lower classes from reaping the advantages of cheap sugar as an article of food. A moderate but gradual reduction of duties in Europe would be a better solution for the present crisis than any combination to keep down production, and would at the same time benefit the exchequer of the various countries, which are now paying away in bounties the greater part of the revenue derived from manufacturing.

Fancy Germany giving bounties on sugar, while her poor inhabitants consume only 12 lb. per head, or 3 lb. more than the average in semi-savage Russia. It is not the German people, but the inhabitants of Britain who benefit by the bounties, however much English-growers of cane may be injured by a system which is as foolish as it is wicked.

THE POSITION AND PROSPECTS OF CEYLON TEA are thus noticed in a letter received by us from an eminent London firm :—"The strides made by the Ceylon Tea Industry are very gratifying, and, if your planters can maintain their present high standard of quality, they ought to be able to gain ground rapidly both on India and China, what with the climate of Ceylon, plentiful labour, ready access to shipping ports and comparative nearness to Europe."

CEYLON AND ITS TEA INDUSTRY.—Mr. Arthur Thompson (of Messrs. W. H. & J. Thompson of Mincing Lane) who recently visited the island is good enough to write by this mail to us :—"Having seen several interested in the island I am glad to say that on the whole they seem more hopeful in the general outlook than was the case some six months ago. Of course their mainstay is tea, and in this view, after having seen even the little I have, I can fully concede—given 'good management and care' from the first operation, say the selection of seed, down to the final firing and packing. On these heads they should feel pretty safe judging from the good cultivation that is shown almost universally through each district. So that, if in a few years I am able to return for another visit, I shall hope to see Ceylon sending several millions lb. of tea leaving a satisfactory result to all concerned and making up to some extent for the disastrous results of coffee."

THE PLANTING SEASON IN CEYLON.—The news from the Planting Districts is of weather entirely favourable to coffee blossoms and crops, but far too dry for tea flushing in several districts. It would look indeed as if we were in for another dry season, although, of course, it is too early to say so yet. Some natives however allege that we are in for a dry cycle of years, their coconut crops having fallen off considerably this season and last, for want of the usual amount of rainfall. At the same time over a large extent of our planting country a large abatement in a rainfall rising to 150 and 200 inches may be discounted without detriment to tea, although of course very much depends on the distribution. Whatever be the weather, it is reassuring to know that so many of our planters are able to derive benefit from it. Nowadays all is not dependent on coffee-blossom ; but one may hear : "this weather is bad for my tea, but it will give me some more coffee crop ; or it is good for the cacao or the cardamoms ;" while cinchona is pretty well independent of all weather. In this connection it is interesting to know that Liberian Coffee is by no means a failure in every case in Ceylon although its further planting has been stopped. On one carefully cultivated plantation of 200 acres the crops have been equal to 3 and 4 cwt. of clean coffee per acre for two or three years, and as much as 5 cwt. per acre is promised this season. One of the most flourishing experiences of cacao cultivation is in Western Doloshage under Mr. Drummond's care, showing that, where the soil is good, a very liberal rainfall is an advantage. The cacao there has scarcely suffered from any of the evils complained of elsewhere. It is satisfactory to learn that after a a thorough inspection of a good many districts of the island, so good a planter and shrewd an observer as Mr. Wm. Rollo is well satisfied with the prospects of the Colony especially from tea cultivation. At the same time, Mr. Rollo is one among not a few proprietors who even all through the late years of depression and leaf-disease have made their plantations in Ceylon pay their way and a good deal more—indeed old places in Doloshage have been doing fairly well while now under tea they promise to take a new lease of a paying existence. Careful economic working of plantations which were opened at a moderate expenditure and with no heavy capital loans to provide for has generally give satisfactory results even in the darkest years in this Colony.

KABALMARA (ALBIZZIA STIPULATA).—A correspondent writes from Kadugaunawa :—"Will you kindly procure me, through your columns, identification of enclosed branch ? Is it or is it not *kabalmara gaha?* The Sinhalese are very conflicting in their statements. If it be *kabalmara,* it will require watching when upgrown, as the specimen from which this branch is taken is greatly encumbered with dead wood around the foot of the tree, and, on examining stump-ends of these shed branches, I find them bored through and through in such a manner that the least wind topples them over. There is good seed on the tree yet; if I can obtain assurance of its identity." The specimen is that of *Albizzia stipulata,* and the *kabalmara.* The branches of other species are also very brittle and liable to be blown down during high winds.

NEGRO HORTICULTURE IN DEMERARA is thus described by the Rev. Ignatius Scoles in "Sketches of African Life in British Guiana" :—

Pumpkin creepers may be seen struggling all about, bearing at intervals their heavy fruit, and climbing up bush or broken branches placed there to dry the clothes upon. A few sugar-canes may group themselves in some odd corner, nodding to the wind, and temptiug strange boys to come and taste, and try how sweet they are, for it is the only *cane* that gives them any consolation in their younger days. There, too, the bright green plantain luxuriously flourishes, sending forth with such vigour its long split silken leaves, quite gigantic in their size, waving them in the wind or gracefully bending them at the slightest breeze, while from each succulent stem a huge and heavy bunchs of finger-shaped fruit in profusion hangs. Of tropical plants there are few to compare in general beauty of foliage to the plantain and banana, producing leaves so large and green and yet so delicate and graceful. These two plants, though of the same genus, seem to possess the same specific difference we recognize between the hard winter or baking pear and the soft summer jargonelle. The banana has something of the flavour even of this latter fruit, while the other is rather in taste like a raw potato, and like it cries out loud for cooking. The plantain consequently ranks as a vegetable; the banana as a fruit. The plantain, moreover, is the African's main support, the corn of this country where wheaten corn will not grow. But to return to our garden. Some coconut trees grow there too, leaning all about, or unlike most of the palm-tree tribe, they persistently refuse to grow upright. Where industry is at work many other things can be made easily to grow. For instance, cassava from whence bread and starchare made, yams, purple and white, sweet potatoes all yellow, and no relation whatever to the European, potato, tanias, garden eggs, ochros, black-eye peas, &c.; but the African does not show his industry that way, or make the most of the good things God has given him so unlike in this respect is he to the thrifty Frenchman who turns all things to good account, and as the saying is, will make an excellent soup of a few *stones,* provided you give a little piece of meat and a herb or to flavour them with. To procure, however, some of the more dainty plants for dinner use, or flavour purpose, much trouble is taken and wonderful preparations are made. Every empty box or oilcan, every leaky saucepan, or broken pot, or spoutless jug, or damaged vessel half-hidden and of auspicious origin, is preserved, and one and all they are brought together piled upon boards, and supported by barrels close to the steps filled with well nourished earth, and then planted with the pot-luxuries of African life. There grows the red pepper and yellow pepper, tomatoes, parsley, thyme, celery, and sage tufts of lemon grass for fever purposes, cochineal plants for cooling poultices, aloes and a host of little herbs, as fancy might demand or taste or cookery require. Nor are bright and garden flowers neglected; they too flax their delicate roots in many an empty biscuit box, sardine or salmon tin, and the choice rose-bud or pink is picked from these and placed in David's button-hole when he takes his walk on a Sunday morning, thinking of his soul, or goes on Monday evening to the dignity ball in town, thinking of something else.—*Royal Gazette.*

PLANTING: NOTES FROM HAPUTALE.

14th Feb. 1885.

During the month of January the rainfall did not much exceed two inches on most estates above the Pass. The days were cloudy and misty with occasional light showers, and the sun's heat was not great; but since the beginning of February warmer and drier weather has set in, which is ripening young wood and preparing the coffee bushes for an early blossom. The prospect of crop on all the higher estates continues good, but on most of the lower lying estates along the Koslanda and Lemastota road wind and leaf-disease combined have played sad havoc with the trees, and consequently the prospect of spring crop in that direction is miserable in the extreme: on many places the coffee is stripped of every leaf and the ground is bare as a new clearing, and the bare twigs trying to force out a blossom, but what can the unfortunate trees do without leaves? So the outlook for next year's autumn crop is not very cheering.

While round on that side of the district I had an opportunity of seeing the result of the "patent pruners'" handiwork, the old and long ago exploded idea of cutting back all primary branches to within a few inches of the stem had been done with a vengeance, and the limit of the bearing wood reduced to the smallest circle, all the possible new wood thrown into the centre of the trees making a mass of "crows' nests" of cross wood, making the subsequent handling a difficult and expensive process. Is it any wonder that the crops on these "patent pruned" estates have got "small by degrees and beautifully less," and that the coffee is showing signs of premature extinction? The young men who learnt under this "patent pruner" would do well to get another teacher, or buy copies of Lahorie's and Wm. Sabonadiére's works on coffee planting and study the articles on Pruning. The late high wind along nearly every estate from east to west end of what I will call the Lemastota side of the Pass must have been very severe this year. The coffee is a pitiful sight, wrecked of nearly every leaf on exposed fields, which are just now struggling to throw out a flush of new wood and blossom. Tea may stand these high winds and denuding of leaves, and require less pruning in consequence, but it is fatal to coffee in a few years' time. Tea has been planted out on many estates amongst coffee and cinchona fields, and in small new clearings wherever available, and many acres of tea must now be in the district, but it is difficult to say how much until the coffee and cinchona is removed. Large nurseries and other preparations for extended tea cultivation are visible everywhere, so that our district will soon be giving the new product a fair trial and the question decided of the "yet-unouched-patana" 's capability for tea growing.

Some tea plants put out last year in the Kalupahana valley are growing apace and growing finely, notwithstanding the everlasting wind which proved too much for the coffee and cinchona planted there three years ago. Tea may do there, but the rugged and precipituous nature of the land will ever be a drawback. On Happootella estate I was shown the stump of an old cinchona tree measuring 64 inches in circumference at 18 inches from the ground, which it is intended to send to the Agri-Horticultural Show at Kandy. I mention this as a challenge to other districts to try and beat Haputale if they can with a larger specimen.

J. A.

ANOTHER REMEDY FOR THE PHYLLOXERA is announced. Professor Baner, of San Francisco, has been conducting a number of experiments, and he has, it is stated, found a sure cure in quicksilver. He suggests that half an ounce be thoroughly mixed with an equal weight of clay in the soil of the hole in which the vine is planted. The cost of the mercury was, at the time of the experiment, only ½d per vine, or, as the vineyards are planted in California, from £1 8s to £2 per acre. The suggestion as to the use of mercury came from the fact that a small globule of that metal in a case of mounted butterflies will protect them against the depredations of beetles, and also to the fact that mercurial treatment is destructive to insects. It is believed that a dose of the mixture will protect a vine for at least twenty years. —*European Mail.*

SUGAR IN PERSIA.—A correspondent of the *Times* writing recently from Teheran mentions the strange fact that although the sugar-cane is abundantly cultivated in Persia, there is not yet a single manufactory for producing sugar in the country. Consumers are entirely dependent upon Java, France, and Russia for their supplies of sugar. An encouraging feature is the fact that the Persian silk crop has this year proved most abundant, and it is expected that the Persian silk trade, which has long been depressed owing to the failure of the crops, will now show distinct signs of revival. It is even hoped that the former highly prosperous state of this trade may again be reached. The practical conclusion to which the correspondent desires to draw his readers is that it would be a good thing if the English and Russian Governments could agree to act together in aiding the construction of railways in Persia. The writer does not appear to have any doubt that political difficulties might intervene to prevent the execution of his plan. What he is impressed with is the conviction that in Persia there is a large field for the profitable employment of capital in the construction of railways, and that England and Russia may with advantage join hands in providing the necessary means.—*Home and Colonial Mail.*

THE FORMATION OF LATERITE BY THE OXYDATION OF FERRUGINOUS ROCKS is thus noticed in a paper on the geology and mineralogy of Malacca by the Rev. J. E. Tenison Woods of Australia, who ought to be asked to make a similar report on Ceylon:—

The paleozoic rock is largely mixed with poor iron ores, and where the surface water charged with carbonaceous matter has come into contact with these ores, they have been oxydized and converted into a red and reddish-brown limonite called here laterite. This laterite has been a geological puzzle to most of those who have written on the geology of the Malayan Peninsula. It is remarkable what a variety of guesses have been hazarded as to its origin. Some writers who have pretended to offer an explanation seem purposely to have obscured their meaning from inability to deal with the difficulty. It has been called volcanic, and regarded as a tertiary outpouring of basalt, and so forth. As already stated, the real character of the stone is simply due to the oxydation of a ferruginous series of rocks. The formation which has mostly supplied the materials for the laterite is the stratified paleozoic slates and the granite in contact with them. It is a decomposed rock. Water and air have been the decomposing agents. It is a most significant fact that there is no evidence whatever or recent upheaval from the sea, or even marine action. It would be hardly possible for this laterite or limonite with silicates of iron to be in course of formation without entombing some marine remains had they been in contact with them. Malacca is no exception to the general rule throughout the Malayan Peninsula that there is no evidence of recent upheaval in all the great extent of its coast line.—*Straits Times.*

COCONUT COPPERAH.—The present price of copperah, on which some people are felicitating themselves, we are assured by competent authorities, cannot make good the losses from scanty crops. Even well-cultivated estates have given only about one-fourth their usual outturn at the last two pickings; and prices are bound to rise. The present drought threatens further to lead to short crops for the rest of the year, as young nuts are dropping off freely in most places. One estate, whose highest picking was close on 80,000 nuts, has just picked only 10,000—the corresponding picking last year having been 30,000 nuts. Another which picks 5 to 600,000 nuts has just gathered only 150,000, while a third has fallen from 400,000 to 100,000. These are the results of the rainless months in the first half of last year. The absence of rain since December will be felt, as regards results later on; so that copperah is bound to go up much higher; and unless it does, proprietors must suffer. The weather suitable for coffee blossoming has come too late to help coffee, and is likely to prove injurious to tea up-country, as well as to low-country products.—Ceylon "Examiner."

CEYLON UPCOUNTRY PLANTING REPORT.

IMPROVEMENTS IN JACKSON'S HAND ROLLER AND RESULT—NO BAD TEA TO BE FOUND IN CEYLON!—THE HERO OF THE LEAN HEN AND HIS GIFT TO HIS LADY FRIEND—SIGHING FOR RAIN—FEVER IN MATALE AND DUMBARA—COOLIES PLENTIFUL—SINHALESE LABOR OFFERING—TEA SEED—FINE WEATHER FOR CACAO CURING.

13th February 1885.

I have heard of a considerable improvement which has been made in Jackson's hand-roller by Mr. A. E. Fleming of Bogambara, Kandy. The alterations, which consist in enlarging the box and some other matters, have had the effect of bringing the rolling power of this machine up to 1,700 lb. of green tea per day of 10 hours.

I have before me while I write a report of the working of the improved roller. The work was done on Elkadua estate, and, as the time taken for every charge of the machine has been carefully noted, and is of so much importance to all tea-planters, I enclose a copy of it, so that you may give it the publicity which it deserves :—

Two days' work of the Elkadua tea roller.

Hands.	Quantity of withered leaf.	Commenced filling.	Commenced rolling.	Finished rolling.	Quantity of withered leaf.	Commenced filling.	Commenced rolling.	Finished rolling.
	lb.	a.m.	a.m.	a.m.	lb.	a.m.	a.m.	a.m.
1st	60	6-35	6-40	7-3	60	6-17	6-21	6-42
2nd	60	7-6	7-11	7-33	60	6-46	6-50	6-11
3rd	60	7-36	7-40	8-1	60	7-15	7-20	7-42
4th	60	8-4	8-7	8-27	60	7-47	7-51	8-12
5th	60	8-33	8-37	8-57	60	8-16	8-19	8-39
6th	60	9-1	9-6	9-27	60	8-42	8-46	9-09
7th	60	9-31	9-36	9-56	60	9-13	9-18	9-40
8th	55	10-1	10-5	10-24	60	9-44	9-49	10-12
9th	50	10-27	10-31	10-51	60	10-17	10-21	10-45
10th	50	10-54	10-59	11-20	50	10-49	10-56	11-18

5th Feb.—The 10th hand was emptied out of machine at 11-25 a.m. Time taken to complete 575 lb. withered leaf was 4 hours 50 minutes made tea was 204 lb. The machine is thus capable of rolling off 1,700 lb. green leaf per day of 10 hours.

6th Feb.—The 10th hand was emptied out of machine at 11-22 a.m Time taken to complete the 590 lb. withered leaf was 5 hours 5 minutes; made tea was 215 lb. The machine is thus capable of rolling off 1,700 lb. green leaf per day of 10 hours.

Much credit is certainly due to Mr. Fleming, for so considerably increasing the working power of this machine, without in any way affecting its efficiency; for, besides pulling through such a large quantity of tea, it gives a perfect twist to the leaf. This is but another instance of what I have always maintained, the highly inventive character of Ceylon men. Doubtless, before tea is very much older in this island, we will be hearing of more work of this kind, and the tea-planters of India and elsewhere will have to look to Ceylon for wrinkles on cultivation and improvements in manufacture and machinery.

For a long time back I have been trying to ascertain where I could find a field of bad tea. Only lately I thought I was fairly on the track, and I had a feeling of satisfaction in thinking that now I was to be successful in my quest. Alas! at the last moment it has slipped me. The extent was big enough, 100 acres, the quality, a most inferior jât, but just when about to swoop down on it, and use it as a text for a paragraph in my letter, I was told that I need not trouble, for it is giving the owners flushes as fast as the coolies can pluck them off! We hear so much regarding inferior jât, that it is disappointing that nobody will own up to the possession of ought else than but a few trees, and that this rock ahead of which all are warned can't be located in any of the tea districts of Ceylon. The light that never was on land or sea is the nearest thing that I know of which at all approaches that which everyone talks of and no one has seen—a field of really bad tea in Ceylon. I don't say it does not exist; but I do say that I am weary of enquiring where.

I fancy most people who have read the good story lately told in your columns by "Old Colonist" about the lean hen enjoyed it as well as I did. Saving could hardly go further, and it was only a master of the art who could have conceived such an ingenious plan of gathering up the fragments so that nothing might be lost. I have no doubt in my own mind as to who was the hero of the tale. Great souls like great events only appear now and again in a generation, and, in offering a humble contribution to the biography of this illustrious one I feel I am wronging no brother-planter past or present when I claim for the man, who took his lean hen to market with him so that it might pick up what his horse "skailed," that of being the spokesman in the tale I would tell. A lady friend of his was leaving the country; one who had shown the saving Scot much kindness, executed many a commission, and in a thousand-and-one ways had otherwise been of service. The occasion was a great one, and the great man made a wonderful effort to rise to it—he was going to hang expense and give the lady a present. He arranged with a Bombay trader to meet him at the lady's bungalow, and told her when they arrived how much he was indebted for the kindnesses of the past, and that he desired to show his appreciation by giving her a "wee bit present." The lady protested, no need for such a return or any return at all, she had always been glad to have been of service, and much more to the same effect. Hard-fisted Scot, listening incredulously, could not conceive of a nature which could act so generously, but, quick to avail himself of the turn of affairs, shaking out a China shawl, he said: "Wid na that suit you? kind o' payment as it were." The lady assured him again that there was no need of any payment; so he handed the shawl back to the man, saying in reply: "Weel, weel, ye ken best." "Tamby po!"

Like everyone else we are sighing for rain. Those who have tea holes to cut in this weather know how difficult it is to get anything like the proper size out of the coolies, and how worrying it is to be kept back.

About Matale and Dumbara fever is very bad, as I fancy it is generally in all low places.

Coolies are plentiful, and gangs offering now and again. The Sinhalese, too, are very willing to work in clearings if allowed to go and come as the spirit moves them. They are very poor as a rule, the failure of their little patches of coffee and the adjoining estates from which they were so fond of drawing, having sadly affected their finances.

Orders for tea seed are on favoured estates booked considerably in advance, but the price is not rising, a tendency rather to sell at rates somewhat lower than those advertised.

Fine weather for curing cacao, which ought to keep up the name of the Ceylon marks in the London market.

PEPPERCORN.

CINCHONA LEDGERIANA.

SPLENDID RESULTS IN WYNAAD.

We have to record that from the Chembaly estate at Gudalur, an analysis has been shown to us by the Government Quinologist Mr. David Hooper, of Cinchona *Ledgeriana* natural bark, which is surprizing and exceeds anything

hitherto recorded; it amounts to 11·31, of crystallized sulphate of Quinine. This is reported to be the *average* from twenty-one trees not quite six years old. The next best analysis is that of Mr. Thomas North Christie's celebrated St. Andrew's trees in Ceylon, which at the age of six years were said to average 10·25. These splendid results have been accomplished by private individuals, and our Government in twenty-five years has done nothing except get a batch of inferior seeds over. We understand that Mr. Hamlin the proprietor of the Chembaly estate has a few seeds to spare, and these who really desire a first-class strain of plant should secure them. The Government should also secure some for their experimental plantation under Mr. Lawson at Gudalur.—*South of India Observer.*

DOCK COMPANIES AND TEA DISCOUNTS.

The competition between the Dock Companies resulting in an increase in the discount allowed upon tea, and the consequent reduction in profits is exercising the minds of directors of, and shareholders in, the various dock companies and several letters have appeared in the *Times* on the subject. At the half-yearly meeting of the proprietors of the East and West India Dock Company, held at the Dock House, Billiter Street, E.C. (Mr. H. H. Dobree in the chair), an interesting discussion arose on the subject, respecting which the following paragraph appeared in the report adopted by the meeting:—"The only feature in the business of the past year calling for special notice is the increase in the discount allowed upon tea, which has been forced upon this company in spite of the strenuous opposition of the directors."—*Home and Colonial Mail*, Jan. 23.

"CEYLON AS A FIELD FOR THE INVESTMENT OF CAPITAL AMD ENERGY."

HOW A COFFEE PLANTATION HAS PAID ITS WAY IN A POOR PART OF A HIGH DISTRICT.

You ask me to tell you the story of "How we kept our wattie." I cannot give you full particulars, because, if I did so, my partner might not like it; and a good partner is not to be sacrificed to satisfy the cravings of an inquisitive public.

I think one of the chief elements in our successful attempt to hold our own over a space of 12 years was our being mutually blessed (ahem!) with caution prudent partners who would not contract a debt greater than they could pay off with funds available elsewhere.

A good soil for coffee and a climate suitable for this peculiar tree were not what kept the wolf from our door; for the elevation was over 4,000 feet; the climate decidedly wet, say 180 inches, if not more S. W. exposure; and the plants in nursery were covered with leaf-fungus. I question if there could have been a poorer investment as a coffee estate pure and simple. I don't think we ever averaged more than 2 cwt., and we often tumbled down to ½ a cwt. We did not spend much on buildings. I think bungalow, lines and stores did not cost more than R4,000. We wasted about R6,000 in manure. We roaded and drained the estate very effectively.

Cinchona has done not so badly however; officinalis very poor; but the plain but honest succirubra has certainly done us a good turn.

The superintendence averaged R2,000 per annum for a little over 200 acres—given to others. If we had worked our own property, that would have been an income very few farmers in England or elsewhere would have got out of 200 acres.

To sum up, the estate stands us at £3,000 sterling. We have 80 acres of good cinchona, which, if harvested in the next year, should give us £2,000 worth of bark, and we have this land for tea. We have 110 acres of good land planted with tea from 1 to 3 years old most promising, and about 30 acres of not so bad coffee that will last for two or three years yet, if we do not find tea a more profitable investment. The conclusion I at any rate have come to is that I would not part with the property for £6,000, should any of those Tea Company gentlemen offer "cash down." Why should we? I think we have found the products that will give us paying returns. We were very despondent about 18 months ago. We are now chirpy.

Ceylon property, if the proper product is grown in it and, if judiciously and carefully managed, will hold its own with that of any other country, and what a place it is to be here. A really temperate climate, only three weeks distant from England by P. & O., but will be only that time's distance from the dear old country when the first "ditcher" really does her best. The passage to London and back will soon be R500. I shall be able to harvest my tea and go home and square up with my London agents for four months every year if so disposed.

Ceylon gone? Never a bit! We have a shot in the locker yet, and her Planters have the stuff in them that command success. FLOREAT LANKA.

COFFEE *VS.* TEA PLANTING IN CEYLON.

A WARNING TO YOUNG TEA PLANTERS.

(By Old Colonist.)

The grand old happy-go-lucky planting days of Ceylon are no more!—the days when the gentleman in charge of estates could, with impunity, leave the store kanganies to dispatch crop, and, mounting his *kudiri*, leave the tottam to take care of itself, for days or weeks. This evidently won't, suit tea, and I can well understand how tedious and irksome the life must be to many a good old coffee planter.

I have been led to this reflection by having just superintended the opening of 10 chests Ceylon tea. My attention was first attracted to the tea trickling through the gaping seams of the boxes as they were being landed from the lorry to the pavement. And this is "the tea of the future, is it?" chaffingly said a big wholesale grocer; "I hope it 's better than it looks outside."

The chests are certainly not first-rate specimens of handicraft. It would be difficult to conceive of any village "wadurala" in the wilds of Sabaragamuwa who would not blush to own the work. The doors on a R15 set of lines would look cabinet work beside these rude boxes.

It was all very well for the store kangany to shout: "Kariyam illai, summa kondu po!" as the innocent cooly called attention to the gaping seams, but this sort of thing is apt to crop up again.

The rough exterior is, however, not the worst feature in this case, no attempt at soldering or even over-lapping the lead can be discovered, but a dirty piece of grey paper covers the top, while the huge nails, by which the little bits of hoop are fastened, effectually lacerate the lead around the sides.

The net result of all this is, here I have before me 900 lb. of Ceylon tea, *decidedly musty*. A beautiful leaf, evidently well and carefully prepared, but spoiled for lack of ordinary care in packing. Reduced in value in consequence from 1s 6d to 1s 1d per lb. How differently the Chinese stuff is treated! how carefully any little aroma it ever had is preserved! how neatly the lead is soldered; and with what pains the air is excluded! Papered and painted, the chest is a work of art in itself which it would be in vain to hope the Sinhalese to imitate, but undoubtedly, if Ceylon tea is to get fair play, more care will have to be taken in packing it.

OVERPRODUCTION.

At a recent meeting at St. James's Hall, London, crowded with Radicals, Democrats, Socialists, Land Reformers, *et hoc genus omne*, Mr. Henry George was discussing, as is his wont, the wrongs of the thousands of unemployed in our wealthy cities and the various causes to which, by different authorities, the want of sufficient employment for all is attributed. Among these causes he enumerated Overproduction: "Overproduction," he shouted, "that is, such lots of corn and meat that tens of thousands must needs go hungry."

Now, anyone nursed in the tenets of the older school of political economists from Adam Smith to John Stuart Mill is apt to feel but scanty sympathy with the pronounced teachings of Mr. Henry George. But the above simple paradox can hardly fail to appeal, at least, to the commonsense of all, whatever be their views on political economy, while to hundreds of men of business it runs on all-fours with their daily experience for the last few years. In nearly every trade the position is the same: one hears of abundant supplies, very low prices and general consequent depression. The puzzle is: How can a time of almost universal abundance be really and actually, as nearly all are holding it to be, a bad time? What is the explanation? It lies in a flat contradiction.

It is *not* a bad time; on the contrary, taking the *whole* population of the United Kingdom into account, never was so good a time. While all necessaries of life are abundant and cheap to a degree unknown for many years, wages have fallen by no means in proportion to the fall in prices of commodities; and the result is, that, while among the few millions of capitalists, merchants, farmers, &c., there is the much-complained-of depression, among the many millions of wage-earners there is a steadily, nay, rapidly increasing consumption of all that goes to make life tolerable, if not comfortable. The conclusion is, that never before were the people of the United Kingdom, *taking them all round*, so well off as they have been during the last few years of so-called mercantile depression.

It is true, that, during this year, the fall of prices has been aggravated to such a degree in some branches of trade as to react on the power of giving employment to labour, and it may probably be necessary that wages be now lowered to meet the pressure of low prices. Again in other branches of trade, such as ship-building, there is a reaction from the excessive activity of the last few years. But these are exceptions to the rule, and Mr. Henry George would find it difficult to show, that, taking *all* the working folks of the United Kingdom, there was not a distinct increase of well-being in the aggregate. In favour of our view we have the authority of Mr. John Bright, and still more to the purpose the Poor Law returns which show a very great reduction in the percentage of pauperism to population since 1874, when the fall in prices may be said to have begun.

But we may have some of our readers saying, "What is all this about overproduction and abundant supplies? It is little *we* have to complain of in that way." Alas! no, Ceylon has been a sad exception to the rule of abundant production. But the consideration of the plight of others who have been more fortunate in that respect may well be a warning for the future. The coffee-growers of Brazil, the corn-growers of India and America, the sugar-growers of Europe (with their bounties): how have these fared with their abundant crops? They all find themselves in the same position as the planters of Ceylon, inasmuch as they have to sell their produce at a loss for the benefit of the consumer.

Much has been said in the writings of political economists of the "unearned increment," and it has been the custom to lay down as an axiom that value is ruled by cost of production. It seems to have been overlooked that there may be times when there is a corresponding "decrement" in value, when the cost of production cannot be obtained in any market. At this moment, while Mr. George is declaiming to British workmen as to their lawful share in the unearned increment in the value of the land of England, not a word does he tell them as to how they are enjoying in their bread and sugar the unearned decrement in the value of the products of the labour of thousands in other lands.

The problem then before the planters in Ceylon is so to direct their course that they may not in the future find themselves compelled to hand over the whole fruits of their labours to the consumer. Has anyone tried to realize what would have now been the position of affairs, had all the Cinchona planted come to maturity? It makes one shiver to think of it.

The best chance for the future, lying as it does in tea cultivation, would seem to be summed up with the utmost brevity in the three words:—

QUALITY NOT QUANTITY.

A CRISIS IN THE BRAZIL COFFEE CULTURE.

Mr. John S. Vans Reesema writes to us from South Wynaad:—"While Indian and Ceylon coffee planters have been struggling against low prices and leaf-disease for the last few years, it appears that all is not "*couleur de rose*" in other parts of the world, and that the coffee culture in Brazil is handicapped with even more crushing penalties than those we labour under. The following translation of a cutting sent me speaks for itself, and from other sources I learn that unless some immediate and very sweeping reform takes place in the supply and condition of labor in the Brazil planting districts very large deficiencies in crop will be the result: as much as a million bags within the last two years is stated to be the probable or possible decrease. I need hardly point out how this would affect our market:—

"Mr. Antony Kessler has written an elaborate review, (in the organ of the Indo-Dutch Association of Industry and Agriculture of a report published last year by the Brazilian Professor Conty, on the origin of the present depressed position of the coffee cultivation in that Empire. He condenses the report and the conclusions at which arrives as follows:—

1. That the present position of coffee cultivation in Brazil is very deplorable owing to the high cost and inefficiency of slave labor.

2. That the supply of this expensive but indispensable labor, is even now insufficient, whilst the heavy yearly mortality among the slaves rapidly diminishes the number available.

3. That neither free slaves nor Cabales can be used for the work in the factories, and therefore a supply of other laborers must be obtainable.

4. That the importation of Chinese coolies cannot remedy this, as they are even more expensive than slaves.

5. That only European immigration can avail, and that this is not practicable owing to the social distinctions in the Empire.

All depends at present whether planters can be speedily induced to admit the necessity of such radical changes as according to Dr. Conty, are necessary to induce 500,000 European to settle in Brazil within a comparatively short time. In spite of Dr. Conty's exertions this appears highly improbable. Were it merely a question of developing a new industry it might be easy to attract necessary laborers by offering liberal terms; the extension of new openings would then keep pace with the average immigration; and al-

though planters would be in continous labor difficulties it would be quite possible to work the industry at a profit. But here the case is different. The already very considerable labor deficiency is increasing most rapidly and the immigration of Europeans on which all hope depends is utterly insignificant. The existing coffee estates, in the struggle to maintain their existence will steadily raise the price of labor, until at last it reaches a limit which will make it impossible for most planters to work at a profit, and force them to abandon their estates. In the face of these facts it is a very open question if immigration will rapidly increase. The conditions of life by which immigrants would find themselves surrounded are not altogether attractive and although this has been recognized for years, the Government still continue to maintain laws subversive of all liberty of action, and which deter possible cultivators from settling in Brazil. If these drawbacks, which might be removed with comparative ease, continue to exist by general consent it is scarcely probable that the radical changes in the whole system of land tenure as advocated by Dr. Conty's will be effected.

If the Brazil landholders sold their land in small blocks they might possibly as the writer of the report suggests realize large fortunes, but it is easy to foresee that a mere buying and curing of crops would not yield large profits. The curing of coffee is not such an intricate operation that the small producers would find it impossible to perform it for themselves, and it is certain that they would sooner send the article into the market ready for consumption than employ a curer and planter as a middle man they could as well do without. All these difficulties, which we may accept as being in existence although they are not specially mentioned in Dr. Conty's report, will postpone for a considerable time the realization of his radical plans, and if this realization is a *sine qua non* for the continuance of coffee cultivation in Brazil as represented on the report, there can be no doubt that the industry is passing through a most dangerous crisis which must ruin numbers of estates before it can be solved in a satisfactory manner."

Thus far the translation. Although what the German call *ehaden freude* is not a very exalted virtue, it would be to expect too much of human nature if the foregoing were not looked upon by coffee planters in India as good news. There is no doubt that we shall as much benefit by the misfortunes of Brazil, as we were damaged by her enormous crops; and if the conjectures of the report are correct there is a good time coming for us.—*Madras Mail.*

INDIAN TEA IN TIBET.—The Shanghai papers, alluding to Mr. Macaulay's attempt to establish a trade connexion between India and Tibet, express the belief that the Indian gardens can supply Tibet with teas of ordinary quality at a cheaper rate than China, both because the journey is shorter, and because the Indian article is better at the price.—*Pioneer.*

WATER-POWER AND THE ELECTRIC LIGHT.—We have frequently drawn attention to the utilization of the large amount of water-power on Ceylon estates for the generation of electric light. Bungalows might so be lighted, and tea-houses, where occasionally night work must be done. At the annual meeting of the Society of Arts, the Chairman, Sir F. Abel, said:—

An illustration of the application of water-power to the working of an electric light installation, of about the same magnitude as that which Mr. Preece has established, has recently come under my notice, of which a sligh outline may be interesting. A small stream, a feeder of the Teviot, runs through the grounds of an estate near Hawick, and advantage has been taken of it to obtain the power required to illuminate the house and adjoining stables. A turbine has been erected at 350 yards distance from the house, capable of furnishing about 8 horse-power, and requiring 270 cubic feet of water per unit when working at full power. As the stream does not furnish nearly the required amount in dry weather, a reservoir, in the shape of a lake about an acre in extent, has been constructed in the path of the rivulet; and as the latter furnishes at least 80 cubic feet per minute in the driest weather, the storing of the water during the daytime in dry weather furnishes more than sufficient power to work the turbine when the lights are required. The turbine, housed in a small building, is connected with a Siemens compound self-regulating dynamo machine, capable of working about 70 Swan glow lamps of 16-candle power. About 80 lamps, a few of which are 32-candle power, are fitted up altogether in the house and stables adjoining, and in the avenue leading to the lodge, which is 400 yards from the main building; the latter are controlled by a switch near the hall door, so that they may be lighted up when required. For stopping the turbine at night, a sluice-valve can be closed from the house by means of a simple electrical arrangement. The whole instalation is stated to be a good specimen of the class of work which might be carried out at many country houses, where there is a sufficient supply of water-power within convenient tance.—*Journal fo the Society of Arts.*

GUTTA TRAP.—Gutta Trap is a substance evidently allied to guttapercha and caoutchouc, employed in Singapore in the manufacture of bird-lime. It is the inspissated juice of an artocarpus, and it is highly probable that there are several similar vegetable productions, such as the mangegatu (*Ficus indica*), from Visagapatam, which might be introduced into commerce, and employed in the arts for purposes similar to those for which caoutchouc and guttapercha are now so extensively employed.—*Indiarubber and Guttapercha Journal.*

Der Kaffee in seinen Beziehungen zum Leben (Coffee, in its relations to Life). By Dr. Heinrich Boehnke-Reich. Leipzig; F. Theil. This is a book written to celebrate the two-hundredth anniversary of the introduction of coffee into Austria and Germany. With a great deal of industry the author has collected all that is interesting concerning the history, the chemistry, the botany, the medicinal value, and the dietetic nature of coffee, together with much information regarding its commerce, the substitutes and combinations which it has called forth, and the various methods of preparing it as a beverage. Readers of German will find all this presented in a pleasant style. The facts given concerning England seem to indicate accuracy and wide information. For example, the details of the seizure of the Conroy malt coffee on the part of the Excise and the subsequent modification of the law affectign coffee-mixtures are related with exactitude.—*Chemist and Druggist.*

AGRICULTURE: HINTS TO THE D. P. INSTRUCTION, CEYLON.—As regards the literature of agriculture, the past year has not been barren. Several valuable lectures were delivered at the Educational Conference in connection with the Health Exhibition, of which we would specially call the reader's attention to that on the higher branches of agricultural education by the Rev. J. McClellan, Principal of R. A. College, Cirencester; and one on "School Farms," by Mr. H. M. Jenkins, who advocates that to each of the middle-class schools a small farm should be attached, and that instruction in practical agriculture should be included in the ordinary curriculum. It is suggested that the farming capital necessary could be raised by subcription, and the Education Department should give building grants at least as liberal as these hitherto art. given towards the construction of schools of science and Further than this, Mr. Jenkins suggests that in each county a suitable farm should be found, whose proprietor is willing to receive appreutices for a term of years; these might thus be thoroughly trained in practical work, and such training would be invaluable as preliminary to occupying a bailiff's place. The want of well-trained and educated bailiffs is a most serious obstacle to the profitable occupation of land by an owner. If school farms are formed, then Mr. Jenkins considers that the Educational Department should give to their most successful students free scholarships, either for the Normal School of Science, or the R. A. C. at Cirencester, or the College of Agriculture at Downton. Also, that the school farms might be recruited by scholarships being given to the most successful apprentices at the farm schools. Good steady work is being done by the Educational Department, and agriculture is taught in an increasing number of elementary schools, whilst here and there itinerant lecturers are collecting good classes from amongst the sons of farmers, schoolmasters, &c.—*Field.*

COCONUTS (COCUS NUCIFERA).

FROM A PAPER BY J. H. WRIGHT.

Mr. President, Members of the Bayonne (Florida) Scientific Circle and Visiting Friends:

Having the honor of reading to this association another paper upon "Tropical Fruits," I have selected as a subject for our evening's talk "The Coconut Palm of the Tropics," a tree so sensitive to the slightest frost that it will not mature with any degree of certainty north of the 27th degree of latitude, and bearing a fruit with a shell so hard, that it would lead one to suppose it was easily cared for and required but little attention. On the contrary, it is one of the most delicate fruits the northern merchant has to handle, for when removed from its outer husk, it will crack when allowed to fall but a few feet, or when exposed to the sun, wind or frost, will split open, letting the air to the meat, causing rapid decay.

The true and original home of the coconut is India and the South Sea Islands, but distributed by the aid of man, as well as being cast upon foreign shores by the ocean waves, where they have taken root and flourished, it has become a prominent feature in almost every tropical land on the face of the globe.

The coconut coming into our northern markets simply as a luxury, its real value to the human race is but little understood. Its forms almost the entire sustenance of many uncivilized races of the tropics, who use every portion of the tree and nut. From the tree they build their rude huts, with the leaves thatch their houses, from the meat obtain their food and oil, from the husk make their garments, also twist from the fibre their ropes, cordage, &c. From its juices they distil liquors and make their medicine, and carve from the shells not only their household utensils but all manner of ornamental trinkets, the shell being susceptible of a very high polish. Even the leaves were used by the ancient Buddhists to write their manuscript on.

A gentleman relating his experience among the South Sea Islands, said of the inhabitants that they had fewer wants, fewer natural resources, and fewer ties of relationship to the rest of the world than any other human beings, having no necessities that cannot be supplied from a single source—the "coconut tree"—which gives him his food, drink, oil and shelter, his scanty dress, canoe, sails, nets and cordage implements and utensils of various sorts. His native land—nothing but a narrow strip of coral sand swept together by the waves into a coral reef—all consists of a single material, the carbonate of lime. He knows no ground higher than his sandy beach, having never seen a mountain or a river, and living entirely without fresh water, except that which he obtains from the coconut, his coconut diet being varied only by an occasional fish or bird. He can make his fire by friction, but has little use for it, for in the absence of material for his dinner, a good nap in the sand on the beach furnishes a refreshing substitute. He has no tillable ground and no agriculture, and little occupation other than fishing, bathing and gathering coconuts. He has but little knowledge of any other people than the two or three hundred of his own kind, with whom he has grown up. A language of a few hundred words has sufficient capacity for his needs of expression. He has no neighbours, no foreign intercourse, no trade or traffic. He is surrounded by sea and sky, and knows nothing beyond his own horizon.

PRODUCTION IN FLORIDA.

The question is often asked—Will coconuts grow in any portion of the United States? In reply I would say that such a small portion of our country is either tropic or semi-tropic that coconut raising in the United States will never command much attention, although for many years coconuts have grown in southern Florida, but owing to an extreme fondness for the green nut, manifested by those engaged in the sponge fishery along the coast, but few nuts have been allowed to ripen, only sufficient to demostrate the fact that coconuts can be raised for several hundred miles along the coast, where the Gulf Stream (that great distributor of tropical warmth), flows so close to its shore. The coconut industry in that vicinity has received a fresh impetus of late, for several northern capitalists have gone to Florida and embarked in this industry, seeing (like Col. Sellers), "millions in it." Last season over one hundred thousand nuts were planted in one district of a thousand acres, and it is expected that number will be largely increased the coming season, so that in a few years we may see in our own northern market "Florida coconuts," thus developing a new industry for the South that may add one more to the many yet undeveloped resources that industry, energy and capital will bring to light in that portion of our country so favored with perpetual spring.

PLANTING AND CULTIVATION.

In the tropics, where the coconut is wanted for planting, the nuts are picked up from the ground as they fall from the tree, where they have hung for about fourteen months in ripening; and it is a fact not generally known or noted that a majority of the nuts drop at night, which probably accounts for the small loss of life by coconuts falling upon the heads of the natives. One reason given for singular freak of nature is that the action of the heavy dews at night, so noticeable in the tropics, loosens the seal nature has provided it with, and allows it to fall. Such nuts as are wanted for planting are either gathered into heaps or placed under sheds, where they are allowed to remain until the sprout shows itself through the husk. The principal reason assigned for selecting this mode of allowing the nut to sprout before planting is that good, healthy sprout nuts may be selected, thus avoiding the possibility of planting "blind" nuts that would not sprout, in which case much time would be lost in starting the "Coconut Walks" (as their orchards are called). When planted in this manner much care is excercised in selecting and handling the sprouted nuts, to see that nothing but strong, healthy nuts be planted, also to see that the sprouts are intact, for by planting a weak, unhealthy nut, or one whose sprouts are injured by rough handling, a tree of poor growth and late bearing grows. When planted in regular order holes are dug about three feet deep and from fifteen to thirty feet apart; in the hole the nut is placed with care, covering it with about one foot of soil, continuing to fill the hole as the sprout grows, until its reaches the surface, when it is left to itself, requiring no further attention. Should the place where the coconut is planted be any great distance from the seashore a quantity of salt is placed in the hole, and sometimes scraps of old iron, as, it being strictly a salt water-loving tree, it will thrive but a short distance from the shore; nearness to salt water being absolutely essential to its welfare. As an interesting evidence of the above, I will cite an instance of a tree that was planted behind a board fence some distance from the sea. Mr. Goodwin, of the firm of Goodwin & Sturges, of New York, importers of West India fruits, related to me his experience in watching the growth of this tree in his yard in Brazil. The tree grew perfectly straight until it reached the top of the fence when it began to lean or grow toward the ocean a foot or more, when a shed was built quite near the fence, several feet higher, and the tree assumed an upward tendency and grew straight until the roof of the shed was reached, when it again reached out toward the sea, forming a very curious and odd-looking tree, which he wholly attributed to the influence of the salt air. In fact no magnet is truer to the pole than is the root of the coconut tree to the ocean, for when the root breaks through its husk it points direct toward the sea, no matter in what position the nut is placed in the ground. Boring its way downward it fastens itself so deep and firmly in the ground that no tornado, no matter how severe, has ever been known to wrench it from its moorings, but the hurricane, so frequent in the tropics, will often twist the trunks in two and carry the broken portions a long distance, thus ending the coconut palm, as it will not sprout a second time.

Could you examine a coconut when in the process sprouting you would find directly beneath the sprouting eye a small white mushroom-shaped kernel, and in this little germ lies the life of the future tree. Shut up in its prison-like shell—and the shell, surrounded by many inches thick of tough and tangled fibre, how is it to work its way out and perform the duty assigned it? for it is apparently as soft and tender as a baby's hand. Soon its tiny fingers begin boring their way out of the weakest eye, then, reeding the tough, woody fibre right and left, it forces its tiny fingers to the surface and commences the campaign of life, sending its shoots upward to form the tree and

downward to form the roots, still clinging to its parent for its support until the entire inside of the shell is filled with a round, white, ball-like substance that is formed by the congealed milk of the coconut. From it the roots, fast forming, receive their staff of life, until the mother "coke" becomes exhausted, having fulfilled her mission, is deserted by her offspring and left a dead and useless mass of fibre. On grows the tree, sending deep into the ground her roots and high in the air her trunk, until after the lapse of from five to eight years she in turn pays tribute to mother earth by bearing her first, and under favorable circumstances continuing to yield for more than half a century, giving her owner from 100 to 250 marketable nuts a year

Through the centre of the trunk of the coconut tree is a hollow filled with a soft fibrous substance which furnishes the life of the tree and acts as a giant pump in forcing to the nuts the immense quantity of water required to fill them. This fibrous heart has a wonderful filtering or distilling power, for no matter in what location the tree may be growing, either upon the beach or in the malarial swamps with its pools of stagnant water, when nature has done its work, she deposits in the coconut a sparkling liquid as clear as crystal and as cool as if drawn from the deepest well in our northern door yards. Having no particular season for bearing, but bearing all the year round, blossoms, ripe and green fruit may be found on the same tree.

The blossom of the coconut is a most beautiful and peculiar work of nature's art. Appearing at the base of the long, ragged leaves is a dagger-like sheath, green in color, and standing erect until its own weight causes it to bend downward, where it hangs until the stems it encloses, which are to bear and sustain the nuts, are sufficiently matured to proceed on their journey without further protection, when this outer protection drops to the ground, leaving a cluster of ragged stems upon which you will find every few inches miniature coconuts which require about fourteen months to ripen, so that at all times may be found on the same tree nuts varying in size from a walnut to that of a man's head, and some weighing from ten to twenty pounds. Among the many difficulties which the coconut grower has to contend with beside the hurricanes, are the flying fox and the coconut beetle, both of which are very destructive to the young trees, eating their way in all directions into the stems, destroying alike both foliage and fruit, and a still greater enemy to the coconut is the "robber crab" (*birgus latro*), common along the coast of all tropical islands, which subsists entirely upon coconut diet. Finding a fallen nut, he sets to work with his strong claws to remove the tough fibrous covering, tearing it off bit by bit until he reaches the hard shell, when he at once begins to hammer with his heavy claws at the sprout or weakest eye until he has pounded a hole through the meat to the inside. This done, he extracts all the meat with a narrow pair of pincers nature has provided him with. This "robber crab" is equally aware of the value of the fibre obtained from the coconut husk, for he will collect the fibre in large quantities and carry it to his burrow, and lie upon it until some lazy native comes along, digs him out, and robs him of his bed: the fibre obtained from the crab's nest being more highly prized for its fineness than that obtained by hand or machine. From under the dead crab's tail the native takes a lump of fat which, when boiled down will often produce a quart of pure oil, resembling in every particular that produced from the coconut.

GATHERING AND HUSKING.

The sections from which our northern countries receive their supply of coconuts are the northern coasts of South and Central America, Jamaica, Porto Rico and Baracoa, the better grades coming from the northern coast of South and Central America, these varieties having a much thicker meat, and, shelling more readily, are much prized by our best confectioners and bakers. Some idea of the importance of the coconut industry may be formed when I tell you that there were received at the port of New York last year over fifteen million of nuts, and yet there never seems to be an over supply, which is not surprising when one house alone in New York handles over ten millions annually, consuming them mostly for desiccating purposes.

Where coconut culture is made a business, the ripe nuts are gathered from the ground, where they are allowed to drop from the tree, as coconuts are not picked, but to be marketable must drop of their own accord, and allowed to remain in heaps at least a month before husking, in order to get what is termed well cured or browned, when the husk is removed prior to being loaded into the vessel or steamer. The process of husking is simple, yet laborious, and to the uninitiated would be tedious work, but in the hands of the skilled husker the coconut will be relieved of its fibrous covering in three blows upon the sharp point of a stake driven into the ground for that purpose, skilled workman removing the husks from 1,000 cokes in a day. Northern ingenuity has lately invented a pair of husking-tongs, resembling somewhat the tongs used by our blacksmiths for holding hot irons, but differing by having solid, sharp steel points, which, when driven into the coconut husk, will remove it more rapidly and with much greater ease than can be done under the old-fashioned stake system. When husked for market they are piled up in great heaps, or placed under sheds ready for the first vessel or steamer going North, and on her arrival are placed in dories and paddled to the sides of the vessel, which often anchors a long distance from the shore, owing to the absence of docks in many ports of the tropics.

When the vessel is reached the nuts are passed up the sides and counted, and a check given for the same, which, when presented to the captain or agent employed to load the vessel, is paid in cash. If it should be a schooner loading, the nuts are placed in the hold loose, sometimes as many as three hundred thousand being carried in one load. Frequently they are used as ballast in banana vessels, fifty to one hundred and fifty thousand being placed in the hold, with banana racks built above. In steamers where mixed cargoes are carried they are either placed loose in the hold, or put in gunny bags, 100 to the bag. The average loss in transportation is from 5 to 8 per cent, and sometimes as low as 3 per cent; in exceptional cases as high as 20 per cent. This loss is attributed to different causes. Sometimes the nut is not fully ripe or properly cured, and rots, or is over-ripe, and sprouts, or the vessel may be infested with wharf rats or immense tropical roaches, either of which attack the soft eye of the nut, letting the air into the meat, which causes rapid decay. To prevent this destruction the eye of the nut is sometimes covered with a pitchy substance made from tar or rosin, which is particularly distasteful to the rat and roach. Sometimes, so infested with rats and roaches do these coconut vessels become, that before reloading they have to be fumigated or smoked out by burning sulphur in the hold and fastening the hatches down, thus killing the rats that could not be otherwise reached.

When a cargo is ready for sale a gang of men are stationed in the hold with bushel baskets, in which they place such nuts as appear to be good, throwing into other baskets such as are cracked and rotten. Platforms are arranged in the hatches upon which men stand to receive the baskets as they are handed up from below. When they reach the deck the baskets are slid along on a wet board to the dock, where they are counted and loaded into trucks or put into gunny bags, 100 in each, and are then ready to be delivered to the buyer. The buyer establishes its value largely upon the size of the nut and thickness of its meat. If wanted for general market use the question first asked is: "Will 100 nuts fill a double extra gunny bag?" if so, the buyer is usually satisfied, as the size of the nut is what is most appreciated by the average buyer. If, however, the cargo is to be sold to a confectioner manufacturer for desiccating purposes his first question is: "How many pounds of meat will the cargo furnish to the hundred nuts?" That cannot be determined by the size of the nut, for a cargo of Baracoa nuts may be larger in size, heavier in weight, than the same number of "coast" nut. The "coast" nut will furnish more pounds of meat, as the Baracoa nut has a heavier shell, contains more water, and the meat is thinner. For instance, a bag of 100 good Baracoa nuts, weighing 150 to 160 pounds, would probably shell from 50 to 70 pounds of meat, while the average weight of 100 "coast" nuts, being 160 pounds, would yield about 80 pounds of richer meat than any other grade of nuts, the average loss in shell and water being about 50 per cent.

DESICCATING.

In preparing the nut for desiccation the shell is removed by men with small hatchets, who become so expert in the use of that implement that a good workman will remove the shell from about eight hundred coast nuts in a single day, leaving the meat whole and in its round and original shape. It is then passed to men or girls, who pare off with a spoke-shave the brown skin which coats it. (The shavings are sold to soap manufacturers, who extract the oil they contain.) The white meat is next fed into shaving machines, which pare it down to remarkably thin slices. It is then mixed with sugar and placed in drying closets, or upon great plates of sheet iron kept at a certain temperature by steam pipes running in coils underneath the tables, and being constantly and carefully turned by the manipulators. It is finally sorted by sifting into different grades, known as "confectioners' strips" and "desiccated coconut. Nos. 1 and 2."

ITS USES.

In distant lands where the coconut abounds to an almost unlimited extent, and where a market for the nut is not accessible, it is gathered almost exclusively for the 70 per cent of oil it contains, which obtained in immense quantities, the best coming from Cochin China, and the poorest from Cuba, and is shipped to all parts of the world for the manufacture of soap, candles, &c. It is even brought from remote islands in the Pacific Ocean, and sold in the West Indies at a much lower price than the West Indian can make his own oil, as he finds ready sale in northern markets for all the nuts he can raise without breaking them up for oil.

There has been a marked increase in the export of coconut oil from Ceylon, which reached 423,830 cwt. for 1883-84, against 306,299 cwt. in 1882-83, and of this America received 77,902 cwt. in 1883-84, against 61,968 cwt. in 1882-83. The growth of this trade is accounted for by the fact that trees hitherto devoted to "toddy" for the manufacture of "arrack" (the intoxicating drink of the country) have, in consequence of the poor sale for this stuff, been of late cropped for oil. Another reason given for the increased export of coconut oil is the large extent to which kerosene, through its extraordinary cheapness, is finding its way into use with the people of Ceylon. The same is true in China and Japan, where the American oils are fast cutting out the native oils throughout the length and breadth of the land. Coconut oil being more valuable for soapmaking than for lighting purposes, is naturally shipped from Ceylon in answer to the soapmakers' demand rather than consumed at home. But still we believe that the principal explanation of the great advance in oil shipments is to be found in the greatly extended area of cultivation of the coconut palm during the past fifteen or twenty years. In Ceylon alone it is estimated there are growing twenty millions of coconut palms.

In many remote countries, where the advantages of improved machinery for extracting the oil have not been realized, the native digs a bowl-shaped hollow out of the stump of a tree, at the bottom of which he makes a hole, or outlet, and in this receptacle he places the meat of the nuts, then, using a rude press, or lever, worked by the aid of a horse or ox, he extracts the oil, which is placed in barrels ready for shipping, being in a liquid state in its native land, but congealing in any temperature below 74 degrees Fahrenheit. The soap made from this oil is said to be very healing to the skin, and is highly prized on shipboard for its ability to produce a good lather when used in salt water, a quality rarely found in any other soap.

In the manufacture of soap from coconut oil a greater quantity of water can be used than with any other known oil fat, for a solid cake of soap can be made from 75 per cent of water and 25 per cent of coconut oil, with the necessary alkali added.

In England it is largely used in the manufacture of candles. On shipboard it is often used in absence of other oils for signal lights, and in one instance it saved from a watery grave a member of this association. I refer to our worthy member, Captain Bush, of Jamaica, W. I. Having followed the seas for years, and being on one of his trips form Jamaica to New York with a schooner load of coconuts, he encountered a severe gale, lasting for several days, which turned into a perfect hurricane, threatening every moment to carry his vessel to the bottom. His first and second mate, with one seaman, were in bed with yellow fever, leaving the ship in charge of himself, one seaman and a negro boy cook. Nearly exhausted from loss of sleep and exposure, having been lashed to the wheel for two days, thinking every moment would be his last, a tremendous wave swept the vessel's deck of everything movable, carrying in its sweep of destruction oil cask, lamps, &c., so essential to the mariner's safety at night. Having lanterns in reserve in the cabin, but no oil, what was he to do? He at once thought of the oil he could obtain from the coconut, so setting his darky boy to breaking up some coconuts, he managed to obtain sufficient oil to fill his signal lamps and get them in position just in time to prevent a passing steamer, bearing directly down upon them, from cutting the craft in two, thus placing the Bayonne Scientific Circle in debt to the coconut for the life of one of its members. While the oil from the coconut aids the mariner in guiding his vessel over the seas at night, or by its welcome light shed from a distant signal, he his safely led into a snug harbour, we must not lose sight of the fact that the coconut tree figures very largely as a landmark for the sailor to guide his vessel along the dangerous and rocky coasts of the tropics. Of one in particular I will speak. In the harbour of Baracoa is a mountain known by the name of "Anvil Mountain," deriving its name from its close resemblance to an anvil, as it is first seen against the horizon from the deck of a vessel coming in from sea. Upon the extreme end of the Anvil's point is a very tall coconut tree, and it is the first object seen by the sailor as he approaches the end of the island of Cuba, and is as eagerly looked for there as are the Highlands of New Jersey by any vessel approaching our New York harbour. The coconut tree referred to stands entirely alone, and no inhabitants in that neighbourhood are able to tell how long the tree has been there, or by whom planted. A question is often asked, Are coconuts healthy? In reply, I would cite in its favor what happened to a packet ship sailing from San Francisco to Australia with 400 passengers on board, which, on account of rough weather and slow progress, was compelled to put into one of the small islands in the Pacific, where a large quantity of coconuts were obtained. During the remainder of the voyage very heavy weather was encountered, in which the vessel became water-logged, and only reached Australia after a perilous journey of eighty days, during which time all the provisions ran short, and men, women and children were fed only upon coconuts, being at last reduced to one nut per day for each adult. Notwithstanding this diet, not a life was lost and not a single case of sickness occurred, all the passengers landing in a healthy and well-nourished condition. In another instance, two men drifted in a whaleboat on to a desolate island, where they were compelled to remain for seven years before they were taken off, having subsisted almost entirely on coconuts during that time, and yet, when rescued, were in excellent condition and had gained in weight.

While the coconut is considered healthy for men, it is highly prized in the tropics for feeding to poultry, causing them to fatten more rapidly than when fed on grain. In the absence of milk for coffee the coconut furnishes an excellent substitute, by grating the nut, upon which hot water is poured, and when pressed and strained, produces the requiste substitute, of when boiled down to a greater degree furnishes a thick, greasy substance, used in place of butter or lard for cooking.

The green coconut is a staple article in all the drinking saloons of the tropics for making "coconut toddy." The end of the green nut is cut off and from it is poured a glass of water as clear and cold as could be obtained from any hillside spring; to this added such "sticks" as the purchaser may demand.

In a visit to the recent World's Fair at Calcutta, a friend informs me that one of the most novel sights he witnessed was the "coconut sheds," where long tables were arranged, behind which were immense heaps of green coconuts that the natives would cut in two with sharp knives, furnishing you a most refreshing drink of coconut water for a very small sum.

The coconut, furnishing so many useful ingredients, is by no means the only valuable portion of the nut, for the outer covering, or fibre, is becoming world-wide in its reputation for furnishing an excellent substitute for horse-hair when curled and dyed black, and is largely used in upholstering chairs, sofas, mattresses, &c. The fibre when thus prepared is called "coir," and is brought from India where it is prepared and packed in large bales for shipping. There are several factories in New York where this fibre is used in the manufacture of door-mats. In the South Sea Islands the "coir" is highly prized for making cordage or ropes. The time selected for gathering the nuts from which the fibre, or "coir," is to be obtained, is in the tenth month, as the fruit must not be allowed to hang until thoroughly ripe, or the fibre becomes coarse and more difficult to twist, and must remain longer in the soaking pits. The pits in which the nuts are placed a year to soak before the fibre can be properly separated, are in many instances nothing but large holes dug in the ground, then filled with nuts and salt water, on which stones are placed to keep them under and from floating away. After a year's soaking the fibre is easily extracted by beating and rubbing between the hands; the manufacture of cordage is done almost exclusively by women. From three good large coast nuts a pound of "coir" can be obtained, while it requires ten inland nuts to produce the same amount. In the South Sea Islands, where the "coir" roping is used most extensively, they claim for its superiority over hemp rope, its ability to stand a greater strain, owing to its elasticity, which has been proven in several instances where ships furnished with "coir" cables have been known to ride out a storm in security, while the stronger but less elastic hempen ropes of other vessels snapped like pipe stems. Another advantage claimed for "coir" roping is its lightness and ability to float and not become water-soaked; but owing to the roughness of the rope it has met with but little favor in our eastern waters. Experimental tests at the office of the Marine Board in Calcutta resulted in a coir rope of 1½ inches circumference stretching 32 inches, against 9½ inches of the same size rope made of hemp.

A curious hat is made from the husk of the sheath of the coconut blossom, which is sometimes used for a fruit bag, and they are often purchased by passengers on steamers visiting the tropics, when brought to the vessels by natives filled with different fruits and offered for sale at a very small price.

Having said so much in favor of the meat and fibre, we would do our subject injustice if we failed to speak of some of the uses found for the shell.

Besides furnishing the native with his household utensils, it produces an excellent charcoal when properly burned, but as an article of commerce in our eastern markets it figures mostly as a spice adulterator.

The millions of coconuts that are annually used in our markets for desiccating purposes necessarily leave an immense quantity of broken and apparently useless shell, which have found ready sale when ground to a fine powder, and is called "spice mixture." This mixture, although costing but a few cents per pound, is highly prized and eagerly sought for by unscrupulous grocers and manufacturers of spices, who mix it with all kinds of spices in order to undersell their honest neighbour, who is endeavoring to eke out a miserable existence by dealing honestly with the few who fully appreciate fair dealings. Few of us escape taking into our stomachs daily "coconut dust" in the form of cinnamon, allspice, cloves, pepper, nutmeg, ginger and mace, and I am told it is now ground so as to resemble coffee and is used largely for that adulteration, it being odorless and tasteless, and resembling coffee so closely in colour, is with difficulty detected when the two are mixed to gether and both ground to the same consisteney.

A somewhat novel use was found for the coconut during our unhappy civil war. When the Second Virginia Regiment was stationed near Winchester, Va., in the Shenandoah Valley, many of its members having a strong affection for the beverage "applejack," used every means in their power to smuggle some within the lines, but to no avail, the officer in command being a severe disciplinarian —and a strong temperance man—was constantly on the alert, preventing the introduction of what would surely demoralize his army. The keen-eyed sutler, less of a prohibitionist than the Colonel, but with an eye to business, went to Richmond, Va., where he obtained a large quantity of fresh coconuts, had the eye opened and the milk removed, and in its place substituted whisky, corking up the hole nicely, returned to camp with his precious load, which found ready sale at one dollar each. In a few hours nearly every soldier was drunk and high carnival prevailed. The Colonel, in a rage, hunted high and low to discover the smuggler that had caused such havoc in his ranks, but without success, never attributing it to the "milk in the coconut."

While I have presented some of the different uses found for the coconut, and, perhaps, some facts new to many of you, I shall not endeavor to enumerate the 365 different uses the Chinese claim they found for the nut, but will simply close my paper by summing up a few of the uses found for the coconut to which we, as well as the natives, are daily indebted.

Returning home from our daily toil, the first to welcome us as we step upon our porch is the cocoa mat, made from the husk of coconut, and upon which we are invited to clean our shoes. Entering our home, children search our pockets for bon bon prepared from the coconut by the confectioner to undermine their constitutions. Ascending to our chamber to prepare for dinner, we find for dressing our hair a bottle of "Cocoaine," made from coconut oil, and admitted to be an excellent preparation for the hair. On going to our washstand we clean our hands with the most delicate of all soaps, that made from coconut oil, and if our hands are chapped we find in the stand drawer a ready relief in the form of coconut butter, made by the druggist and highly prized for its healing qualities. Thus prepared for our dinner, we descend to the dining-room, where an inviting dinner awaits us, little dreaming that at every mouthful we are to take into our system the coconut in some form. For the seasoning with which the meat is prepared is in many cases largely composed of dust made from ground coconut shells. We lift from the easter the pepper bottle, with which to add more seasoning to our food, thus adding more coconut shell to our already over-adulterated dinner. We find for dessert our cook has tempted our appetites with a custard pudding, upon the top of which floats a preparation of grated coconut, or she has placed a tempting basket of cake covered with a coating of crystallized coconut, and later they are served with an excellent cup of coffee, which they compliment as the best ever drank; but if they were to examine the canister from which it was made, the chances are they would find evidences of ground coconut shell. In the kitchen we find the servant scrubbing with a brush composed of coconut husks, having found its way from the other side of the world, a distance of over twelve thousand miles, yet sold to us for the small sum of 25 cents. Returning to the parlour we recline upon the sofa or easy chair and compliment our upholsterer for the soft curled hair with which he has made our furniture so comfortable, little thinking that if we were to examine its interior we might find it to contain more than one-half coconut coir instead of Russia curled hair, for which we had paid him 60 cents per pound.

Upon retiring we stretch our weary limbs upon a fine mattress and imagine there could be nothing more comfortable, and we thank the inventor of curled hair; yet, were we to examine the inside of the mattrass, the same conditions would likely prevail as in the furniture. No lack of coconut "coir." So that from the moment we step upon our porch at night until we leave our home the next morning the coconut makes itself manifest in some shape or other.

Having previously mentioned the many uses found for the cocouut palm in the tropics, I think we all can heartily indorse the sentiment of that ancient Polynesian, who said, "He who plants a coconut leaves for his children home, raiment and food."—*American Grocer.*

A TROPICAL WILD GARDEN IN BRITISH GUIANA.

COKERITES AND CRUSIAS.—The great features of the place are the Cokerite Palms (Maximiliana Martiana, Karst.), and these are, as far as my experience goes, the most magnificently stately plants in the world. Other Palms and other plants are exquisitely beautiful—some in one, some in other of a thousand ways; but none, it seems to me, equals the Cokerite in its stately grandeur. Even in its young state the splendid mark of its nobleness is upon it, as is apparent in the group of three young examples, as yet unstemmed, but standing 30 feet high; and in their old age they are yet more magnificent. Then their splendid crowns of plumed leafage surmount stems which stand either bare and unclothed in their massive strength, or are densely clothed throughout their length with the persistent leaf-stalks. And when the leaf-stalks are thus persistent they afford roothold for innumerable Ferns, Figs, and other such growths, which add a further grace to the stately beauty of the Palms.

PRICKLY PALMS.—After the Maximilianas the most striking plants here are the Astrocaryums of various species, all impressively marked by their savage armature of prickles. In the second picture of this series the stem of one, an Acqueeroo (Astrocaryum tucuma, Martius) was well shown. In this the prickles, or rather spines, are often 3 or 4 inches long, flat, and terribly sharp. A story is told of a missionary's wife who, for pure economy, used these spines in place of pins for her dress; and it is a fact that in some of the West Indian islands these spines are used as the most apt needless for sowing mattrasses. In one of the photographs is shown a beautiful group of another species, the Awarra (A. tucumoides, Drude), on the dense dark leaves of which the many wild doves about here love to make their nests. The fruits of all the species of this section of the genus Astrocaryum are much relished by Indians, who come from afar and ask to be allowed to pick up the fruits on this hill, famous for their production.

Lastly, my finest group of Æta Palms (Mauritia flexuosa, Linn.) growing among the Bamboos at the river side. It is almost an only native fan-leaved Palms, and is distinguishable as probably of as varied uses as any plant in existence. In proof of this last assertion, I venture to quote from elsewhere some words of my own:—

"The leaves of the Æta are occasionally, but not very frequently used as thatch; but this only, as far as I know, by the Macoosis. The young leaves, just before they expand from the early spike-like form in which they develope, are shaken till the leaflets fall apart; these leaflets are then cut off from the leaf-stalks, gathered into small bundles, and laid on, as thickly as possible, much as straw is used for thatching in England.

"A more important product is the fibre, which is also obtained from the young, spike-like leaves. Each leaflet is detached and treated simply. A sharp dextrous rub with the fingers at the top detaches the outer skin, which is then entirely torn away. This outer skin forms the fibre; the rest is waste. The fibre is boiled, dried in the sun, and twisted, on the naked thigh, into string. Leaves from the younger plants are preferred for this purpose, those from older examples giving, it is said, a fibre wanting in durability. The string is used chiefly for making those most necessary of all Indian properties, hammocks, and is used for this purpose by the Arawaks and Warraus who, however, make their hammocks in two different ways. Eleven or twelve full-sized leaves yield an amount of fibre sufficient for the largest hammock. The string, called *tibiseri* by the Arawaks, is occasionally, but seldom, used for other purposes also.

"I have elsewhere pointed out that the preparation of string or thread, by thigh-twisting, from the fibre of the Æta Palm seems to have been the characteristic of the Arawaks, Warraus, and possibly of other 'native tribes' of Guiana, just as the preparation of string or thread by spinning, from cotton fibre, seems to have been characteristic of all the Carib or 'stranger' tribes.*

"As the leaflets, so the leaf-stalk, which, when dried, is extremely light and buoyant, is turned to a variety of uses. It is used by the Warraus and the few Creole squatters toward the mouth of the Orinoco for the shafts of the harpoons with which they capture fish, and especially manatees. The leaf-stalks are also placed side by side to form walls and partitions in houses by the Creoles of the colony. The Macoosis occasionally raise three or four of the parallel fibres from the outer skin for a distance of about 3 feet, their ends being left attached; those fibres are kept away from the main leaf-stalk by a bridge, like that of a violin, inserted under them at each end; and the whole is then fastened upright on the tops of the house, where the wind playing through the strings produces a very musical sound, like that from an Æolian harp. Sandals are cut by the Macoosis and Arecoonas, who have to walk much on the often stoney savannahs of their districts, from the tough outer part of the sheathing part of the leaf-stalk; and the strings which fasten these sandals on the feet are procured, as above described, from the leaflets of the same leaf. The pith of the leaf-stalk, tough and durable, is cut up and used in various way; cut into long lath-like strips, which are then fastened side by side like the laths of a 'Venetian b'ind,' it is made into very effective canoe sails. Smaller strips are made by the Creoles into neat and often elaborate birdcages. Stoppers for bottles are cut from the same substance.

"The pith of the trunk itself is used by the Warraus as Farine or Sago, and a tree having been cut down for this last purpose, a liquor much appreciated by the Indians, and really very palatable, is obtained from it in the following way:—A hollow is scooped in the uppermost part of the stem, as it lies prone, which hollow, having been protected from the sun by a covering of leaves, is found after a few hours to be full of sap, which presently ferments and forms a pleasant drink. It is said that sugar is occasionally prepared by the Indians from the sap. Moreover, when the felled tree begins to decay, the very large grubs of a beetle (Calandra) are found abundantly in the pith, and are greedily eaten by the Indians, and even regarded as a great delicacy by the older colonists.

"The 'Cabbage' of the Æta is perhaps superior to that of any other Palm.

"The ripe fruit is largely used as food by the Indians, who, after scraping off the Fir-cone like scales, place the whole remaining part of the fruit in water, where, after a few hours, the fairly abundant yellow pulp round the seed become soft, in which state it is readily detached. Pressed into small cakes, this pulp has somewhat the flavour of rather strong cheese. A drink is also prepared by the Indians from the ripe fruit, but I am not sure how this is done."—G. EVERARD IM THURN. British Guiana.—*Gardeners' Chronicle.*

*Among the Indians of British Guiana, London. 1883.

MANURES.

Time was when, with few exceptions, manure was looked on simply as manure, and provided it was of a sufficiently potent nature to be visibly effective in the increased development of some or other of the parts of the plants to which it was applied, it was considered sufficient, and all that was required. Manures of the commonest kind, rich in ammonia, and consequently conducive to the promotion of leaf-growth, were often supposed as all that was necessary; and unfortunately it may be set down as a certainty that too much of this happy-go-lucky sort of proceedinig is still followed with many of the ordinary garden crops—fruits, as well as common vegetables. This especially applies to the host of amatuer gardeners, and to the doings of the so-called gardeners who are intrusted with the management of the smaller run of gardens; not but that such mistakes are often to be seen where better things might be looked for. Yet, that the majority of cultivated plants are not only benefited by, but absolutely require more variety in the food supplied to them than has hitherto been generally supposed necessary, is exemplified by the marked results that invariably follow a mixed diet in the shape of different kinds of manure, when these are applied with judgment—that is, with sufficient knowledge of the requirements of the particular kind of plant to be dealt with. Amongst those engaged in the cultivation of garden produce there are few, if any, whose practice goes so far to confirm

this as that of the leading market gardeners in the different things they cultivate. Pot-plants, Grapes, and culinary vegetables, in their hands, alike show what can be done by the use of different manures. The extraordinary growth and profusion of flowers present in plants grown in pots small out of all proportion to the plants they hold—such as may be seen in thousands in any of the leading market gardens—and the astonishing weight of highly-finished Grapes which Vines under their management annually produce, are conclusive evidence of what can be done by the use of different manures, each rich in some or other of the various elements required to give the highest results attainable with the plants and fruits in question. It is scarcely necessary to point to the practice named as being diametrically different to the course often followed with vegetable crops in old gardens, where for a generation or more nothing has been done but the annual application of stable manure, with possibly the occasional addition of vegetable mould in some shape or other, and with Vines that have had their roots for an indefinite time in borders with nothing to assist them beyond a repetition of the same manure, in which horse-droppings are all but the sole ingredient. Not that there is room to find fault with this well-proved fertiliser, that has the further merit of being readily obtained and easily applied, but it does not alone contain all the elements required to reach the highest standard in the cultivation of the plants under notice, particularly in soil that has been, with little change, long under the same kind of crop. The highest results attainable in the cultivation of the various plants here noticed, and of most others, can only be reached by providing them with mixed food, varied according to the requirements of the different things to be grown, and still further regulated by the nature of the particular soil with which the cultivator has to deal.

This is a subject which young gardeners who feel an interest in the advancement of the pursuit would do well to direct their attention to. The great body of those engaged in agriculture in this country have long been taunted with groping their way, rather than making acquaintance with sound practice. But the schoolmaster, in the shape of the experimental chemist, is now abroad in earnest, and there is abundant evidence that the intelligent portion of those who cultivate the broad acres have their eyes wide open to receive the lessons taught and put them in practice. Gardeners collectively would do well to avail themselves of the teaching, which, taken in a broader sense, is equally applicable to the crops they cultivate.—T. B.—*Gardeners' Chronicle.*

The Soil of New South Wales.—The Colony contains an abundance of soil of the richest description for the support of a very large population, when the conditions shall be more favourable for the pursuit of agriculture, for which in most districts the climate is very suitable. On the coast strip eastward of the dividing range there is a large area of very rich land in the river valleys. It has been extensively cleared, and in the southern part of the Colony is mostly under Lucerne, Corn, and Potatos, and yields immense crops. On the northern river-flats splendid crops of Sugar-cane are grown, as well as of Corn. The Tobacco-plant flourishes on this strip of land, as well as almost all the cereals and fruits of temperate and semi-tropical climates. Wheat crops formerly were grown extensively here, but for many years past the area planted with Wheat has been very much reduced, owing to the extreme liability of the grain to rust when coming into ear. It is this that has doubtless rendered the production of Wheat in the Colony so far behind the yield of the southern Colonies. However, when we get on to the table-lands we find a large area of soil of very rich quality among the surrounding rocks and country of granite formation, and this promises to be the future granary of the Colony. At present the yield of the crops in some instances amounts to as much as 30 and 40 bushels per acre from the virgin soil of this part of the Colony. Here flourish the English fruits—Gooseberries, Cherries, Currants, and the like. As you go further westward the climate becomes less and less favourable for agriculture, owing to the uncertainty of the rainfall, and, as far as present appearance indicate, the great salt-bush plains of the interior, unrivalled for fattening stock, will for generations to come be chiefly devoted to that pursuit. With regularity of seasons agriculture might be possible, but the rainfall is very irregular in that part of the colony. Briefly summed up, we may say that the coast climate and soil favour the production of almost all kinds of vegetation found in temperate and semi-tropical regions; that the table-lands, with a magnificent climate, will produce all the cereals and fruits of the temperate zone; while away westward are hundreds of thousands of square miles of the finest stock-fattening country to be found in any part of the world.—*Gardeners' Chronicle.*

Changes Induced by Cultivation.—Interesting examples of the leaves of Sagittaria montevidensis were exhibited by Mr. W. T. Thiselton Dyer before the Linnean Society, on December 4. The small leaves were from a plant raised from seeds collected in Chili by Mr. John Ball, F.R.S., and sent to Kew in 1883; these were grown in a pot half submerged in the Nymphæa tank. The enormously large leaf and spike were those of a plant raised from seeds ripened at Kew and sown in the spring of 1884. When strong enough the plant was planted in a bed of muddy soil, kept staturated by means of a pipe running from the bed, to the Nymphæa tank. The changes thus induced were so great and remarkable as regards size and general facies, that without exaggeration, and if their history had not been known, they might have been deemed plants of widely seperate genera.—*Gardeners' Chronicle.*

Tea Planting in Assam.—Some sound advice is given in a book by Mr. Barker ("A Tea-planter's Life in Assam"): to any man, says Mr. Barker, thinking of emigrating to Assam on the speculative chance of finding something to do, with no situation to step into on arriving at his journey's end, "my advice is, let him exhaust all his available interests to obtain something to do at home, even though it be put a poorly paid office." Comparatively large salaries are occasionally offered in Indian advertisements for billets in Assam and other up-country regions, equivalent to £150 per annum to begin with; but the author warns that this amount just enables a man to live, and that is all; and good living is an absolute necessity to fight against the treacherous climate. The life is much harder than that required by any regular home profession or trade, the hours are severe and irregular, the variations of temperature very trying, and there is an ever-present unquenchable thirst which requires superhumau restraint, as to drink in the home sence is to die.—*Field.*

Japan Plum.—The Plum was exhibited before the Fruit Committee on October 14 last, by Mr. Bull. The fruits attracted much attention, being much more like Nectarines in colour than Plums, though, it is true, more elongated in form. The flesh is firm, yellow, and of good flavour, and as Mr. Bull received the fruit direct from California, whence it arrived in good condition, nothing further need be said as to its qualifications as a traveller. The tree was introduced from Japan to California in 1871. According to the *Pacific Rural Press*, the tree is very prolific, and Messrs. Hammon & Co., of Oakland, who have propagated it, claim for it these merits:—"1. Its wonderful productiveness is unsurpassed by any other Plum, either native or foreign. 2. It comes into bearing at the age of two to three years, and continues with great regularity, blossoms frequently appearing on yearling trees. 3. The fruit is of very large size, being from 7 to 9 inches in circumference, and specimens weighing 6½ oz. each, and it has a remarkably small pit. 4. It is very attractive in appearance, being of a rich yellow nearly overspread with a bright red, with a lovely bloom. It is heart-shaped. It ripens from first to last of September, at a most favourable time for harvesting and marketing the crop, the larger part of the Plum crop being gone. 5. It is of superb quality, melting, rich, and juicy; in fact, to some tastes, at least, has a more satisfying flavour than any other Plum. For cooking, jelly, or preserving in any manner it has no equal. Its large size renders the paring of the fruit as practicable as in the Peach, which is quite a novelty in the line, and excels all other canning Plums. As a dried fruit it is destined to take the lead, equal to if not surpassing the best dried Prunes or Peaches for drying results."—*Gardeners' Chronicle.*

THE UNDEVELOPED RESOURCES OF UVA, CEYLON.

A writer who gives the initial "R." sends to a comtemporary the very interesting paper which we give below on the geology and mineralogy of Uva. Gold exists in Uva as everywhere else in Ceylon, and, while Mr. Campbell in his "Circular Notes" wrote of the "marbles" of the country around Anuradhapura, "R." speaks of veins of marble in Uva capable of taking a polish equal to the product of the Carrara quaries. The paper supplies a new argument for railway extension :—

I am of opinion that in this peculiarly formed basin lies a considerable amount of mineral wealth, requiring only roads and railway communication to open up and develop new and important industries in the island.

This is important, but more important still is the verdict in favour of large portions of the Uva patenas for agricultural purposes.

There is also a notice of the fertile *peroxide* of iron and the barren *protoxide*, to the predominance of the latter of which salt of iron the Rev. Mr. Abbey traced the barreuness of the uplaud patanas. We may venture the prediction, that, with "the circling of the suns," and the advance of science, means will be discovered of ameliorating protoxide soils by aeration and otherwise. Plumbago has been described as one of the oldest formations in the earth's crust, and the writer of the paper we are referring to indicates a belief in the possibility of even coal being discovered in the basin of Uva.

GEOLOGY AND MINERALOGY OF THE BASIN OF UVA.

GOLD, MARBLE, PLUMBAGO, AND IRON ORE.
FERRUGINOUS PROPERTIES OF ITS ROCKS, AND SUITABILITY FOR TEA, &C.

SIR,—By parcel post I send you samples of various minerals obtained in a short exploration of the hydrographical basin of Uva, and would be very pleased to have your opinion upon them.

The gold, you will observe, is imbedded in *chlorite schist*, where I had not expected to have met with it in such large quantities. Whether it be prevalent, or is only sparsely distributed in this class of rocks, I am unable yet to say. The other minerals, with the exception of the marble, I may state, are not partial deposits, but extended over a wide extent of district, and I am of opinion that in this peculiarly formed basin lies a considerable amount of mineral wealth, requiring only roads and railway communication to open up and develop new and important industries in the island.

I regret that I have been unable to procure in Ceylon the necessary materials for polishing the marble; consequently I have only been able to operate upon it as far as to enable me to perceive that it is capable of receiving as brilliant a polish as the famous marbles of Sicily and Carrara. By leaving it, however, a few minutes in a basin of water, and then holding it at a angle towards the light, you will be able to realize the same effect it would exhibit on being polished.

The patana hills, for the most part, consist of *trap* rocks, and, with the exception of the slopes of the encircling mountain range, (the mineral formation of which is chiefly *gneiss*, or its varieties), are as a rule barren and too deficient in carbon for the cultivation of vegetable products generally, but some fine alluvial deposits are to be met with on the *flats*, and in the valleys and hollows of this wide tract of country thousands of acres which only await capital and European enterprize; and, in my opinion, are better adapted for the cultivation of tea than many kinds of jungle land, if ferruginous soil be considered a desideratum. Although this property may be the general characteristic of the soil in most parts of the island, I think that the soil of the Uva basin possesses it to a much greater extent than any other part of the country with which I am acquainted, unless it may be the *subsoil* around Colombo, which chiefly consists of *laterite*, *i.e.*, decomposed trap, with red oxide of iron, the same which constitutes the soil of the trap rocks of Uva.

There are, however, two kinds of oxides of iron found in almost all soils, viz., the *protoxide* and *peroxide*, and I have not been able to ascertain, from analyses which have hitherto been made of Ceylon soils the relative proportion of each of these two salts of iron. But this is a very important matter for the tea planter to know, as soils which contain the protoxide, even to a very small extent, soon become barren, unless heavily manured. In soils formed from the decomposition of *syenite* and *hornblendic* gneiss, protoxide of iron may be found to predominate, some kinds of hornblende containing as much as 22 per cent of it, along with salts of *manganese*.

On examining the gneiss of the Totapela, Nowara Eliya, Kandapola, and Udapussellawa ranges downwards to the centre of the Uva basin this series of rocks is found to vary from a compact *granitic* and highly-crystalline nature to laminated hornblende and chlorite schists, graduating into fine white sandstone of the consistency of a Newcastle grindstone, then into loose unindurated sandstone. These form the soil of a certain portion of the undulating hills, whilst a great many are formed entirely of purely *subaqueous* deposits, varying from 50 ft. to 100 ft. in depth.

During the late unprecedented rains some enormous landslips have occurred in this district, carrying away, in one instance, the whole side of a hill, about 500 feet in height, revealing at once the formations of untold ages. Here I have discovered a set of perfectly stratified sandstone rocks, from 80 feet to 100 feet in thickness, and about 200 hundred feet beneath the surface of the adjoining hills, imbedding large round water-worn *boulders* 1 cwt. to over a ton in weight. They appear to be a red sandstone formation, but in the absence of a single *fossil* it is impossible for me to say to what series they may belong.

It has been asserted by some writers on the geology of Ceylon that none of the stratified formations, *posterior* to gneiss, had ever been found, and that probably they never would. If this were the case, we should be obliged to suppose that during the periods of the accumulation of those formations in other parts of the globe, this island must either have been dry land or that it was not in existence, or existing only beneath the waves. From the very fact, however, of the existence of plumbago alone, such could *not* have been the case, and we are thus led to assume that Ceylon, as an island or part of a continent, must have been more than once submerged and upheaved, and, if plumbago had at one time existed as coal, as Sir Charles Lyell imagines, the last general upheaval must have taken place subsequent to the carboniferous period.

It is also a remarkable coincidence that whatever may be the circumstances under which plumbago is met with in other parts of the island, in Uva it is found amongst the *detritus* of decomposed trap rock. It was also in the neighbourhood of these igneous rocks, where I met with the marble and clay iron-stone.

With the exception of gold, all these minerals are, in England, associated with a coal field, and I am of opinion that if coal be found to exist in Ceylon, it will, most likely, be met with in the hollows and basins of the trap hills of Uva.—R.—"Times of Ceylon."

PLANTERS' ASSOCIATION OF CEYLON.

The following are extracts from the 31st annual report for 1884-85 of the Ceylon Planters' Association read at the annual meeting on 17th February 1885 :—

New Products.—Your Committee congratulate you on the largely increased exports of all new products.

Tea.—The congratulations which your Committee was able to offer you last year on the great progress made in the cultivation of this product can be repeated this year with increased force. Your Committee recognize the fact that it is to tea mainly that the planting community and the colony must look for a return of general prosperity, and there are already signs that a measure of that prosperity is not far distant. During the past year in almost every planting district the greatest activity has been displayed in planting up both old and new land with tea, and in the more advanced districts large factories and the most improved machinery have been erected. Individual estates and clearings have yielded unprecedented crops, and, although these phenominal yields are no guide to the probable average out-

turn of the planted area, still they show the suitability of much of the Ceylon soil and climate for the cultivation of the rising staple. Ceylon tea is no longer a fancy article, but sells on its own merits, and your Committee cannot too strongly urge upon every planter the desirability of keeping the quality of his teas up to a high standard. Your Committee have noted with satisfaction that representations in Council were successful in getting tea-lead exempted from duty, and your Committee are of opinion that concessions in railway freight on the upward transport of lead, boxes and other tea requirements should be made. Pursuant to a resolution passed by the Association, the Chamber of Commerce was asked to fix an agency rate for tea. It would almost seem as if the Chamber had misunderstood what was meant, as it fixed 2½ per cent on invoice value, together with actual costs incurred. As the work can be efficiently done for ½ cent per lb. your Committee doubt whether much advantage will be taken of the rate fixed by the Chamber amounting as it would on an average to about 2½ cents per lb.

Cinchona.—The extension of the cultivation of this product has suffered a considerable check within the last year or two owing in part to the very considerable area of the planted land proving unsuitable to its profitable cultivation and in part to the very serious decline in the market value of bark. Still though cinchona has failed to fulfil the very high expectations originally formed, and though its cultivation will be much more restricted than was at one time hoped, it nevertheless continues to be a very important product and to promise remunerative results over a considerable area. Your Committee would recommend to those who possess suitable land the desirability of not overlooking this product which may become as a subsidiary cultivation as profitable in the future as it was in the past. The exports of the past year show an enormous increase upon those of any former year being in fact in 1883-84 11,492,947 lb. against in 1882-83 6,925,595 lb. This large increase however must not be regarded as a measure of the increase of the cultivation as it has resulted to a great extent from the harvesting of bark to meet financial necessities and to provide the means of planting tea and other products in localities where it has not fulfilled expectations.

Cacao.—The attention of your Committee was directed in the autumn of 1884 to the serious damage this cultivation was reported to be sustaining from the attack of an insect now well-known as *Helopeltis Antonii* on certain well-known estates. Your Committee lost no time in having the subject ventilated and appointed an influential Sub-Committee consisting of three experienced cacao planters associated with the Director of the Royal Botanical Gardens at Peradeniya. Dr. Trimen, Messrs. Jardine, Ross and Vollar inspected various estates in the several cacao districts of Kurunegala, Matale and Dumbara and drew up a long and interesting report which will be embodied in the annual volume of the Association's proceedings. In addition to this report, the Committee have pleasure in drawing attention to a paper on cacao and *Helopeltis* in Matale, kindly furnished to the Committee by a cacao planter in that district, Mr. Martin. The impression left in the minds of your Committee is that the attacks of this insect are aggravated by the condition of the trees during or after a prolonged season of drought and that shelter and in some cases shade minimize it evil effects.

The exports for season 1883-84 reached 9,853 cwt.
Do do 1882-83 „ 3,588 „

a very satisfactory result which forcibly demonstrates the important position this product has reached. There is little doubt, that, given suitable soil and climate and not adverse seasons, these figures will in time not only be maintained but be increased. In connection with the pest *Helopeltis Antonii*, your Committee had the honor to convey your thanks to Government for a copy of Dr. Trimen's most interesting and valuable letter on the subject.

Cardamoms.—The increase in the export of this valuable product is very marked: in 1883-84, 66,319 lb. against 21,655 lb. in 1882-83. Your Committee trust that the market value of the article may be maintained notwithstanding this large additonal supply and that its cultivation will continue to be a source of revenue to those engaged in it. Certain districts favoured with a good average rainfall have done well last season which was comparatively a dry one.

Rubber.—Your Committee have no further information to lay before you regarding the best and cheapest method of collecting this produce or determining the age at which the harvesting can be safely commenced. Cacao planters in Dumbara believe that Ceara rubber trees afford good shade and shelter for cacao and are planting it extensively. It is therefore to be hoped that it will in addition form a source of revenue if a suitable method of harvesting the rubber can be devised.

Grub and Leaf-Disease.—The attention of the Association has been directed to the two principal pests that have caused the alarming decline in the production of coffee. Regarding leaf-disease little that is new can be said. It still continues its ravages. With reference to grub, the thanks of the Association are due to Dr. Trimen and Government for having obtained the opinion of Mr. Mac Lachlan which disposes of the doubts cast upon the commonsense proceeding of catching the chafers. The life of the female is not so ephemeric or its fecundation so rapid as was supposed. Although the pest has increased greatly in portions of Dimbula, it is gratifying to record that in Maskeliya and some parts of Dimbula it has almost passed away. Your Committee have also to chronicle the reappearance, to a very serious extent in certain parts of the island, of black bug which is virulently attacking coffee that had hitherto to some extent resisted the ravages of leaf-disease and grub.

Specimens of New Products.—The very valuable nucleus of a collection of specimens of new products which was temporarily forwarded to the Calcutta Exhibition has now been handed over by your representative, Mr. Capper, to Dr. Trimen, and are now in the Museum of the Royal Botanic Gardens at Peradeniya. Your Committee trust that this collection will continue to be largely augmented from time to time.

Ground Nuts.—This staple article of export from Pondicherry, has commenced to arrive in small quantities, but owing to the uncertainty that prevails as to the outturn, the present quotations, are purely nominal, and not to be depended on; last year the rate during the shipping season varied from R11, to R16 per [French candy (560lb. English). The crop is lost, almost entirely within a distance of twenty to twenty-five miles from the coast.—*Madras Mail*, February 9th.

Insects.—Next to the mealy-bug, I consider the white-scale to be the most troublesome insect; there is some of this but not on the Pines, I am glad to say. The conservatory climbers have been troubled with it, but now I hope to get rid of it from among them. Had I feared it as I do the bug, there would not have been any left. Our practice for white-scale has been to use an insecticide at double the strength advised on printed instructions; this I have found to be more than they can withstand. Brown scale, thrips, red-spider, and aphides, are likewise very troublesome pests. A watchful eye needs be kept on each and all of them, and measures taken to destroy them. It is grievous to see the damage that is done by omitting to take such matters in hand at an early date, the effect not being obliterated for a long time to come in some cases.—James Hudson, Gunnersbury House Gardens, Acton, W.—*Gardeners' Chronicle.*

Manure is "the soul of agriculture;" in market gardening it is soul and body too. "The more manure the more Rhubarb," is a common saying among men who sometimes apply 100 tons of dung per acre at a cost of £30 or £10. In opposition to a great deal of misleading counsel in the papers farmers have had the advantage of listening to Mr Glenny, of Barking, who discoursed upon our subject, with full knowledge of all its details, before the London Farmers' Club. Some time since, when we saw Mr. Glennys' market garden, it consisted of 116 acres under vegetables, the manure bill amounting to about £800 a year, and the labour bill to £1,500, the number of horses engaged in cultivation and in the cartage of produce and manure a distance of 8 miles, to and from London, being a dozen, instead of only four which an ordinary farm would require. A prudent farmer living outside the proper limits will pause before he enters upon such a business as Mr Glenny's.—*Gardeners' Chronicle*

THE COUNTRY FOR RICE-GROWING.

Mr. Hallett is the coadjutor of Mr. Colquhoun in promoting Railway Construction from British Burmah to Siam, the Shan Country and the borders of China, and he has been giving a glowing account in Calcutta of the richness and populousness of the interior. When his railway is made, the supply of rice for export from Burmese ports will be indefinitely increased. To take one instance, Mr. Hallett reports :—"The people in the Kiang Shen State told him that the land was very rich ; that last year the outturn of paddy was 250 times what they had sown." Most certainly the day is coming when Burmah and Northern India will supply Ceylon with all but an infinitesimal portion of the rice we require at a far cheaper rate than it can be grown here ; and the sooner, therefore, our Government and revenue officers direct the attention of the people to the industries for which our climate and other conditions are peculiarly adapted in the several provinces, the better. At present we have the anomaly that the Ceylon authorities only spend money, comparatively, to increase the breadth of rice culture, while the Commissioner for Burmah, Mr. Bernard, is most anxious to supplement the splendid agricultural resources of his province, by a planting industry in tea, coffee, cacao, rubber, &c. In Ceylon, with only a few meritorious exceptions, the revenue officers ignore planting or new products among the natives.

THE USE OF TREES IN WAR.

The War Office has directed the immediate attention to the planting of suitable trees to mask works of defence, and the question has been fully discussed in Madras. As the matter may require attention in Ceylon we quote as follows :—

Letter from Colonel McLeod, to the Agri-Horticultural Society, dated 14th December, 1884 :—With reference to the enclosed, I had told Colonel Burton that, in my opinion our Society could give him the best information on the local shrubs and trees that could be made available for masking purposes. The requirements are of 4 kinds: To cover mounds and conceal their outlines. For this I think "Ipomæa pescapræ and Spinifex" would probably be suitable. Shrubs to the height of 6 to 9 feet to carry on outline and merge it in the surrounding country. Probably Divi divi, Screw pines, and coppiced Casuarina and Corkapillay would answer. Trees to mask batteries should grow from 20 to 30 feet. Casuarina, Portia, Palmyra would assimilate to surrounding scenery I think. For abattis or obstacles, Corkapillay, Aloe, Babool. There is no doubt that you can give much fuller information and particulars as to time of sowing, watering, cutting, &c., and if you will take the matter into consideration, the Society might make a communication to the Commanding Engineer on the subject ; and with a view to put it in a correct light, I have endorsed the letter to me to you as Honorary Secretary.

Notes by the Honorary Secretary, Agri-Horticultural Society, on the subject :—Having many years ago watched the skilful arrangements of the Engineers to mask some of the batteries erected for coast defence in England, it is comparatively easy to understand what is now required for the batteries at Madras. Presumably the main objects of the Engineer are really two, (1) to conceal the position of the gun or guns without in any way obstructing the view of the gunners or interfering with the efficiency of the fire from the batteries, and (2) to delay and impede an enemy attempting to get to close quarters with those working and protecting the guns ; and assuming this presumption to be correct, the question now to be considered is how best to carry out these objects with the materials at hand. From the War Office Memorandum it appears that the most approved plan of attaining the first object is by planting masses of trees in rear, and raising natural-like mounds in front and on the flanks of batteries ; and the latter by entanglements of low and close growing trees or thorny shrubs. To answer at once all the purposes required probably nothing could excel the casuarina ; and, as for many miles North and South of Madras, little else is to be seen from the sea but dense casuarina woods, a few extra lines and clumps along the sea face of the town would certainly not attract attention.

Taking the case of the battery near the Light-house :—a thick belt, or even a double or triple avenue of casuarinas running along the road side, say from Messrs. Parry & Co.'s office, then nearly to the glacis of Fort St. George, swelling out here and there into deep clumps, in one of which the battery might be embowered, would most effectually break, or in fact obliterate the sky line of the battery itself. On the sea side the plantation would naturally take the form required. Probably no tree is more tolerant of the sea wind, or when the tender tips are blighted sends out so strong a growth to fill their places. The nature of the tree is to seek for sunlight and air, so when its under branches are uncut and untrammelled by neighbouring obstruction they shoot out along the ground, struggling to get from under the shade of those above them. The nipping off of the tender tops of two or three outer, or seaward lines of trees by the wind seems to throw greater strength into their lower and outward growth. The leaves falling from above and particles of sand, sea-weed, and other animal and vegetable matter blown by the wind against the line of trees form a sort of hotbed in which the trailing branches readily take root and send out countless suckers, and each sucker in its turn repeating the process, a slope of dense growth is in course of time formed from the water's edge to the tops of the highest trees behind. Such a plantation might be made even in front of the battery, as if clipped while young, the trees can be kept to any required height, and the dense intertwining of their branches on the sea side would form a fairly efficient entanglement.

In planting casuarina the only requirement is that the tap root be directed straight downwards, and that the young plants have sufficiency of water. The former is best attained by raising the plants in baskets and planting them out, baskets and all, before they grow too large ; while there is no difficulty about the latter on the sea beach where sweet water can be found any where by digging a few feet. If the plants be set out about June they should require watering in dry weather for two years only. The plantations would of course require to be carefully fenced to keep out fuel-gatherers, cattle, and particularly goats. Every leaf that falls should, though inflammable, be left on the ground, as the trees thrive much better, that is to say, are more dense in foliage and rampant in growth, when their roots are so covered. The continuity of the inflammable surface would necessarily be broken by the approaches to the shore crossing the plantation. For fencing, in preference to all other forms, a ditch and low bank crowned with two rows, say two feet apart, of Agave vivipar, commonly known as Indian aloe—not Agave americana as used for the Railway fences, and not Fourcroya gigantea as now used at the batteries as both are shorter lived plants, needing more frequent renewing—may be recommended. The bank of sand would be improved by having a little admixture of stronger soil both to hold it together and to stimulate the growth of the agaves. Many other trees would grow well if sheltered at first, as they would be immediately in rear of the batteries; and if variety be desired Coorcapillay (Inga dulcis), Portia (Tespesia) populnea, Banyans and several other species of Ficus Cashewnut (Anacadium occid-

entale), Laurels (Calophyllum inophyelum), Palmyra and Date Palms (Phœnix sylvestris) and many others may be mentioned but none of them combine all the advantages that the casuarina does, and none of them would so well harmonize with the general appearance of the coast.

If rough mounds of sand be preferred to hide "the smooth, well trimmed slopes and sharply defined angles" of the battery, they must be fixed in situ as suggested by Colonel McLeod by a covering of sand binding plants, such as Ipomea pes-caprae, Spinifex squarrosus, Hydrophylax maritima, Microchynchus sarmentosus, Sesamum prostratum, or the like; but perhaps an objection to this plan might be that to keep these plants thoroughly efficient in the hot weather they would need attention, which would make more or less of a green spot, or oasis, easily distinguished from the sea. Probably it would be preferable, unless clipped casuarina be used for this purpose also, to plant a broad belt of thorny shrubs such as may be found growing in similar positions along the coast. First among such shrubs may be named the screw-pine (Pandanus odoratissimus), which as a ragged screen with a most irregular outline, would serve the purpose admirably, while sea-breezes would so curb its rampant growth that little attention would be needed to keep it low. The screw-pine too has the great merit of being very easily grown and transplanted, all that is required being to stick the tops of branches into the sand at the beginning of the rains and they will root and spread without further care. Amongst the sand-hills on the coast near Madras, are to be found growing naturally many shrubs and creepers which would excellently serve the required purpose. The dwarf date Palm (Phœnix farinifera, Roxb.) is very common, forming dense masses of spines, usually under nine feet high; and with it flourish abundantly other thorny shrubs of lower and weaker growth, such as Gmelina asiatica, Carissan carandas, Guilandina bonducella, Teddalia aculeata, Calamus sp., Capparis horrida, Capparis divaricata, Zizyphus œnoptia, Ilugonia mystax, and Griffithia fragrans. Many of these shrubs can be easily grown from seed, as can many others of thornless species which associate with them but there might be much difficulty in getting some of them as their roots ramble so far in the sand that transplantation is next to impossible.

For an entanglement nothing could better serve the purpose than broad zones of the plants mentioned above. The following ideal obstruction would stop even an elephant:—First a belt of Agave vivipara planted on low banks, row after row, then a ditch with its bottom thickly planted with Calamus sp. (The wild rattan which commonly grows in such situations near Madras). Next a few lines of plants and shrubs such as Coorcapillay, dwarf date, Screw Pine, Zizyphus œnoptia, and Gmelina asiatica, overgrown, twisted, and bound together by the long thorny trailers of Capparis horrida Guilandina bonducella and Teddalea aculeata; and within all a dense fringe of clipped casuarinas behind which the defenders could unseen arrange a warm welcome for man or beast hardy enough to face the thorns.—*Madras Mail.*

THE GEOLOGY OF MADURA AND TINNEVELLY.

From an article in the *Madras Mail* reviewing a paper by Mr. Foote of the Geological Department we take a very interesting extract referring to the formation of Adam's or Rama's Bridge between Ceylon and India and the curious banks of red sand so conspicuous in parts of the Madras Presidency and also in Travancore:—

The chief geological interest, of course, lies outside of the gneissic area on the strip of country, reaching from the coast line for a varying distance inland, which is occupied by the more recent rocks. This area is chiefly covered with gritty sandstones belonging to the Cuddalore beds, lateritic conglomerates and alluvium, but it also contains several small sub-recent marine beds of limestones and grits, which are given in the table as "upraised coal reefs," but this, we fancy, must be a misprint for "coral reefs." Perhaps the most interesting of these upraised coral reefs is one which forms a striking feature of the north coast of the island of Rameswaram and apparently extends from Pamban to Ariangundu as a narrow strip, and then widens out to the north-eastward to form the northern lobe of the island. This northern lobe seems to owe its existence entirely to the upraising of the coral, which is here covered by only a thin coating of alluvium. At present the reef rises above the water-level for at least ten feet, thus showing a considerable upheaval of this part of the coast in comparatively recent times. This is a circumstance which ought not to be lost sight of by the promoters of the scheme for cutting a ship canal across Rameswaram, a scheme which Mr. Foote unceremoniously speaks of as "wild." There is no means of determining exactly when the upheaval took place, but, as Mr. Foote suggests, it seems probable that it was this upheaval which gave rise to the formation of "Adam's Bridge," which according to local tradition, once joined the island of Rameswaram to *terra firma* on both sides, and was breached about A.D. 1480 by a tremendous storm. When we consider that plutonic agencies do not seem to be quite quiescent even yet on this coast, it appears by no means improbable that Adam's Bridge or Rama's Bridge, as the Hindus call it, was formed suddenly by the action of subterraneous forces, and the mythical tales regarding its formation by an army of monkeys are easily explained. So too is its subsequent destruction by a storm, which was facilitated by the system of jointing which crosses the barrier nearly at right angles.

A very marked feature of the surface geology of the southern districts is produced by the so-called "Æolian Formations," consisting of blown sands, 'teris' and coast dunes. Of these the teris are the most important, and hitherto there has been some difficulty in explaining fully the mode of their formation. The solution of the difficulty offered by Mr. Foote is very simple, but quite satisfactory. During the prevalence of the South-west monsoon heavy gales blow almost continuously for months together. By these gales great clouds of red dust are swept up from the broad belt of loam which skirts the eastern base of the ghats, and are carried along eastward till they meet the sea-breezes near the coast. The North-East monsoon would of course tend to neutralize this action, but it is usually far less violent than the South-West one, and is accompanied by heavy showers which tend to fix and consolidate the blown sand. In fact the action is similar to what we see going on, on the south side of the Madras harbour, where, in spite of the counteracting influence of the North-east monsoon, the sand is being steadily heaped up against the breakwater. Some of the geological changes produced by these teris are very important. Thus Mr. Foote points out that there are several fresh water lakes in South-east Tinnevelly which have been formed solely by the damming back of the local surface drainage by these hills of red sand. The most important of these is the Taruvai lake, which is surrounded by these teris on three sides, and is really a natural lake, though entered in the district maps as a tank with an artificial bund. The view across this lake which in wet seasons forms a fine sheet of perfectly fresh water, is described as a very remarkable one, and possibly unique, the pure and intense red of the foreground forming a bold contrast with the green of the mid-distance, and the varying blue tints of the background and sky. Another

important feature of the teris is the way in which they absorb almost all the rain that falls upon them and give it out in springs near their base, where it is collected and used for irrigating fields. On the other hand the advance of the teris has often done considerable damage by burying fields and gardens, and, in some cases, even houses. The rate of advance of the sands on the Ishamoli teri between 1808 and 1868 was on an average seventeen yards per annum, but they are now moving much less rapidly, and in the four years from 1869 to 1874 the advance was only twenty-four yards. Much has been done here, as in France, to stop the movement of the sand by the extensive planting of trees, and there is every reason to believe that they will in time be all changed into fairly fertile soils.

The consideration of the ecooomic geology of Madura and Tinnevelly takes up a very short chapter in the memoir. The only metal found is iron, and that not of the best quality. At one time it was worked to a considerable extent in the Pudukotah State, but the scarcity of wood at the present time has entirely stopped this industry. Building stone and limestone of excellent quality are found in many parts of the districts. For the former both laterite and gneiss are used. In the Shenkarai and Shakkotai tracts laterite of a very fine quality is obtained in blocks which reach the large size of 8 feet, by 1½ feet, by 1 foot. Some of the gneiss in the district are easily quarried and yield handsome stones capable of taking good polish, which would, in Mr. Foote's opinion, render them equal in beauty to the finest Peterhead granite. The crystalline limestone of Pantalagudi, Tirumal, and Shenkotai would yield an inexhaustible supply of beautiful pale grey, grey and pink, pink, and pink and green varieties of marble of high quality, but at present they are used only as rough stones. The memoir is accompanied by a well executed geological map, on a scale of four miles to an inch, which ought to prove a very useful companion to any one who has to travel through these districts.

THE SIROCCO TEA DRIER.—Messrs. W. H. Davies & Co. send us the result of experiments made by Messrs. Davidson & Co., showing the important effect of using light or heavy charges of material on the trays, and they mention that with No. 3 Sirocco it will be almost impossible to load the trays too heavily with tea leaf.

COFFEE CULTURE IN BRAZIL AND JAVA.—A correspondent writes:—"My attention has been attracted by the report of a lecture given before a meeting of the Indian Association at Amsterdam which appeared in the *Indische Mercuur* of the 17th January, and I have since been busy with the translation, which I have just finished. As you alluded to Mr. Van Delden Laërne's report of his mission to Brazil, it struck me you might like to have a translation of his address to the meeting abovementioned. 1½ lb. per tree of coffee is an enormous crop, but I see some of the persons mentioned by Van Delden reckon on that quantity."

PINUS SINENSIS.—The *Gardeners' Chronicle* tells us that the trees of Pious sinensis adjacent to the Wong Lung Kun Monastery, 50 miles from Canton, are very fine indeed; but they are exceeded in magnificence by those of the So Liu Kun Monastery, secluded at an altitude of about 800 feet, where six of them, within a radius of about 50 yards, in a dense mixed forest of luxuriant-trees, averaged 11 feet 7 inches in girth at 6 feet from the ground, and about 150 feet in height. The largest of them was 15 feet 4 inches in circumference. A pine tree which had been blown down and was being cut up I measured, and found its height to have been 102 feet circumference at 10 feet from the ground 7 feet 10 inches, and it had seventy-five annual rings.—*Gardeners' Monthly.*

Correspondence.

To the Editor of the "Ceylon Observer."

THE IMPROVED TEA ROLLER ON ELKADUWA.

17th February 1885.

SIR,—Your correspondent "Peppercorn" is, like all "guppers," incorrect in his remarks about a tea-roller in your issue of the 16th instant. The machine he refers to is a Jackson's hand roller now working on Elkadua. The suggested improvements, which increased the outturn of the machine, were made by the manager of the Elkadua group, and carried out by Messrs. John Walker & Co., Kandy, and it is to the ingenuity of the former alone that we are indebted for the improvements. "Peppercorn" has n't invented any machinery of his own that we are aware of, or doubtless we should have heard of it before this; when he does so with success, it will be time enough to run down Indian men in general, Jackson and Kinmond included with the rest *

"Peppercorn" has been, I note, in search of a bad field of tea: if he would look nearer home instead of prowling about the "highways and hedges," it is not unlikely he would find one. KAMRUP.

No. II.

Our District, 18th Feb. 1885.

DEAR SIR,—"Peppercorn" in his letter published in your issue of 16th inst. goes very particularly into the items of tea rolled on the Elkadua estate by Jackson's roller as arranged by Mr. Fleming, but he ("Peppercorn") omits to say that a *very powerful* water-wheel is attached to this machine and consequently *it is not a hand roller*; neither does he give the great cost of this machine: why not TELL EVERYTHING?

SEEDLESS BREADFRUITS, &c.—At a Meeting of the Committee of the Agri-Hortieultural Society of Madras, on Tuesday, the 11th November, 1884, the receipt was acknowledged of a Wardian case containing eight plants of a seedless variety of *Artocarpus incisa* (Bread-fruit), twelve of *Castilloa elastica*, three *Hevea Braziliensis* and three *Nopalea coccinellifer*, from Dr. Trimen, Director, Botanical Gardens, Ceylon. Also nine hundred and ninety seeds of Maragogipe Coffee, from Messrs. J. P. William and Brothers, Planters and Merchants, Ceylon. Read letter from Dr. Trimen, dated Peradeniya, 16th September. 1884, advising dispatch of the Wardian case acknowledged above, which was received in splendid order, on 4th October. 1884. Read letter from Messrs. J. P. William and Brothers, dated Heneratgada. Ceylon, 8th October, 1884, advising the despatch of the one thousand seeds of "Maragogipe" Coffee acknowledged above as a present to the Society, stating that they have supplied similar seed in large quantity to several planters in Java and elsewhere, and enclosing some memoranda on the subject including the following:—"It appears that the shell of the Maragogipe Coffee bean is of a more delicate nature than the other varieties of Coffee. The seeds require careful treatment In preparing the nursery the soil should be well pulverized about one, or one and half foot deep. The top of the nursery, about one and half inch, should be filled with a mixture of two parts soil and one part powdered charcoal. Cover the seeds lightly about half inch, shade, and water twice a day, morning and evening; all other treatment same as for Arabian Coffee. If the soil is poor, mix well decayed cowdung manure, ¼ manure to ¾ soil. Seeds will germinate in 5 to 7 weeks, germination complete in 12 weeks." Recorded with the best thanks of the Society.

* This is not fair: "Peppercorn" did not run down Indian men, but alleged that there was a fair prospect of Ceylon men going ahead as inventors and doing better, and that is what we all hope for and expect.—ED.

COFFEE LEAF DISEASE AND THE INFLUENCE OF SHADE.

Some time ago the *Ceylon Observer* copied a paragraph from a Java newspaper in which a correspondent attributed leaf disease in coffee to the practice of planting Erythrina trees for shade, and asserted, firstly, that leaf disease has been known since 1840, and secondly, that where coffee has been planted in forest land, or where Erythrina trees are not used for shade, the disease does not exist. These statements were not editorially endorsed, and have attracted little or no attention in Ceylon. Mr. Wilson, the Director of Revenue Settlement and Agriculture in Madras, with a praiseworthy desire to collect all available information on this important subject, has had the paragraph reprinted, and circulated with a view to discover whether the theory advanced therein has any foundation in fact. As the origin and nature of the parasite, *hemileia vastatrix*, which causes leaf disease in coffee, have been investigated by some of the first botanists of the day, who were specially brought out to Ceylon for the purpose, so simple an explanation as the neighbourhood of the Erythrina could hardly have escaped their notice, and as a matter of fact, there does not appear to be the slightest ground for the assertion made by the writer in the *Java Bode*. In the first place Erythrina is hardly ever planted for coffee shade in India, and where it has been so employed leaf disease does not appear to be worse than elsewhere, while it most certainly exists far from the neighbourhood of these trees. Then again, in Ceylon, where in the present day one can ride through miles of once flourishing estates now devastated by leaf disease, neither Erythrina, nor any other shade tree is visible, it having been a cadinal article of faith with planters there,—in former days at least,—not to leave a single stick standing amongst their coffee. Besides these two tolerably conclusive arguments against accepting Erythrina as the cause of *hemileia vastatrix*, it must be remembered that this pest is closely allied to the phylloxera,* which has nearly destroyed all the vines in France; and the phylloxera most certainly cannot be attributed to the Erythrina which does not exist in or near the vineyards.

The origin of the leaf disease in coffee, like that of the potato blight, and of the vine disease, is still a subject of dispute, and the conflicting theories of scientific men as to a remedy for it have been of little practical use to planters. It has been attributed to poverty of soil, to absence of shade, to want of proper manures, and to a variety of other causes. Planters who can remember its first appearance in India, relate that when its ravages first began to attract attention, many men declared that it was no new thing, but that it had been known for years in a less virulent form. It is certainly a fact that the exact date of its appearance can hardly be fixed. The only indisputable thing about it is the amount of damage it has caused. It has shortened the life of the coffee trees, it has reduced their bearing powers to less than half, and it has seriously injured the quality of the bean. It seems very probable that the *hemileia vastatrix* originally existed in the jungle, and only descended on the coffee trees when the continually spreading encroachments of the planters deprived it of its natural *habitat*. A fact which supports this theory is, that in Mysore the original coffee plantations, which were all opened under heavy forest shade, enjoyed a practical immunity from leaf disease during many years, while other parts of India were devastated by it; but when Ceylon ideas of cultivation extended to Mysore, and all extensions were made by entirely clearing away the forest, the new estates were almost immediately attacked, and have suffered terribly ever since. The only remedy that has hitherto availed in combating leaf disease, where it has once established a footing in a district, is the systematic and early planting of shade trees, such as jak and fig, which experience has shown to be suitable for the purpose, combined with a high standard of cultivation. The first of these remedies is easily and extensively applied, and merely requires the coffee nurseries to be made larger so as to contain the shade seedlings; the last, of course, involves a heavy expenditure for manure, and especially for cattle manure. It seems possible by these means to extirpate leaf disease, or rather perhaps it should be said, to bring the coffee trees into such a healthy condition as will enable them to withstand the attacks of their enemy. It is also, unfortunately, easy in these days of low prices to cultivate an estate beyond the possibility of profit, and planters often find themselves with no choice between omitting important work that would, if completed, enable their coffee to pull round after a heavy crop, or else spending more money than a strictly commercial view of their position would warrant them in doing. In Ceylon cattle manuring has been almost entirely given up except on estates where unusual facilities for it exist, such as the neighbourhood of a village, where the manure can be obtained cheaply, and in large quantities. Various artificial manures have been tried with a great deal of temporary success, but though these, in some cases, contain exactly the substances that chemistry proves to be required to recuperate the coffee plant, experience shows that in lasting qualities at least, they are none of them equal to animal manure; they, however, command much popularity on account of their cheapness, the most expensive of them not costing half as much for purchase and application as the other. A perfect manure for coffee, that would combine the lasting qualities of cattle manure with the cheapness of the artificial manure, has still to be discovered, and the subject is one that might with advantage to the community be taken up by Government. With regard to a cure for leaf disease, however, so many experiments have been made in this direction, and so many remedies, confidently advertised as perfect, have proved worthless, that planters have almost given up speculating on the subject.—*Madras. Mail.*

* They are allied only by the fact that both are destructive pests. Phylloxera, the enemy of the vine, is an insect; *Hemileia vastatrix*, so fatal to coffee, is a fungus.—ED.

JAPAN TEA AND TOBACCO.

Mr. John Hughes, Agricultural Analyst, writes to us:—"I enclose you an article in Japanese Tea and Tobacco published in the last number of the *Chemical News*. It goes perhaps rather more into analytical details than you require for the *Tropical Agriculturist*, but, as you will notice from a cutting from the *Field* sent herewith, this monthly magazine is becoming quite a recognised source of all information upon Tea and other colonial production. It will be for you to say how much of the article should be published."

The article referred to is doubly interesting as being from the pen of a Japanese chemist, for "J. Takayama" is clearly a native of Japan, who has received a western education. From the account this gentleman gives, it is evident that in the preparation of Japan tea, all ordinary principles of tea-making are violated, the green leaves being steamed (!) instead of being rolled on tables or in machines. Most astonishing of all the tea is dried over furnaces in boxes with paper bottoms. The paper which withstands the furnace heat must be peculiar. This refers to the Oolong tea of Japan which is so great a favourite in America. Black tea, the manufacture of which has been only recently introduced, is evidently regarded as an inferior article, being made from the leaves of "wild" (?) or badly cultivated tea bushes. Even in regard to this tea, rolling, as we understand it, does not seem to be resorted to, only tossing and clapping between the hands. We copy the articles referred by Mr. Hughes, all except a table of figures referring to the constituents of teas from different districts. The highest total extract is so good as 45·21 per cent, while one specimen gave 5·37 of nitrogen. The highest total of soluble organic matter is 41·87. The percentage of ash is however low.

ON JAPANESE TEA AND TOBACCO.

BY J. TAKAYAMA.

The tea-leaves are gathered in May, and quickly dried by exposure to air, and carefully sifted so as to separate dust and fragments of leaves. They are then subjected to steaming. This is done by introducing the leaves into a wooden tub, the bottom of which is formed of bamboo meshes, the tub being placed on an iron pan filled with water and heated from below. After thirtyminutes, when

the steam rises up, the wooden cover is taken off, and the contents are thoroughly mixed so as to steam uniformly all the leaves. This done, the tub is covered again with the lid This process is repeated, and finally the contents are taken out and couled. There is a tendency in leaves to adhere to the bamboo rod during mixing.

The leaves are now sufficiently softened to be rolled up between the hands by a gentle rubbing, after which the leaves are subjected to drying. This operation is a most difficult one, inasmuch as the quality of the product depends in great measure on the treatment which the leaves undergo during the operation, since it is during drying that that fine colour becomes fixed, with simultaneous production of that delicate flavour and agreeable taste which are wanting in the original leaves; so that it requires excellent workmen, whose requisite skill is only attained after a long practice.

The dryiog is conducted in a shallow rectangular box, the bottom of which is made of a thick paper stiffened with starch. The box is placed over a copper-wire gauze supported by iron bars, which are provided across the furnace. The furnace is simply a rectangular box coated with clay, and has the depth of 2·5 shaku.

To begin the operation, first of all a charcoal fire is made in the furnace. The rectangular box is now placed over it, the leaves are next introduced into the box, and the workman continually rubs them between the hands, alternately tossing them up and letting them fall until they are nearly dried. Thus dried the leaves are further dried by keeping for a night in the same furnace after the charcoal fire is withdrawn. In large factories numbers of these furnaces are arranged in rows, and during the drying each furnace is attended by one workman.

The tea thus dried is, before it is sent to the market, subjected to sorting and sieving. The sorting simply consists in spreading out a certain quantity of tea upon a flat table, and in removing dust, stems, and other foreign matters by picking them up, which operation is usually done by women and girls. The sorted tea is then sieved.

The sieves of different meshes are distinguished from one another by the numbers 1, 2, 3, &c., and the number of sievings as well as the sieves used vary with the quality of the tea. Thus, in the case of coarse kinds, it is passed twice or thrice through each of 1 and 2, and in the best kinds only once through 2, 3, 4, and twice through 3, which has the meshes of nearly 3 millimetres. The tea thus prepared is preserved in earthenware or metallic pots in order to preserve it from the moisture.

BLACK TEA.

Before intercourse with Western nations was opened this was scarcely known to us, but now at present it is manufactured, though to a very limited extent, for the purpose of exporting it to foreign countries.

The writer states the following description of the process to be due to the Report published by order of the Board for promotion of industry, agriculture, and commerce.

In preparing the black tea, the leaves from wild tea-plants, or those which are cultivated without much care, are used, otherwise there will not be much profit.

The leaves after gathering are scattered on a straw mat, and dried by exposure to air. They are then collected and softened by tossing and clapping between the hands till they become adhesive. The leaves are then made into a number of balls, which are introduced into a large box, which is closed tightly and exposed to the sun for half an-hour, when it is brought into the house, and allowed to lie in this state for one night. The balls are then taken out, and subjected to the rolling and drying in the same way as in the preparation of green tea. During the operation the workman turns the mass, so as to prevent it from being burnt. This process is continued until the leaves break very easily by simply pressing between the fingers, when they are considered to be perfectly dry. The tea thus produced is freed from impurities and stalks, and separated into different kinds by passing through sieves having meshes of different size.

The specimens he chemically examined are all those prepared in the celebrated tea-producing district Uji, and are supposed to be unadulterated.

The accompanying tablo gives the result of the analyses. On oxamining the table there seems to be no connection between commercial quality and chemical composition, but it is very interestiug to observe how nearly the same st the amount of the constituents in all specimens; so that, in any instance, if we find some of the constituents aa ash, for instance, in quantity differing from those found in the table, we may consider such specimen as being previously adulterated.

Nitrogen in the table was determined by Dumas's method.

Theine.—He estimates this most important constituent of tea by the following method:—15 grms. of powdered tea are mixed with an equal amount of magnesia, and the mixture is boiled with water, filtered, and residue washed with hot water. The filtrate being evaporated to dryness is exhausted with hot benzole, and the extract is then evaporated and the residue is weighted. By this method he found 0·189 per cent in *Nagauotomo*, and 0·207 per cent in *Horiu*, all brought from Uji.

ANALYSIS OF TEA ASH.

	Green Tea from Uji.		Black Tea from Settsu.	
	I.	II.	III.	IV.
Silica	8·91	6·19	5·01	4·61
Sulphuric acid...	3·87	4·70	3·03	4·22
Phosphoric acid	16·62	17·02	21·87	19·77
Chlorine	1·62	1·95	1·26	1·04
Carbonic acid	7·82	9·45	6·23	7·02
Oxide of iron and alumina ...	8·21	9·06	6·35	7·96
Manganese sesquioxide ...	0·59	trace	0·98	1·30
Lime	14·57	13·17	8·33	10·42
Magnesia	6·95	6·17	6·92	7·00
Soda	2·70	4·03	5·01	2·99
Potash	27·92	28·11	35·04	33·60
	99·78	99·86	100·03	99·93

Tannin.—This is determined by a standard solution of plumbic acetate. In six specimens from Uji he found the following amounts:—Toyonokumo, 16 per cent; Toyokague, 16·25 per cent; Shimonohana, 15·62 per cent; Nagauotomo, 14·70 per cent; Toyomaye, 16·70 per cent; Hochayen, 16·12 per cent.

Gum.—Estimated by evaporating the aqueous extract of tea almost to dryness, treating the residue with methyl spirit, the extract evaporated to dryness, and the residue weighed, which, after ignition is again weighed; the loss represents the gum. By this method he found the following amounts in the same specimens as above:—Toyokumo, 13·72 per cent; Toyokage, 9·75 per cent; Shimonohana, 12·32 per cent; Nagauotomo, 10·10 per cent, Toyoumaye, 9·90 per cent; Hochayen, 10·61 per cent.

JAPANESE TOBACCO.

There were various varieties of tobacco plant, differing more or less in the form and size of the leaf, but those growing in this country are known as *Nicotiana Chinensis*, and *Nicotiana Tabacum*, bearing rose-coloured flower, and growing to the height of 3 to 5 feet. The tobacco plant is cultivated almost in every province, but the best leaves are produced in the provinces of Hizen, Hitachi, Satsuma, and Nagato.

The mode of collecting the leaves varies in different places, but generally two or three small leaves, which are situated at the upper part of the stem, are first taken off by hand, and the remaining leaves, after being exposed to the sun for 3 to 5 days, are successively taken, three or four at a time. In Awa it is just reversed; the lower leaves, which are of inferior quality, are taken off at first in June, when the leaves are slightly yellowish, and the middle leaves, which form the best sorts, are collected after 13 or 14 days. In some places a second crop is obtained from new shoots, which, if properly cultivated, yield leaves which are not inferior to those of the first gathering.

The leaves thus collected are placed on a floor covered with a straw mat, allowed to remain for one or two days, when the mat is taken off; those which have assumed the melon-yellow colour are sorted out and dried by exposure to air, while those still retaining the original colour are kept in the same condition till the required colour is developed.

The dried leaves are now packed and sent to market. According to Japanese fashion, tobacco for smoking purposes is cut into fine threads.

THE ROOT.*

Introducing the subject, Mr. Ward requested his audience to dismiss expectations or apprehensions of marvellous descriptions of tropical or rare roots on the one hand, or lists of the peculiarities of various kinds of roots, or so-called roots, on the other. The object was to show, as well as time permitted, how much valuable information could be derived from careful study of a common root, and that this information is important alike to botanists and agriculturists, as is so much other which they have in common.

The germination of a seed was then shortly described and fully illustrated (as was the lecture throughout) by diagrams, and showed that the young root proceeds to enter the soil to fulfil the purposes for which it has become adapted—viz., to hold the rest of the plant, and to absorb water and dissolved food matters in the soil. The curious properties of the tip of the root were then examined. It is sensitive to various influences, turning towards the centre of the earth with marked persistence. It also avoids the light and tends towards a moist surface; but, strangest of all, perhaps, are its sensitive actions towards solid bodies and irritants, and its curious rocking movements. Some time was employed in shortly describing these matters, and showing how they probably aid the tip to enter the soil.

The structure of the firm, rigid, and even elastic tip, and its protective cap, was then sketched, stress being laid on the fact that such a body could not possibly serve as an absorptive organ, but that it is admirably adapted for being steadily pushed between the particles of soil, aided by its guiding sensitiveness to various influences, its tendency to slightly rock on all sides, slippery surface, and conical shape. The elongation of cells behind pushes this tip slowly and steadily forward with relatively enormous force. This point explained, the lecturer then proceeded to show how root-hairs arise in millions on the parts which have ceased to elongate—an obvious adaptation, which prevents their being rubbed off as the rest of the root moves forward.

A still more beautiful adaptation to the same end was shown in the origin and development of the rootlets, which arise beneath the surface of the elongating roots, to come out when the part has ceased to move forwards, hence employing the time but avoiding the danger. The efficient distribution of root-hairs and rootlets was commented upon, showing how every crevice of the soil is successively explored from the central roots, the rootlets reacting differently as regards gravitation from the primary root. The mode in which root-hairs attach themselves to particles of sand, slate, &c., in the soil, glueing themselves to their surfaces, was described, and then Mr. Ward shortly explained their action in absorbing the aërated water and its dissolved salts.

The clear evidence of adaptation in structure and function to the environment was touched upon; the author pointing out that the historical matters here concerned, and the comparison of a large series of forms would take several lectures, but would be quite conclusive as to the struggle for existence which roots have undergone before they earned their present rights as dwellers in the land.—*Gardeners' Chronicle.*

* Abstract of a lecture delivered before the Manchester Horticultural Society, November 6, 1884, by H. Marshall Ward, M.A., Assistant Lecturer in Botany at the Owen College.

FOREIGN FOREST PRODUCE.

Woods and forests seem attracting especial attention this year. In the report on the Russian forests, the various kinds of trees found in the country are treated of rather fully, and the limit of each kind given in detail. Under the head "Industries in Wood" some very interesting facts are recorded; thus in referring to carriage and cart building it is stated that a vehicle is seldom finished off on the spot: one village will provide the spokes for the wheels, another the boxes, another will make the body for the cart. Another great industry is that of wooden spoons, of which about 126,000,000 are annually made. In the same way are the spoons finished off: one will cut the wood into lengths, another shape the spoon in the rough, another hollows it out, and at last it passes into the hands of the varnisher. The spoons are generally made of Birch, Poplar, and from the dust of Boxwood. One cubic fathom of wood makes about 4,000 spoons; a man can make 180 in a day. The average price per 1,000 is from 6 to 8 roubles, and about 3,200 cubic fathoms of wood are annually used for this purpose. They are exported, *via* Tibet, to Khiva, Bouchara, and *via* Astrakan to Persia.

Yokes are mostly made in the Government of Kazan, of Elm and Willow. Three workmen in a family are calculated to produce from 700 to 1,000 in the course of the winter. From the bark of the Alder tree a green dye is extracted, with which they are stained. Their principal markets are in Simbirsk and Samara. In Tula concertinas are made to the extent of 250,000 yearly; and in the Government of Viatka, besides concertinas, organs and violins are also made. Besides these and many other branches of industry in timber itself, an important trade is done in the bark of the Lime tree. From this material more than 100,000,000 pairs of bast shoes are made annually, each pair requiring three-fourths of the bark of a young tree. An immense quantity of bast is used also in making matting and sacks, and it is estimated that this industry considerably exceeds 2,000,000 roubles a year. In Viatka alone 500,000 Lime trees are cut down annually for this purpose, and 900,000 mats and 600,000 sacks made annually. The best matting is called "Schangskaia," and is largely exported to England. Tar, pitch, turpentine, birch oil, and charcoal are also large and important products of the Russian forests.

Under the heading "Plantations along Railways," some careful details are given of the extent to which this has been carried, with the object of protecting the track from snowdrifts. On the railways where it has been tried it has been very successful, so that it is proposed to carry it out more generally. Seven rows of plants have been the rule, some of trees and some of shrubs. The following plants it seems have been most successful:—Elm, Ash, Oak, white and yellow Acacia, Lime, Maple, Whitethorn, Elæagnus hortensis, Hazel, wild Plum (Prunus spinosa), Gleditschia, Mulberry, Amorpha fruticosa, Ligustrum vulgare, Sambucus, &c. These have for the most part been planted in an unfruitful soil in dry exposed places, but have nevertheless done well. Along the Tunic Railway, Government of Charkoff, the Pine (Pinus sylvestris) has been planted and flourishes, and at Karlowka, in the Government of Poltava, it grows on the open steppe.

For fixing the sand plains at Aleschki, on the Dneiper, the Government has planted largely Salix acutifolia, Genista tinctoria, Ulex europæus, Prunus spinosa, and Pinus maritima.—*Gardeners' Chronicle.*

FIBRE FROM PUERARIA.—At the last meeting of the Linnean Society some cloth was shown made in China from the fibre of this plant, which was very tough and strong.—*Gardeners' Chronicle.*

BROUSSA TEA.—At the last meeting of the Linnean Society Mr. W. T. Thiselton Dyer showed a specimen of Tea made at Broussa from the leaves of Vaccinium arctostaphylos. So close was the resemblance and fragrance to that of ordinary Tea, that the customs' authorities refused to allow the sample to pass without paying the duty as Tea. The quality of the infusion was stated not to be good. Mr. Bennett alluded to the use of Ledum leaves in Canada for like purposes. It is hoped that Dr. Schorlemmer will analyse the leaves both of the Vaccinium and the Ledum to ascertain whether thein or any allied alkaloid be present.—*Gardeners' Chronicle.*

TEA IN JAVA.—A friend in Java writes that anyone going into tea cultivation there is pretty sure of obtaining a partical acquaintance with the working of the insolvency laws, *ten gevalgder zware schattingen* (in consequence of the heavy taxes).—*Cor.*

FORESTRY IN CHINA.—A correspondent of the London *Gardeners' Chronicle* says:—"I noticed that nearly every garden contained a few specimens of the Chusan Palm, Chamærops Fortunei, which the natives cultivate for the purpose of supplying themselves with fibre obtained from the sheaths of the leaves, to fabricate waterproof capes. Paulownia imperialis, with its very large leaves, was a conspicuous object in one locality, although it did not attain to more than about 15 feet in height. With the exception of some healthy young plantations of Cunninghamia sinensis, the Conifer which supplies China Fir for building purposes, I notice scarcely any tree planting operations. This is different to the case in the West River districts, where the people devote considerable care to the rearing of Pinus sinensis. The neglect of tree planting in one place, and the fostering of it in the other, is probably accounted for by the facilities of getting the wood to market, which is afforded by the splendid West River in the latter case, while in the former there is no river nearer than 8 or 9 miles to the nearest part of the mountains."—*Gardeners' Monthly.*

KITOOL FIBRE.—The Palm, Caryota urens, Linn., is a native of Ceylon, Malabar, Bengal, Assam, and various parts of India. Amongst natives of Ceylon it is known as Kitool; in India it is called Bastard Sago, Coonda pauna (Tamil); Erimpana, or Schundra-pana (Mal.). It it a beautiful and lofty palm, with a trunk more than a foot in diameter, and 40 feet high. The large bipinnatisect leaves measure 18 feet to 20 feet in length, and 10 to 12 feet across. The fruit is of the size of a plum, with a thin yellow rind, and is very burning and acrid in taste. From the flower-stem an enormous amount of sweet juice can be obtained; as much as 100 pints in twenty-four hours. From this juice Jaggery sugar well known in our markets,* is prepared, although it is not the only source, other palm trees yielding it in commercial quantities. The caste who prepare this sugar in Ceylon are known as Jaggeros. The juice is also pleasant to drink when fresh, and an intoxicating spirit, known variously as toddy, arrack, pauna, or pawnee, is obtained by fermentation, and largely used. The pith of the stem contains a large amount of farinaceous matter, equal to Sago in quality. The natives use this largely for food in the shape of gruel, or a kind of bread, Like its relative, the Cocoanut, Kitool Palm is a source of food and profit to its owner. Elephants make of the leaves their favorite food, and the "heart," or expanded leaves, can be made into a capital cabbage, or pickled, or candied. The woolly substance at the base of the leaves is used in caulking ships. The fibres or veins of the leaves furnish the Kitool fibre, and it is largely used by the natives for the making of ropes, fishing-lines, bow-strings, brushes, brooms, baskets, caps, &c. Its great strength has earned for it the name of Elephant fibre, and ropes made of Kitool are used to tether and secure wild elephants. The fibre has long been known in this country, and under the name of Indian gut has long been used for fishing-lines. When made into brushes it is found to be most durable, and some firms will not use brushes made of any other material. It seems to be the best substitute for bristles, as the fibre is strong, tough, and impervious to water. It is, however, rather brittle, and a sudden knock may break it. It can be woven together with cotton for petticoat stuffs, and forms a cheap and flexible fabric for dress-improvers, &c. Steamed and curled, it can be used for stuffing purposes in upholstery, and the refuse may be used instead of hair to mix with mortar for building purposes. When dipped in oil it turns from a dull brown to a beautiful black color, and the oiliness may be removed.—*Journal of the Society of Arts.*

* We do not suppose that a cwt. of kitul jaggery has ever been exported from Ceylon. We might, perhaps, say the same thing of coconut jaggery. That exported is the product of the palmyra palm, *Borassus flabelliformis.*—ED.

PRICES OF TEA AND COFFEE IN THE UNITED STATES.—"A free breakfast table," as far as tea and coffee are concerned, has prevailed in the United States since July 1st 1872, when the import duties were abolished. In 1871, the average price of tea per lb. was so high as 56½ to 59 cents, or close on 2s 6d. By 1883, the average price had gone down to 19 to 20 cents, say 10d. Coffee per lb. was up to 19 to 22 cents in 1874, say 11d.; while in 1882 the price was 10 cents or 5d., a fall of considerably more than one-half. The tea was good average Japan; the coffee fair Rio.

RUBBER CULTIVATION.—Whether the results at present obtained are commensurate with the outlay of skill and capital which has been involved it is extremely difficult to judge; at any rate we are still dependent on those sources of supply which twenty-five years ago were threatened to become extinct. It is true we are drawing from new sources which have been opened up, but we seem to be a long way off from getting rubber of our own cultivation. Prices are now falling, and probably will reach a figure at which cultivation may not seem a very tempting bait to intending planters. The facts just now are not what they were in 1856 to 1860 as regards rubber production. Many kinds which at that time could hardly have paid for collecting are so far improved in collection and preparing that they command a far higher price in proportion than the very best Brazilian varieties. We would strongly urge the attention of such facts on our Government Departments entrusted with this matter. Is our attention directed to this matter in a way best calculated to secure that amount of commercial success compatible with rapid production, or are we, in endeavouring to compete with the best kinds of rubber, neglecting the cultivation of those plants which give a fair and useful rubber, and which our planters may certainly improve by better methods of collecting? Manufacturers are deeply interested in this matter. At one time Para, Negrohead, Ceará, and Guayaquil rubbers were indispensable. The opening up of the interior of the African continent has already improved our supplies, and we are afraid that unless more encouraging results are not shortly forthcoming in favour of cultivation, growers are not likely to make such grand things by raising crops of rubber plants where other colonial products can be successfully planted.—*Indiarubber and Guttapercha Journal.*

DEATH & ELLWOOD'S FIBRE MACHINE is thus noticed by Mr. W. A. Cogswell, President of the Horticultural Society of India:—The only machine, to my knowledge, which has yet approached to what is desirable, nay, absolutely needful, is that known as Death & Ellwood's, Smith's Patent, Fibre Extracting Machine, which I have had the privilege of seeing in work recently. It is called the Universal Fibre-Cleaning Machine, and is simple and strong in all its parts. Like some other machines for the same purpose it consists of a drum on which metal beaters are bolted, the drum revolves at a great speed in front of an adjustable plate fixed below its centre, so as to give a scraping action to the fibre which is fed in by hand, over the plate. Immediately below the plate a jet of water is forced which, while washing the gum and mucilaginous matter from the fibre and ridding it of particles of stalk and other foreign matter, forces it up against the drum and thus keeps it subjected to the action of the scrapers, and it is in this the success of the machine lies; unlike others it has an *elastic* bed of water, instead of a rigid one of wood to support the fibre while under treatment from the scrapers. The price of a single machine without engine is £55. The original outlay, the cost of working and maintaining it would, however, be prohibitory to a ryot, but a Company might be formed to establish its use in the Jute growing districts, to purchase the plant, when it was ready to cut in the season, from the cultivator, and such a Company could prepare and completely make ready the fibre for sale in the open market. The native cultivators have not the money to spend in purchasing, or maintaining in efficient working order any machine, no matter how desirable and thoroughly good that may be, and I am of opinion that such must be first introduced to the growers in the way which I have suggested. I success is to attend their working.—W. H. COGSWEL

COST OF THE MANUFACTURE, TRANSPORT, ETC., OF CEYLON TEA.

The latest contribution which Mr. Rutherford has made to the literature of the tea enterprize in Ceylon is specially valuable, because of the considerable quantities on which the deductions of comparative cost are founded and the evidence of conscientious care with which the results have been arrived at and stated. The comparisons instituted, it will be seen, embrace tea prepared entirely without machinery; tea prepared partially by hand and partially by machinery; and tea prepared entirely by machinery. The results are less in favour of the direct saving in cost of manufacture by machinery as against primitive modes and appliances, than were previous statements by Messrs. Armstrong, Owen and others; but, taking into account all the circumstances, including a defective water-power, where that power was applied, and remembering the fact that in most cases neither rolling nor drying machinery used come up as yet to the performances claimed for them by their inventors, the direct saving established by the use of machinery is satisfactory. But, as Mr. Rutherford so justly remarks, we have to take into account the large *indirect* advantages secured by the use of good machinery: first and foremost the great saving of human labour and generally a better and more equable quality of tea made. The highest direct saving shown by Mr. Rutherford as secured by the use of rolling and drying machines (sifters do not seem to be taken into account) is 3½ cents per lb., as against Mr. Armstrong's estimate of 6⅛ cents, Mr. Owen's of 6½ Mr. Hay's of 5½ and other calculations of 4·67 cents and 4·75.

The authors of the estimates referred to may probably now be able to give the results of more extended experience and with different machines. It will be seen that the machinery used on the estates in which Mr. Rutherford is interested are Kinmond's rollers and driers, Sirocco's of the old type and Thomson's "Challenge" hand-power roller. Other items besides manufacture, as enumerated, being taken into account, the average total cost free on board in Colombo of the teas from the estates treated of is given at 17·60 cents per lb. instead of, say, 20 cents, which would probably have been the figure had no machinery been used. Such being the case, 15 cents would not, perhaps, be too low a calculation for the manufacture and conveyance to the steamer in Colombo Harbour (a work which gives the tea planters low freights), where circumstances of water power &c. are favourable. Perhaps correspondents, good at figures, will add to this sum of 15 cents per lb. the cost of growing the tea up to plucking point, and the dock, brokerage and other charges in London up to the sale of the leaf and the realization of the price paid for it. Typical cases might be taken, from estates near Colombo with the great advantage of excessively cheap water carriage (so low as 30 decimals of a cent per pound in one case!) to those near Nanuoya which have to pay 1·85 cent per lb. and others in distant Uva which must disburse two or even three cents per lb. But we must not forget that the present excessive charges on the railway beyond Nawalapitiya are sure to be considerably reduced at an early date.—As an average for tea picking, we believe Mr. Rutherford's figure of 13 lb. per cooly to be much nearer the mark (as an *average*) than the Indian rate of 16 lb. as specified by Col. Money.

While we are waiting for definite information, as to the average whole cost of a pound of Ceylon tea, up to the period of sale, shall we be wide of the mark if we double the 15 cents, which represent cost, from plucking to packing and placing in the hold of a steamer for London, and say 30 cents?

An average of 60 cents per lb. would, after clearing London charges, mean 50 per cent profit, or R150 per acre where the yield averaged 500 per acre. If we are at all near the mark with our 30 cents per lb. total cost, we suppose it will be admitted that there is a good margin for reduction of selling price, and we suppose that even if value in the London market went down to an average of 10d per lb. tea growing in Ceylon would still pay?

CEYLON PLANTERS' ASSOCIATION; VALUABLE INFORMATION ON THE COST OF MANUFACTURE, TRANSPORT, ETC., OF TEA.

Planters' Association of Ceylon, Kandy, 27th Feb. 1885.

Sir,—I beg to enclose for publication an interesting and valuable letter received from Mr. H. K. Rutherford on the cost of tea manufacture &c.—I am, sir, yours faithfully, A. PHILIP, Secretary.

Watawala, 20th February 1885.

The Secretary, Planters' Association, Kandy.

Dear Sir,—Since Messrs. Armstrong, Hay and Owen and others in the latter part of 1883 gave to Ceylon planters much valuable information regarding the cost of producing tea, I do not think the details of the cost of manufacture have been again brought up in the local papers. I have much pleasure in sending you the following figures showing the actual cost of considerable quantities of tea made on four gardens with which I am connected. The saving by machinery over hand-work, I do not find to be so great as was stated by the abovenamed gentlemen in 1883, but I have no doubt they are now in possession of much further data than they had in those days and will be able to give their later experience of the saving effected by machinery. As far as I can gather, the following were the estimates given of the saving that would be effected by the use of machinery:—

			Cents.
24th Aug.	1883	Mr. Armstrong gives saving at	6·34
15th Sept.	,,	,, Owen 7 cents afterwards modified to	6·50
12th Oct.	,,	,, Hay (Gallebodde data)	5·50
19th Oct.	,,	"Adam's Peak"* ,,	4·67
23rd	,,	,, "Proprietor"* ,,	4·75

* Newspaper correspondents.

From the following figures, it will be seen, the most favorable result obtained was a saving of R3·25 per lb. where steam-power was used.

With perfect water-power the saving might be increased to 3·50 cents, but I am of opinion a greater direct saving cannot be obtained, although, of course, the indirect saving and advantages by using machinery are very great, so as to make its application a necessity on almost all gardens.

I beg to suggest it would be exceedingly useful and interesting if you could collect information from others as to cost of manufacturing tea by other machines than those stated below, so that comparisons could be made. As many estates are making large quantities of tea, accurate data ought now to be available. Previously we had to be content with assumptions worked out on the quantity a cooly or a machine could roll and fire per hour; but, to arrive at anything like accuracy, fairly large quantities must be dealt with, and, if possble, a whole season's yield.

I think the Planters' Association ought to be the means of collecting all information of this nature. It is not at all necessary that those affording the information should state the name of the garden the results are obtained from, but I think the quantity of tea on which the data are based should be given.

Cost of Rolling and Firing Teas by Various Methods.

Process.	No. of lb. made tea.	Labor on withering, rolling and firing.	Charcoal and firewood.	Total.	Saving over hand-work.	
		c.	c.	c.		
Hand-rolling and firing over chulas	201,964	4·11	0·87	4·98	...	*
Hand-rolling, firing with chulas and Siroccos of old type ...	103,042	3·82	0·38	4·20	0·78	†
Rolling: hand-power Challenge; firing with chulas and Siroccos of old type ...	44,070	2·32	0·38	2·70	2·28	†
Rolling No. 2 Kinmond roller, and drying with No. 2 driers & chulas: *water power very imperfect* ...	95,652	1·45	0·31	1·76	3·22	‡
Rolling No 1 Kinmond roller and drying with No. 2 drier: steam power ...	118,362	1·45	0·28	1·73	3·25	§
Total ...	563,090 lb.					

* Average of 4 gardens. † 2 gardens. ‡ 1 garden—the saving shown would have been greater, had water-power been sufficient. § 1 garden.

The other items of cost in manufacturing this quantity of 563,090 lb. of tea were as under :—

Average of Four Gardens.

	Cents.
Plucking, including baskets and transport to factory	10·31
Sorting and packing	0·53
Boxes, lead, solder and hoopiron ...	2·80
Transport to Colombo, charges f. o. b. ...	1·75
Tea-house sundries	0·48
	15 87

One Garden.

Cost of rolling and firing, if done by machinery	1·73
Total cost of manufacture f. o. b. Colombo	17 60

Certain gardens are worked for less than this, but I give these figures as the average results of four gardens, and I think in this form they will be more useful to planters than if I had singled out one particular estate. The cost of plucking is at variance with the rate which was given by many writers on the subject in 1883, when it was put down at 7 cents per lb The average of 10 31 cents is arrived at on two and a quarter million lb. of green leaf plucked over fields varying from 1¾ to 6½ years old. At 10·31 cents per lb. of made tea, this is equivalent to 2·57 cents per lb. of green leaf, or at an estate average of 33 cents would give a plucking of about 13 lb. per cooly.

The following tables may be found useful to tea planters, and you are at liberty to make any use you like of the information herewith sent you.

Tea Transport.

Railway freight on Tea per lb. calculated on a basis of 1,680 lb. of tea to a ton of gross weight:—Kalutara to Colombo ·20c; Peradeniya ·70c; Kandy ·74c; Gampola ·78c; Wattegama ·82c; Nawalapitiya ·86c; Matale ·92c; Galboda 1·04c; Watawala 1·18c; Hatton 1·37c; Kotagala 1·44c; Wattegoda 1·66c; Nannoya 1·85c. From Patupowla, Kalutara, by canal to Colombo ·30c per lb.; from Yatiyantota by river ·56c per lb.

Ocean Freights and Insurance.

1 Ton of shipping = 50 cubic feet.—an average of 917 lb. of tea. Cost of freight per lb. of tea in cents = freight in shillings × ·067 cents. Insurance at 1s 3d per lb. value; cost of insurance per lb. of tea in cents = shillings per £100 × ·038 cents.

Freights. Rate per ton. s. d.	Per lb. tea. cents.	Exchange at 1s 7½d.	*Insurance.* Per £100 s. d.	Per lb. tea. cents.
25 5 ...	1·67		10 0	0·38
27 6 ...	1·84		11 0	0·42
30 0 ...	2·01		12 0	0·46
32 6 ...	2·18		13 0	0·50
35 0 ...	2·34		14 0	0·53
37 6 ...	2·51		15 0	0·57

—Yours truly, (Signed) H. K. Rutherford.

TEA CULTIVATION IN CEYLON:

EXTRACT FROM A REPORT OF MR. JAMES IRVINE ON TEA CULTIVATION IN UVA.

Tea.—There is no longer any doubt as to tea growing freely and remuneratively in most districts of Ceylon, but it has been objected that the climate of Uva is too dry and the rainfall not so equally distributed as to give a continuous flush, and that the heavy flush during the growing season would not give a sufficient return per acre to be remunerative. It has also been urged that fuel cannot be obtained in sufficient quantity or at a price which would leave a profit on the crop. Difficulty and cost of transport for boxes, lead and other requisites up and tea down, has also been urged against the district: these objections can be easily met so far as this estate is concerned. Climate and soil, it is true, are dry in some parts of the district, where the droughts are long and continuous and heated air from the Bintenna country so bakes the soil and scorches all vegetation at certain seasons that tea would prove a hopeless speculation; but, on the other hand, a large portion of Upper Uva is peculiarly adapted to the cultivation of tea both as to soil and climate. The soil is deep, generally more or less ferruginous and retains moisture, the lower strata being very much broken and disrupted. The soil possesses natural drainage and is never sloppy even in monsoon weather. During the cold but wet months of December and January and the dry cold month of February, vegetation almost ceases, giving the trees a rest and admitting of heavy pruning, the result of which will be heavy flushes in March, April, May and June; a light pruning during the dry hot months from the middle of June to the middle of August will cause the tea again to flush with the first of the monsoon rains. The tea bushes will rest twice a year between the monsoons, giving from three to four months for one full pruning and one light pruning, and say eight months for crop. Cultivation as now carried out on the Kandyan and other estates will have to be modified to suit the climate. Of one thing I am quite convinced: that Uva will assert its superiority as a tea-growing district just as much as it has proved superior in soil and climate for coffee. It will be found first that with proper cultivation Uva tea will, under favourable circumstances, give the maximum yield of tea per acre; second, that the quality of the tea produced will be the

finest on the island, and that the tea-plant will be more durable and lasting under constant pruning and heavy plucking. These are strong assertions to make, so I shall give reasons for them: first, I have seen tea on many estates in Uva, so far back as 24 years ago, up to the most recently planted from good China tea to a first-class jât of Assam hybrid and grown at elevations from nearly 7,000 feet down to 2,500 feet, and at these different elevations I have seen the finest hybrid cattied down after running wild and grow up better than ever and flush freely. I have for years watched the China tea in the Government Gardens at Hakgala, where it actually killed out the natural growth of the soil, and when cattied down and cleared up, gave enormous flushes of fine tea. I have myself done the same at lower elevations, where on one estate I cultivated a patch of China tea till the proprietors instructed me to root it out and plant coffee: in all these cases the growth of the tea was enormous, and anyone who has had the experience of coffee on both the Kandyan and the Uva estates as I have had must know that the flush of wood thrown out on really good Uva coffee is larger, quicker in growth and more succulent than anything to be seen on the Kandy side, and it is the same with tea.—There will always be found exceptionally fine estates all over the country as we have had exceptionally fine coffee estates.

As for quality my reason may not appear quite so plain, as no Uva tea has yet been thoroughly tested or placed on the market, but my reasons are also based on fact. The soil of Upper Uva is principally composed of decayed gneiss and felspar in a very rapid state of decomposition, so much so, that it is quite common to see the patana, and even whole hill-sides, sink or subside as if undermined. It is the rapid decay of these rocks which gives our soil its great fertility, felspar in particular abounding in potash. Most of our available land has little humus or vegetable matter left, but all the mineral constituents most valuable for the tea-plant are found in abundance in the soil: this combined with the peculiarly rapid and succulent growth of the plant and wonderfully fine climate for gathering, withering and fermenting, the tea produced must be fine and as I have already said probably the finest tea in the island; the necessary good machinery and skilful management will not be found wanting. Transport and fuel are the real difficulties with which the Uva tea planter will have to contendr. Transport has always been our Uva difficulty, and our standing grievance, but we are not so badly off in this respect as we were when coffee paid well, with the good trunk roads intersecting the country from Ratnapura to Batticaloa, from Nuwara Eliya to Badulla and from Haldummulla to Hambantota. We are well supplied with main roads and the outlying estates will have most difficulty; tea packages will not stand the rough treatment and long exposure our coffee receives without serious injury, and proprietors will have to road so as to admit of their produce being loaded on the estate. * * * *

Uva can never be content till the railroad is brought to Badulla, and so far as freight to be carried is concerned, at the present rate of progression I will allow five years when the produce of Uva will be larger than it has ever been. As for timber for boxes and even fuel this can be got from the low-country of the best description and in great abundance. The Ella Pass should be opened out, the road from Wellawaya to Passara opened up, and the road from Passara to Monaragala *via* Alupota opened up, the old Batticaloa road from Badulla *via* Ridipane to Teldeniya is already open for wood carts for the supply of Badulla, but this road should be carried further into the low-country; these roads opened up abundance of timber and charcoal for fuel, and packages can be laid down at a cheap rate for any estate adjacent to or having cart communication with our main roads—for estates more difficult of access, charcoal can be carried at a rate not altogether prohibitory; the new Forest Ordinance, however, may interfere with the burning of charcoal on waste land. As for boxes and "shooks," I have no doubt Messrs. Walker & Greig will undertake to turn them out in any quantity as good and quite as cheap as they can be sent from Colombo even by rail. All tea estates should plant up waste land with fast-growing timber trees, eucalyptus, casuarina, grevillea robusta, &c., &c; there is no difficulty in getting seed of trees adapted to every elevation. I would also point out that it will pay far better to purchase fuel from waste land and pay for its transport over good roads than to reserve valuable tea land for fuel, though this property has plenty of standing forest to last as fuel for many years and there are few estates where enough of fuel cannot be got to cure a moderate acreage of tea for some years to come till the railroad is completed when coal and coke will be available, or probably cheapest and easiest of all for transport, rock oil.

* * * * *

I must not omit in conclusion to point out that tea both from the nature of the plant and its cultivation and the foliage or leaf only being used is a far more permanent cultivation than coffee. I have heard it stated by some of my friends long resident in China that the tea gardens of the peasantry are said to be centuries old, and I believe the tea plantations of Ceylon planted in suitable localties will prove to be like the olive gardens of Southern Europe almost indestructible by age or neglect, but, to insure *general* success here in Uva, we must have the only modern means of transport, viz., a railway. Without this we will never be able to compete with districts and countries more favoured in this respect and groups of estates must be placed in direct communication with railway stations by cart roads.—

(Signed) James Irvine.

Badulla, 18th Feb. 1885.

TEA CULTIVATION IN CEYLON 40 YEARS AGO.

In a recent interview with a reporter of the *Ceylon Observer*, Sir Samuel Baker enquired what the commercial prospects of Ceylon were, and said he had been greatly concerned of late to hear the bad reports from the island as to coffee. The reporter told him that our planters and merchants had now put their faith in tea and were cultivating that product to a large extent and with considerable success. "Ah," said he, "I recollect the Brothers Worms in Pussellawa, they were the first to try tea. They got over some Chinese labourers and they grew Chinese tea. It grew beautifully and they made some pounds of tea. They were ridiculed by the whole colony because they were talking of tea. Everybody said: 'This is the country for coffee, it 's no use growing tea.' The Chinese then went home again, but the Brothers Worms had triumphed(and had made some tea. It was a very simple experiment, and that was 40 years ago."

SIR SAMUEL BAKER RECOMMENDS A NEW PRODUCT.

"I have just been reading the *Tropical Agriculturist*," continued Sir Samuel, "and it has interested me very much indeed. I see what immense pains Mr. Ferguson has been taking in the interests of the colony. When I was in Japan about 2 years ago I sent to my relatives at Nuwara Eliya a large quantity of the seed of the lacquer plant, and Mrs. Baker told me she has got a lot of young plants from the seeds. It struck me that this might be a new product worth growing. I am sure Mrs Baker

would be very happy to give any information on the subject. I was the first to introduce it into England. I have got large quantities in my garden. It grows to a bush about 3 feet high. It should grow beautifully on the hills here, much better than it grows in England. It is a very valuable plant: in Japan it is considered of great value. Lacquer is the juice from the bark. It is just like the indiarubber, which is the milk from the rubber tree, so lacquer is the sap drawn from incisions in the bark of the lacquer plant. I think it is a plant which might very well be cultivated here."*

A USE FOR THE JUNGLE LANDS BETWEEN BATTICALOA AND BADULLA.

The conversation then naturally led to the rubber tree and its cultivation here. "Rubber will never pay to be cultivated," was Sir Samuel's opinion; "if the Government would sell all that jungle land between Batticaloa and Badulla at 5s an acre and the whole of it was planted with rubber it would pay. I do not mean to cultivate the rubber, but just stick the trees in as jungle plants and let them take their chance. That the only way it would pay. It will never pay to cultivate them. It would be very easy to clear the chena ground and put the trees in and then just leave them to take their chance."

TEA: SMALL BREAKS.

The *Indian Planters' Gazette* of Feb. 3rd has the following leading article:—

We are not surprised to see that all small breaks are in future to be disposed of after the big breake sales are over, and it seems to us, that a good feeling in bringing this desired end about has been shown throughout by both classes, buyers and sellers. It may seem hard to some of our small factories out here that this fiat has gone forth in London, but they ought to remember that they have the remedy in their own hands in bulking their invoices. We have no doubt that any garden which consistently bulks its tea, and continues a uniform assortment throughout the season, with of course due care bestowed on its manipulation, will in a very short time have a pull in prices. Every year that passes is moulding the Indian tea trade on more strictly commercial lines. Like all young industries, a good deal was put up with, until the trade assumed the enormous proportions it has recently attained. There are, perhaps, no more enterprizing men in any industry than tea, and we feel assured, now that it is put before them in an undeniably stubborn way, that the old practices must give way to a better system; they will rise to the occasion, and it is to be hoped that during 1885 more bulking, at any rate of small invoices, will generally obtain than heretofore. It is true that up to date the appliances at hand have been of the rudest kind; but we are glad to say that those estates lately opened out cannot complain of these, as a vast amount of capital has been laid out by many firms in not only introducing skilled European labor to erect pucca tea houses, &c., but also in giving the very best appliances that engineering skill can produce in the way of machinery to manipulate the crop. We are fully aware that many small concerns labor under disadvantages, but in a great measure the managers can assist themselves. Take, for instance, factories turning out 1,000 maunds of tea, and perhaps working at only a small profit, and requiring to sell their crop sharp in order to keep down interest charges: it will no doubt appear hard to them that their teas will, if sent in small breaks, have to remain until the larger breaks are sold. To these we say, assort into fewer classes, and then they are on a par with their larger neighbours. For instance, such factories assorting into, say, four classes, Broken Pekoe, Pekoe Souchong, and Broken tea, would only be able to send down to Calcutta about ten breaks of any decent size, whist, if assorted into two classes, twenty breaks could be sent forward with better results, simply making a lower class of Broken Pekoe and Pekoe. Some may doubt this, but we are in a position to say that this is the opinion of some of the leading brokers. There is of course one drawback in assorting these, and that is, that there is perhaps a rather larger proportion of dust made. To any one who has followed the sales, however, it must be apparent that there is not the same incentive to make small leaf teas as formerly. This season what we might term whole leaf teas have sold considerably better than teas smashed up and made to conform to the China style; and if this is to continue to the end, as we firmly believe it will then the proportion of dust will not be so great as might at first sight appear. This year, too, we may remark, that for any thing like good dust, that is to say not exactly powder, the prices have been excellent, and more nearly approaching that of former years than has been the case latterly. In the coal districts in England, about ten years ago, all the dust that was made in India was easily disposed of at remunerative rates, and we see no reason why these districts and others should not still be able to take it off now, if anything short of powder is sent. A very large proportion of the drinking teas in England nowadays is simply whole leaf Indians, and we would advise our friends in small factories to bear this in mind and assort accordingly, and we feel confident that those factories would find it a paying result. There is not only a saving in assortment, but the breaks sent forward will be a sufficiently large number of chests to insure their being sampled and sold on a par with the invoices from big factories. Where, of course, factories are favorably situated in the way of appliances for bulking and sending forward large invoices, by all means let them do so; but we are writing more with a view to assist the smaller gardens. In no case should bulking be neglected, and every care should be exercised in performing it, so that dealers at home may have no chance to cavil at the way that it is done. That they will do so for a time we doubt not, but this will disappear in a year or two.

This is one of a series of articles reflecting the opinions of the London brokers, to whom, no doubt, large breaks are a great convenience. As a matter of fact, however, as far as invoices from Ceylon are concerned, the highest prices are generally paid for small breaks, divided into four and sometimes five descriptions of tea, thus:—orange pekoe, broken pekoe, pekoe souchong, broken tea, and dust.

THE DETERIORATION OF FOOCHOW TEAS.

To Mr. Thos. Fairhurst of Foochow, one of the largest tea ports of China, we are indebted for the following copy of a paper issued by the Foochow General Chamber of Commerce, 16th October 1884. It is addressed by the Chairman, Mr. John Odell, to the British Consul, and runs as follows:—

I am aware that owing to political troubles the present is not a favorable time for bringing under the notice of the native officials matters affecting the trade of the port, but the subject I now venture to address you upon is, in the opinion of this Chamber, of such vital importance both to the Native and Foreigh merchants that I would beg your earnest co-operation and assistance.

It is a matter too well known to every one connected with the trade that in former years Foochow enjoyed the reputation of producing the finest tea in the world, but that since the year 1870, the quality has steadily fallen off. As a proof of this, it is only necessary to give you th

* The Lacquer Manufactures of Japan.—Dr. Dresser contributes to the *Globe* an article on the above subject, from which we quote a few sentences:—Lacquer is the corrosive juice of a tree known to botanists as *Rhus vernicifera*, which flows from the lactiferous vessels of the plant. It is a substance somewhat resembling india-rubber and gutta-percha, but is neither soluble in spirit nor acted upon by any of the weaker acids, even resisting the action of boiling vinegar and hot acetic acid. What we know as the lacquer wares of Japan, such as trays, bowls, cabinets, &c., are generally objects formed of wood, covered with the juice of the Rhus plant. While eleven or twelve coatings of lacquer are given to the best class of work, only the first two or three contain earth dust, the latter being either pure or lacquer mingled with some finely-ground pigment. After the earthy coatings the subsequent grindings are effected by charcoal of different degrees of hardness. Thus prepared the object is ready to receive the pattern, and this it does by the figure being drawn in fine outline on a flexible fibrous paper with lacquer used as a paint

following quotations of the highest prices realized in the two seasons 1870 and 1884, for teas from a few of the well known districts:—

	1870	1884.
Suey Kut ...	@ 2s 4d per lb.	@ 1s 3d per lb.
Kaisow ...	„ 2s 11d „	„ 1s 10½d „
Sar Yune ...	„ 2s 2d „	„ 1s 1d „
Pan Yong & Hok Oan	„ 2s 11d „	„ 1s 8d „
Paklin ...	„ 2s 5d „	„ 1s 7d „
Tong Fong Tong...	„ 1s 10d „	„ 0s 11d „

These figures speak for themselves: it is not from any falling off in the demand for fine and finest Tea which is greater than ever, as can be proved by the rapid increase in the consumption of Indian teas which maintain their superiority in quality. In 1870 the quantity of Indian tea consumed in Great Britain was 13,477,000 lb. while in the year ending 31st May 1884 it had increased to 60,469,000 lb. and it must be added that the production is increasing every year in like proportion, so that it is no exaggeration to say that in a very few years, unless a great change is made the trade of Foochow will dwindle down into a small export of common congou. It is not that the taste for fine Foochow teas has gone out of fashion: on the contrary we have the assurance of the whole trade of England that, given the "*old quality*," the demand will be greater than ever, and this is confirmed by the fact that the few so called finest teas produced this season have realized on the London Market relatively much higher prices than, quality considered, were paid for teas from Hankow. A further strong proof is that in former years the Russians, who are noted for using the finest tea obtainable, drew most of their supplies from this port; now they only take Brick tea, their fine teas being sent from Hankow.

The next point to be considered is the cause of deterioration in quality, and I fear it is apparent to every one that the greed of the growers in their eagerness to produce quantity has sacrificed quality. Probably this point is more prominent this than any previous season, for not only have the native merchants produced with a much smaller amount of outside capital a larger supply of first and second crop leaf than last year, but whereas by universal consent not only in China but also in London, the quality of this season's crop supplied to the Hankow market has been declared decidedly superior to last year's the quality of the teas brought to our market has been as freely condemned, showing conclusively that the falling off of the present season cannot be attributed to unfavourable weather, but must be charged to faulty cultivation and improper preparation. We have abundant proof that the producing shrub has been allowed to grow into a tree of some 6 to 10 feet in height, and with the soil unfertilized for years it may be said to have become a wild uncared for tree instead of the tenderly nurtured plant of the past, the young leaves of which were carefully gathered, while now they are in most cases literally scraped off the tree.

What is to be the cure for this is the next point for consideration, and the first step would apparently be that the trees in the present plantations should be at once cut or pruned down to some 3 feet in height and the ground properly and richly fertilized. If the high officials would issue an edict ordering a proportion, say 5 per cent of the old trees in each plantation to be destroyed each year and new shrubs planted, it would tend very much to the improvement of quality, but the only permanent remedy will be when new gardens, where the soil is not exhausted, are planted with young and vigorous plants.

The native grower will doubtless argue that the expense will be too great and that the production will be much diminished: so it doubtless will be for the time, but if truly fine tea is produced the enhanced value will more more than compensate for the smaller supply, while if nothing is done in a few more years their whole trade will be ruined.

It appears to me that these facts are so patent that it is almost unnecessary to draw the attention of the high authorities to what must be to them a matter of the highest importance viz. the question of the revenue collected from this article alone, but there can be no doubt that unless they take up this question with the vigor and determination it so imperatively demands it will year by year steadily decrease until at last it amounts to but a tithe of the proof the present sum.

It may not moreover be out of place to remind or probably inform the Chinese authorities that Foochow teas are handicapped by heavy inland and export taxes which the more popular Indian tea is entirely free from, and that a higher standard of quality is consequently necessary to cover the revenue requirements of the native government; also that cheap as labor is in China, it cannot compete in the matter of carriage with the system of railways rapidly being developed throughout the producing districts of India. These are additional considerations which should spur them on to remove the abuses, fatal to themselves no less than to us of which we complain; and I would venture to suggest that it might be well to urge them not to forget that India is much nearer Europe than China, and that tea growing is there entirely in the hands of English planters who clearly understand the requirements of the largest tea market in the world, viz.: the capital of their own native country, and who are straining every nerve to increase the popularity of the product.

Again asking your most strenuous exertions to maintain the trade of the port.

It thus appears that a large proportion of the tea growers in the districts whence Foochow derives its supplies have abandoned their former careful and scientific systems of pruning and manuring and have allowed the tea trees to grow wild.

On 2nd December the Consul replied:—

I am happy to be able to inform you that the Viceroy has entertained your views on the matter in the most favorable light, His Excellency assuring me in a despatch, dated the 28th ultimo, that every effort will be made by the method of proclamation and otherwise to induce the growers to adopt a new system of cultivation and to renew their plantations. I earnestly hope that the steps now taken may lead to good results and be the means of retrieving the reputation of Foochow teas.

The United States Consul had previously written:—

Upon the facts presented by you as to falling off in quality &c. of tea coming down to this port, Mr. Wingate wrote to H. E. the Governor General sending also a copy of your memorandum translated. A reply has now been received saying that H. E. the Governor General finds that the facts seem to be as stated, that orders will be sent into the tea producing districts to have some plan devised for putting things in a better state, and that the growers will be notified to take more pains about planting and cultivation, "to bring in prosperity and find profits." Enclosing the Chinese text of the more important part of the reply, with translation.

TRANSLATION.—Tea is the great product of Fokien. That the steady falling off in consumption of late years is, as you say, on account of lack of fineness in quality and flavour seems to be the real fact in the case.

It, naturally, becomes my duty to direct the tea producing districts to devise some plan of setting things to right and to notify growers to bestow added care in setting out and cultivating, so as to bring in prosperity and fine profits.

Besides sending orders (in this sense) to the Commissioners and Intendants of the Fokien Board of Trade, of the Lekin Bureau, and of the Board of Provincial Administration that they in observance immediately without loss of time send (out) orders for action to be taken accordingly and report returned in reply, I therefore, &c., &c.

Let our readers fancy the Indian or Ceylon tea planters needing the motive of Government commands to cultivate their product after a proper fashion. The fact seems to be that Indian teas are pushing even the fine leaf of Foochow out of the English market.

We add what follows from the *China Trade Report*:—

THE FOOCHOW TEA TRADE.

The following translation of a Chinese circular addressed by the foreign merchants concerned in the tea trade at Foochow to the Chinese tea hongs and tea growers has been supplied to us by a correspondent signing himself G. M. C.:—

As heaven has its motion so matters affecting mankind have also their changes. Now, we, the foreign merchants, who have been trading many years in China, have come to the conclusion that tea is an important article of trade, and that before the reign of the Emperors Hsien-fêng and Tung-chi foreigners and Chinese alike had made enorm-

ous profit from this article, sometimes as much as a hundredfold; but at the present time (we find) that not only are foreign merchants unable to make any profit, but the Chinese teamen and growers also are unable to derive any advantage. Looking at the matter from a commercial point of view, we cannot say that the trade suits the times, and, in fact, it is a matter void of harmonious arrangement. If no change be made (we are afraid) the trade in this article, as it goes on, will not be much esteemed, and in future will not be worth mention.

It appears that on its arrival in England in

	1870		but in 1884	per picul.
Suey Kut tea	was sold at	Tls. 47,	only sold at	Tls. 22
Kaisow	do do	60,	do do	36
Saryune	do do	44,	do do	18
Panyong and Fok-an	do do	60,	do do	31
Pakling	do do	49,	do do	29
Tong Foong-tong	do do	35,	do do	14

It is a well-known fact that if a comparison were made of the (different) prices (of Foochow teas) with those of the other provinces from 1870 up to the present time, a period of not more than ten years, it would be found that such prices (owing to the inferiority of the tea leaves) were actually lessened every year. You may argue that times in foreign countries have lately been different (lit. recently changed), and finest tea is now sold with difficulty; but as a matter of fact, the finest teas produced in Hunan and Hupeh provinces were largely consumed, so that you cannot say it is not much in demand.

You must bear in mind that the price of Hunan and Hupeh tea has been somewhat better in recent years, unlike that of Fuhkien, which has been much lessened in past years. You may again argue that India has, owing to its yearly increase in the growth of teas, taken the place of China.

It having been ascertained that India had, in the year 1870, produced but 13,477,000 catties, and at the end of May 1884, yielded 60,469,000 catties; therefore, you can plainly see that, during the period of a little more than ten years, India made a steady increase in the growth of this article. The cause of this increase is proper management on the part of the growers, who, in fact, have made some radical changes as to the growth of the article. Now, comparing the tea produced yearly in Fuhkien with that of India, you will find that the former gives only a small proportion; that is to say, not exceeding one-tenth of a ten-thousandth part.

We have to impress this upon your mind, that Russian merchants used formerly to procure much of the finest tea from Bohea, whereas they have since changed the system and are obtaining same from the two Hu provinces, Hunan and Hupeh. They are merely procuring Brick tea in Fuhkien now; so, you can see that Fuhkien tea cannot compete with that of the two provinces named until some change is made. Should there be men among you who know enough of the evil arising from the deterioration of the tea trade, they must devise some measures and arrange that the tall trees may be pruned down and reduced to low stature, as also to cut away annually 5 to 10 per cent. of the old trees, and replace them with new ones; also to manure the trees well; and in picking the tea leaves a distinction must be made between the old and young. If such care were bestowed upon the cultivation and manuring of the trees, we have no doubt that the finest tea could be produced. Anyone when going round the plantations can see that the hill is afresh with thrifty branches. If once developed, the leaves would be healthy and the roots strong. Were good labour and manure bestowed upon the trees the colour and taste of the leaves would be perfect, and the plantation would successfully flourish. When such is done, we have no doubt the tea trade will be in the ascendant. If no measure be taken, so as to make some change in the trade, we are afraid that all the finest tea will become coarser, and its price lower; and in such case, it will not only be difficult for the merchants to make any profit, but the tea growers will also find difficulty in amassing wealth. Consequently we take the trouble to lay the above detailed circumstances before those concerned in the trade for their consideration, with a request that they will use their best endeavour to comply with the spirit of the times (lit. the proper management of the trade). Having a knowledge of the evil arising from the present state of things, they must plainly see that if proper measures be taken, the price for the best tea will be daily increased and the wish of the merchants concerned will be fully attained.

Compliance with the above request is the ardent hope of the Foreign Tea Merchants.

The following is the mode suggested for planting tea and picking the leaves.

The plan adopted by the tea growers in the Kwangtung province is to plentifully manure the trees with bean cake every year. On a plantation with an area of one mow a dollar's worth of labour and manure was spent, and before using manure, the old earth was carried away and replaced by new earth. The tree, of course, produced sturdy branches and leaves, the colour and taste of which will be perfect; in which case, they will be considered just as good as those of India, and on their arrival in London they will fetch higher prices, and the merchants and growers will be much benefited. Consequently it is to be hoped that the many growers will adopt this mode (of cultivation.)

As to the mode of picking. It is requested that the picking of the leaves will be promply made according to the time, and that the growers will by no means allow the time to pass without picking them. At the present moment, tea leaves in the Fuhkien province are usually picked after a lapse of three or four days beyond the proper time. This practice has an injurious effect, as the leaves cannot stand the temperature, hence the finest leaves become coarser, and those who wish their tea trees to produce the finest leaves will do well to pick them according to the proper time. This a matter of vital importance. At the time of picking, it is proper for you to divide the leaves into first, second, and middling qualities; when this is done, they should be placed in separate baskets so that the same should not be mixed up. We are informed that this was the practice in former times, and now why cannot they be stored in separate places? The leaves must be sieved several times, after which they should be divided into first, second and middling qualities.

Sieving will not injure the fine quality leaves; therefore we hope that the growers will at the time of picking store the same in different places.

Dated the auspicious day of the Winter moon in the 10th year of the reign of Kwang Su. (January, 1885.)

The soy bean manure is that generally employed in China. Several years ago we used a small quantity to manure a field near Abbotsford bungalow. Trenches were dug between the rows, *nilu* twigs were placed in the trenches, the manure scattered over them, and then the earth was drawn in. The superintendent states that the portion thus manured shows the good effects to this day.

PLANTING IN JAMAICA.

PREJUDICE AGAINST CURING OF COFFEE AT SEA LEVEL IN JAMAICA—THE OLD RATTLETRAP PULPER STILL USED—THE NEGRO CHARACTER—TOOLS NOT SUPPLIED BY ESTATES—THE CREOLES AS LABORERS—LOW STATE OF MORALITY—THE CLIMATE OF JAMAICA—BLUE MOUNTAIN COFFEE—"TUBS" AND "TIERCES"—WOOD FOR COFFEE CASKS—CINCHONA: METHOD OF GROWING.

Blue Mountain District, January 1885.

Dear Sir,—To continue my letter No. 2, about Coffee Planting in Jamaica, amongst other peculiarities the planter is dead against having his coffee cured at the sea-level, as in Ceylon. He believes it would take away from its color and damage its weight, he avers the mountain air gives Blue Mountain coffee its present fame in the Liverpool Market, and will not credit the fact that some of the high mountain

Ceylon brands were quite equal in color and weight to Top Mountain, Jamaica. I fancy the custom arose simply because there being no cart-roads; it would have cost much more to convey coffee to Kingston in parchment than clear and ready to be casked. As regards sea, as most of the estates are not more than ten miles off as the crow flies, I do not see how the argument against sea'air can hold good, and, as, moreover stores (works they call them here) are small and the coffee is mostly cured and kept in unventilated barbacue huts, it certainly does not get as much care as in the fine large Ceylon stores, with coir-matting floors, jalousie windows, and plenty of ventilation. As to machinery, the pulper described and used by Laborie of St. Domingo, 100 years ago, is still the only one in use on these estates, no lessons seem to have been taken from the improvements in Ceylon; this of itself is sufficient to point out how little Jamaica has advanced as compared with younger colonies. The rattletrap prevails with its heavy, solid barrel of the hardest wood procurable, its old-fashioned punch, the cumbrous heavy sieve, not driven even by a crank, but by curious heavy nobs on the barrel, which work a wooden frame attached to the sieve, and makes a loud clucking noise; so I shall be very glad when I receive the iron pulper with elevators and circular sieve from J. Walker & Co., and get a proper machine at work. As to pulping houses they are small, and as a rule the cisterns, all lead one into another, convenience and arrangement are no where, such a "laissez aller" style being quite in keeping with the negro character of lack of order and neatness. Except dressing fine for church on Sundays he seems to be careless about cleanliness and outward appearances, an old tattered suit of clothes being worn over the under one, and of course gives them a very beggarly aspect.

Another peculiarity of Jamaica is, that the estate does not supply tools, the laborers bring their own, such clumsy, heavy, long handled hoes, set at a peculiar slope, are not calculated to do best work. Every man carries a cutlass in the use of which he is an adept: he loves nothing better than to be hacking, or "billing bush." Of spade bars, small weeding hoes, scrapers, they are ignorant; their digger is a harpoon-shaped article stuck on a wooden handle (like a lance) and not fit for heavy holing. I only met with one quintanie amongst my people, called by them "gravel hoe," and finding they were to be got in Kingston sent for dozen and have since used them to much advantage for holing and road work. At job work the creoles do famously, at the ordinary day work they are as bad or worse than average coolies. Petty larceny of fruit and such things is still very prevalent, and as to veracity, it is not to be named; yet you see the churches and chapels usually crowded, the people fond of reading the Bible and singing hymns, yet it is an established fact that 60 per cent of the births in the island are illegitimate. Well did the traveller who visited Jamaica observe that they were fond of church, the singing of hymns, and reading the Bible, yet he noticed their evident great dislike to the ten commandments.

Our climate here is very like that of Uva: the rains come in May and October and November, the latter being equivalent to our big mousoon in India. The rains do not last long, but are often very heavy at the time, causing floods and landslips, of which there are many evidences all round; the flood of 1815 is noted as the worst, and in 1879 a great deal of damage was done. Since 1880, there has been a dry cycle which has been of much benefit to the high-grown coffee, and injurious to the settlers' coffee at low elevations. The sample of Blue Mountain coffee is generally very fine, long canoe shaped beans like Ceylon Rambodda and other high districts. Prices have been much better of late, as there does not seem to be at present a very large supply of colory coffee in the market. A good deal of money has been made by planters and others by purchasing settlers' coffee in the cherry, pulping and curing it properly, and sending it home in barrels with some distinguishing mark from the "bona fide" estate brand. I have heard of one case where 103 tierces were purchased in one season, and, as it probably made from 30s to 40s a cwt. profit, it did not at all turn out a bad speculation. One hears nothing of cwt. here, it is all tubs and tierces; a man asks how many tubs do you get a day, another will say he hopes "to make" a crop of so many tierces.

Another Jamaica "fad" is that your tierces must be made of red American wood; consequently the poor planter has to pay 18s to 20s for a tierce, or about 3s a cwt. for the mere package; whereas in Ceylon all the curing, casking and shipping was done for 4s 6d a cwt. Planters have taken to shipping in old flour barrels which are cheaper and answer as well, as would also the common sorts of Jamaica wood: if any one here would have the moral courage to start the process, and establish a cooperage, which I am sure would pay handsomely. In my next I must give you some specimens of Jamaica English and a few "negro" proverbs which are very clever and amusing.

As to cinchona not much has been done lately. I will write more about what has been done, in another letter. I have heard lately that on the Attorney-General's property on the north side, they have ceased to line and hole, just dibbling in the plants, and giving the men a three-foot stick, to put them in that far apart, but any how as to line and straightness. They also find that such elaborate and expensive nurseries are not necessary, as the seed sown broadcast in ordinary mould and slightly covered over, comes up just as well and strong as when the more expensive process was in vogue. I believe cinchona on this plan on virgin land and a free soil where there are no weeds to fight against, and the land can be cheaply kept clean, until the trees cover the ground and make weeding almost unnecessary, will pay well, even at present prices.

W. S.

Gold in North Borneo.—The communication which Mr. Gibbon has favoured us with (p. 739) is not only interesting but exciting. In the case of ordinary granite, far less than one ounce of gold to a ton of rock pays well, and the North Borneo assay shows the existence in iron dust, which must surely be more tractable than granite, of over an ounce of gold to the ton in Nos. 2 and 4. Such being the case, we suspect the publication of the assay will attract not merely Chinese but European diggers, from Australia in any case and probably from Europe itself. At this moment the world is far more in want of gold than of tin, and, whatever the amount of iron dust or alluvial matter required to be turned over, we should think that gold worth £3 12s an ounce,, at the rate of even half an ounce to the ton, would pay amply: better, we should think, than the stanniferous ore which is now found so abundantly, not only in "Perak" which owes its name to the silver-like metal but in Tasmania and many parts of Australia. Hundreds of millions of ounces of gold might now be thrown into the markets of the world without appreciably affecting the price of the metal (the great medium of the world's exchanges) or the profits of the diggers. Mr. Gibbon can, no doubt, supply information as to the area or areas over which the auriferous sand is spread, to those who determine to go "prospecting" from Ceylon, to take up and work claims and collect rich dust if not nuggets.

Tea Manures.—Mr. Hughes, the agricultural chemist, writes to us:—"I should think you will soon be requiring tea manures. I had a sample of one sent to me from Calcutta which upon analysis appeared rich in nitrogenous organic matter, phosphates and potash, the three important constituents. I was assured this manure had given excellent results on tea estates in India where transit admitted of application."

Planting in Uva, Ceylon.—From Report of Badulla Planters' Association.—*Leaf-disease.*—After a year of singular freedom from the pest, your Committee regrets to have to announce a severe attack at the commencement of this year. *Tea, Cacao, &c.*—The success which has attended the cultivation of cacao and cinchona, and in a small degree cardamoms, is a matter of satisfaction to your Committee, and it trusts that better prices may still further stimulate to cultivation of new products, amongst which tea has already found its place on a somewhat large scale, and bids fair to be as great a success in Uva as in other districts.

Prices of Labour in Sylhet.—Mr. Luttman-Johnson, Deputy Commissioner of Sylhet, has been enquiring into the subject of the prices of agricultural labour in his district. His calculation is based upon wages in kind paid to a reaper at harvest time. In twenty days' working at harvest time, a man might earn about six maunds of rice, enough to support him throughout the year. Reduced into money, the wages amount to five annas a day. In the report for 1882, similar results were shown in his account of wages paid in Sylhet for earth-cutting. Mr. Johnson says that natives of Sylhet will not work in tea gardens for two annas, the ordinary rate paid to tea coolies: but they have earned so much as five annas a day during the year under report. This is about as good a return for agricultural labour as may be found in any part of India.—*Indian Agriculturist.*

The Tea Market.—In casting a glance back on the year just ended, says the *Grocer*, the results of those concerned both as importers and dealers have been anything but satisfactory, while the trade and the public have reaped the benefit of low prices. Although supplies and stocks have been similar since June, yet the new season's teas have been held in such weak hands that forced sales have been necessary to meet future engagements, with results most disastrous to importers and highly unsatisfactory to dealers, the latter being obliged to buy fresh teas each week at lower rates without being able to get out of old stock. There have been several failures and private compositions amongst the importers on this side; and the losses in China both in tea and silk have so crippled many of the large buyers that compositions with John Chinaman have been resorted to. Many of the native banks and teamen have also been ruined by the low prices ruling during the last year or two, and it is to be hoped that supplies will fall off until we recover from the depression on this side. Again, money is likely to be scarce among the native teamen next season, as those that have any left will hide it and get out of the reach of the mandarins, who must squeeze whoever they can, in order to supply funds to prosecute the war with France. We hear from China that the markets are closed for the season, with a short supply of over 8,000,000 lb. This is good news, but we can well do without it, as the consumption of China Congous continues to fall off, while that of Indian and Ceylon increases. Indian and Ceylon tea continues to make rapid strides in favour with the trade, and although the lower and medium kinds do not compare favourably with China kind just at the moment, yet they have gained such a hold on the public palate that the demand and consumption do not fall off. Ceylon teas have been greatly appreciated by the trade and prices have held their own when all other kinds of tea were falling, the demand being greater than the supply.—*Indian Planters' Gazette.*

Greig's Tea Drying, Withering and Winnowing Machine.—In sending an advertisement of their machine for the *Tropical Agriculturist*, Messrs. John Greig & Co. wrote to our London agents on Feb. 2nd:—"We hear now another unfortunate cause of delay in getting our machines set ageing at Dikoya, Ceylon: just as Mr. Brown got everything ready, he broke his leg and is laid up. However a man of ours has just gone out to him; when arrived, all will be put in his charge, and we hope there will be no further delay in obtaining the desired report. But we are obtaining orders from the action of our machine 'XL. ALL' on dry tea and on more delicate material, such as wet feathers, hops, &c., making tea from cauliflower, privet-hedge, and sometimes fresh tea leaf itself grown in open-air botanic gardens here."

Mr. D. Morris, Director of Public Gardens and Plantations in Jamaica, is indefatigable in his efforts to encourage the growth of "new crops" in the West Indies, and it is to be hoped that his efforts will be seconded, not only by planters and others in the Colonies, but also by capitalists in this country. In Jamaica alone there is a wide field for the profitable utilization of capital in the cultivation of new products. A lecture delivered by Mr. Morris before the Institute of Jamaica—His Excellency Sir H. W. Norman, K. C. B., in the chair—has just been republished, in pamphlet form, by Mr. De Souza, of Kingston, Jamaica, and should be read, not only in the West Indies, but in this country and in all our tropical and sub-tropical Colonies. In it Mr. Morris deals elaborately with the various kinds of fibre-yielding plants, native and other, which are or are likely to be of any value for commercial purposes, detailing their modes of culture, and treating of the various methods of extracting the fibre. In this latter direction alone there is room for many mechanical improvements, and a fortune awaits the inventor of a machine which will successfully extract the fibre from, among other plants, the Ramie or Rheea. Mr. Morris suggests, among other points worthy of consideration, the utilization of banana stems for the manufacture of wood or paper-pulp. Each banana stem has to be cut down when once it has borne fruit, and an economic method of utilizing this waste product would add enormously to the value of plantations in the West Indies and elsewhere.—*Colonies and India.* [We have received a copy of Mr. Morris's lecture, which will be reprinted in the *Tropical Agriculturist.*—Ed.]

British Burmah and Rice.—The last Administration Report of British Burmah tells us that nearly ninety per cent (88) of the cultivated area in the province, is under paddy, the cultivation increasing steadily by more than 100,000 acres a year. Out of the 4,000,000 acres under tillage, 232,428 acres are fruit and vegetable gardens. "This kind of agriculture pays well, and that a ready market exists for all orchard and garden produce goes to support the view that the people of British Burmah are well off, and live comfortably." We have frequently pointed out that the calculations of our settlement officers are constantly vitiated, by their uniform failure to take any account of the garden, fruit, and diary produce of the ryot's holding. Whenever these holdings are in the neighbourhood of the cities which are growing up all over India, these items form a most valuable part of the produce, as we here read they do in Burmah. The report tells us that in most parts of the province, the land revenue amounts "to from one-twelfth to one-tenth of the value of the gross produce, and good markets are available directly the rice crop is harvested." The exports from the province are about £9,000,000 sterling a year, the chief items being:—

	£
Rice (paddy)	5,500,000
Cutch and Gambier ...	370,000
Hides	160,000
Timber	1,600,000
Cotton	200,000

The gross land revenue is about £670,000 a year, but the addition thereto of a capitation tax of £300,000 a year, brings the assessments up to nearly £1,000,000 sterling. The general result is that the land bears an assessment of about two rupees and-a-half per acre, the State thus exacting a larger payment from the cultivator, than the so-called rack-rent levied by the zemindar in those provinces under the Permanent Settlement.—*Indian Agriculturist.*

INTERESTING INFORMATION FROM THE WYNAAD REGARDING PURE AND SPURIOUS LEDGERIANAS.

Chembaly Estate, Gudalur, South East Wynaad,
February 10th, 1885.

Dear Sir,—About two years since a discussion took place on the subject of *Cinchona Ledgeriana*, in which Mr. Howard and one or two members of the Linnæan Society at home attempted to throw doubt on the conclusions arrived at by Dr. Trimen, who described *Cinchona Ledgeriana* as a true species. Mr. North Christie who traced the history of the ledgeriana supported Dr. Trimen in his description of the botanical characteristics of this valuable Calisaya, and I think every planter who had the opportunity of watching the Ledgeriana tree could recognize the fact that your authorities in Ceylon fully understood what they were writing about, while the Linnæan Society at home became hopelessly muddled with "macrocarpa," "micrantha," "roja," and the ludicrous conclusions as to the "red leaf."

Guided by Dr. Trimen's description of Ledgeriana I find several trees raised from the original ledger seed; these are chiefly at high elevations on the Nilgheries such as Neddiwuttum, and are identical with the pure type raised from seed whether from Capt. Cox's trees in Wynaad or from the best trees in Java or Ceylon. Mr. T. North Christie in his admirable essay on cinchona cultivation remarks that Java, as regards Ledgeriana, "has had the start and kept the lead by sending out so much spurious seed"—this is true; I am positive that many pounds of seed taken from common Calisayas and sold at cheap rates have found purchasers in India. Ceylon as well as Java has had its share in the export of spurious seed. I have frequently remarked that if planters in Java cannot procure good seed from the pure type of Ledgeriana trees the chances of such seed reaching India are very remote: planters who have obtained seed from such trees as "Mattakellie," "Yarrow," or "St. Andrew's may congratulate themselves on their stock, but I understand, beyond these estates, in Ceylon there are not many possessing Ledgeriana trees. I obtained two small lots of seed from the Madras Government sent to them by the Dutch Government, Java, and said to be Ledgeriana; out of about 350 plants raised I only found six of the true type: the balance were hybrids of all grades. My object in addressing you now is to give a brief account of my experience of 500 seedlings planted out in 1879. In the first place, the seed. This was procured direct from the hands of Mr. Moens, who remarked at the time that it was gathered from his best trees. The seedlings were planted out in two groups in moderately rich soil, in a sheltered corner, northern aspect, elevation 3,100 feet. This estate "Chembaly" lies at the foot of the Nilgheries on the north-west or Wynaad side. The plants throve well: at three years of age a number flowered and about a pound of seed was gathered under the supposition that the trees were Ledgeriana. Subsequent experience however led to the belief that the trees were a mixed lot of Calisayas and some pure Ledgeriana. In order therefore to gauge the value of the different types I sent six samples to Dr. Paul of London, who sent me the following analysis:—

Description of trees from which bark was taken.	% of quinine.	Quinidine.	Cinchonidine.	Cinchonine.	Amorphous.
No. 1. Typical Ledgeriana ...	6·50	0·11	trace	—	—
2. Coarse Pubescent Calisaya	0·98	1·04	—	trace	—
